have been seen in the same eye and two are frequently found. If this does not afford sufficient confusion, the modern treatment of diabetes has so prolonged the life of thousands that they enter the arteriosclerotic time of life.

Before leaving the subject of changes in the retinal blood vessels, I wish to place special emphasis on three correlated and yet sometimes separate conditions. One is malignant hypertension characterized by progressive edema of the disk and an increasingly high blood pressure which does not respond to treatment, frequently

leads to early death and occurs in young males more often than in females. The second is the toxemia of pregnancy with which the retinal expression follows a rather narrow, prescribed course, starting with an isolated spasm of one of the secondary or tertiary branches of the retinal artery. If the underlying cause is not removed, the spasms involve more branches and become more frequent, they become fixed, the hyper-

the fundus of a patient with diabetes can be duplicated in a nondiabetic person, I admit that the picture of yellow exudates arranged without order and not of uniform size, associated with hemorrhage without marked vessel changes, most strongly suggests diabetes. My photographic observations, however, do not warrant the conclusion that this pattern is always and not only caused by diabetes.

Fig. 14—Brain tumor, left acoustic neuroma, right eye of a woman aged 37. swollen disk and surrounding retina full of veins with paralleling exudate. Papilledema.

Fig. 15—Papilledema (choked disk) left eye of a woman aged 60 with left acoustic neuroma. swollen pale elevated nerve head.

tension increases and the usual and ordinary signs of retinal hypertension become manifest. It is therefore imperative that in all cases of toxemia of pregnancy the fundus be examined by a competent ophthalmoscopist who has the requisite knowledge to give advice regarding the management of the patient and to decide when the uterus should be emptied.

The third particular fundus picture is that which develops in the course of malignant endocarditis. It is characterized by flame-shaped hemorrhages usually with white borders or white centers. These are of considerable diagnostic import, for the patient usually dies shortly after they appear.

Furthermore, it is a matter of substantiated, reliable observations that high blood pressure and subsequent arteriosclerosis are concomitant with or even caused by the diabetes. Surely enough has been said to prove the necessity of complete physical and laboratory examinations whenever exudates and hemorrhages are found in the fundus.

Papilledema, or choked disk, is a prominent swelling confined to the disk and immediately contiguous parts of the retina. The central excavation is always demonstrable on stereoscopic examination. In cases of recent involvement the surface is vascular, while in cases of old involvement it is capped with a gray wool-like mem-

Fig. 17—Retinochoroiditis disseminata, right eye of a woman aged 62. depigmented rounded areas of choroidal absorption.

Fig. 18—Retinochoroiditis, left eye of a man aged 50. apical abscesses, teeth removed, large choroidal scar.

Fig. 19—Tuberculous choroiditis, right eye of a man aged 35. two attacks of central choroiditis; the older lesion is the more heavily pigmented.

Diabetes may be severe, last for years and finally cause the death of the patient without producing retinitis. This is a very important point for all physicians to remember. On the other hand, the fundus picture of hard, yellow deposits near the disk or macula combined with small striate or globular hemorrhages may be the first visible evidence of something abnormal and lead to the investigations which disclose the correct diagnosis. There is considerable controversy regarding true pathognomonic infallible diabetic retinitis, and, while inclined to believe that all the changes found in

brane. Papilledema should be considered a sign of intracranial pressure, caused by either an excess of fluid or a tumor, until proved otherwise. If a brain tumor is the first thing suspected, lives will be saved and vision preserved by the prompt recognition and treatment or exclusion of a neoplasm. Choked disk can usually be distinguished from optic neuritis if a careful history is taken, for in neuritis loss of vision is the first complaint and then field restriction and finally the ophthalmoscopic changes are uncovered, whereas choked disk is often discovered in the routine search

for the cause of general symptoms such as headache, and the field changes and visual loss are then revealed.

Syphilis has been sufficiently publicized to need little in the way of further remarks, but there are two special fundus manifestations worthy of comment. 1 Retinochoroiditis as it progresses through a period of an indefinitely outlined swelling to one of paling and flattening to end as a pigmented choroidal white scar.

Many of the blood dyscrasias produce fundus hemorrhages with or without exudate.

Vitamins are widely advertised, and suggestive theoretical indications are often dogmatically expressed as therapeutic realities. A recent phase of this expanding work has led some physicians and many laymen to believe that night blindness is dependent on absence of vitamins and that the administration of the deficient

Fig. 20—Retinitis in pernicious anemia right eye of a woman aged 47 who was seriously ill. The rounded, thick retinal hemorrhages are most suggestive of the blood state.

Fig. 21—Retinitis pigmentosa with night blindness right eye of a man aged 30. Marked contraction of the visual field, retinal reflex greenish disk of a waxy pallor, constricted arteries and veins. The pigmentation is just beyond the limits of photograph.

Fig. 22—Glaucoma right eye of a man aged 55 who was blind. A complete glaucomatous undermining cup of the nerve head.

This is evidence of a severe secondary stage. A patient who has had syphilitic retinochoroiditis seems immune to neurologic syphilis, for I have never seen such a patient have cerebrospinal symptoms. 2 Atrophy of the optic nerve usually of the locomotor ataxic type in which in a most unrelenting manner sight is destroyed by the steady decrease in the size of the visual field. There is a ray of hope for the patient if the modern treatment is administered, but the majority of the afflicted are doomed to darkness after the process is once inaugurated.

Somewhat similar to syphilitic choroiditis is that caused by tuberculosis, which strangely enough fre-

quently attacks those who are considered to be in the full bloom of perfect health. The isolated lesion starts as a small pale area often adjacent to a blood vessel, other tubercles may form, coalesce, heal and recur, or a large conglobate tubercle may be present from the beginning of the fundus disease. Two facts confirmed by repeated observations assist in the diagnosis, one is the relatively slight pigmentation about the lesion and the other is a curious light reflection, a faint phosphorescence, from the thick vitreous opacities.

Finally the routine ophthalmoscopic inspection of every patient will lead to the earlier detection of glau-

Fig. 23—Traumatic atrophy of optic nerve left eye of a man aged 24 sixteen years after automobile accident. The white nerve head is distinctly outlined. Arteries and veins maintain their normal size and relationship.

quently attacks those who are considered to be in the full bloom of perfect health. The isolated lesion starts as a small pale area often adjacent to a blood vessel, other tubercles may form, coalesce, heal and recur, or a large conglobate tubercle may be present from the beginning of the fundus disease. Two facts confirmed by repeated observations assist in the diagnosis, one is the relatively slight pigmentation about the lesion and the other is a curious light reflection, a faint phosphorescence, from the thick vitreous opacities.

comia, which is one of the most serious of all eye diseases. Some day a campaign to prevent glaucoma by the early recognition of field defects and disk changes will be started. The time is opportune, and the need of public instruction far surpasses many of the over-worked fads which take energy and money.

Every physician knows that in glaucoma the central depression in the disk increases in size until in the far advanced stage the entire nerve head is a sunken white cup and the patient incurably blind.

Elderly patients frequently complain of inability to read, this is often correctly ascribed to faint lens opacities or partial atrophy of the optic nerve, but sometimes it is caused by a degeneration in the macular region. The earliest signs are recurring perimacular hemorrhages in one eye and then after months or years in the other. This eventuates in the destruction of the central retina and although the patient is unable to do close work, he never goes blind. A most consoling fact. The seriousness of this situation calls for the mobilization of all physicians in an attempt to understand the method of production, the various stages and, if possible, combat the underlying factors, which at this time seem to be vascular and beyond the range of therapeutic agents.

This article was conceived as a review of actualities to stimulate every physician to use his ophthalmoscope, to recognize his limitations, to call for consultations and by cooperation to continue to uphold the high standard of American medicine, which is second to none because it combines individualistic enthusiasm with scientific accomplishments. When the individual is suppressed productive research always suffers, and this in turn adversely affects the health of the people.

Furthermore, it was intended to concentrate attention on the ocular fundus as one of the most available regions in the entire human body for the recognition of incipient, advancing and destructive processes.

To the initiated examination of the fundus discloses important clinical signs, which, when gathered together, form part of the life record of the patient. From the knowledge gained by the study of thousands of such reports, accurate prognostic as well as diagnostic conclusions can be drawn.

### CONFERENCES ON THERAPY

#### TREATMENT OF SECONDARY SHOCK

NOTE.—These are actual reports slightly edited of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital. The questions and discussions involve participation by members of the college staff, students and visitors.

DR McKEEN CATTELL. In any consideration of the management of secondary shock, a knowledge of the signs and symptoms is an essential prerequisite. Theories of the causation of shock are numerous and diverse. Many of the characteristic changes associated with this condition have been satisfactorily explained. In general, these changes are progressive and serve as a guide to treatment and a measure of the severity of the condition.

The syndrome of secondary shock when fully developed is characterized by the following features: low blood pressure, decreased blood flow, decreased blood volume, lowered temperature and lowered metabolism. Hemoconcentration is an important feature and results in high hemoglobin values. The blood sugar and non-protein nitrogen are increased, chlorides are decreased and the carbon dioxide combining power is low.

These changes are not all present in the beginning and for that reason the condition has commonly been

divided into primary and secondary stages. The syndrome of secondary shock supervenes whenever a low blood pressure or inadequate circulation is allowed to persist. It is important to recognize that there are many causes of low blood pressure, and the end result is much the same whether the low pressure is due to hemorrhage, traumatic injury, burns, nervous manifestations, adrenal insufficiency, diabetic coma, cardiac failure, acute abdominal conditions or the action of toxins such as histamine and many others. All result in a lowering of the blood pressure, and in the initial stages of circulatory collapse there is a condition which is called primary shock. The changes characteristic of secondary shock are undoubtedly initiated at this time, but they develop gradually, usually over a period of several hours. The serious feature of any condition causing a fall in blood pressure is the reduction in the blood supply to the tissues, the patients consequently suffer from an inadequate supply of oxygen and further damage is done to the circulation. A vicious circle is thus set up. Through various secondary readjustments the body tends to maintain blood pressure in the face of blood loss or other damage, so that when it falls below normal limits we may be certain that the safety factor is exceeded and that there is danger of a serious deficiency in the circulation. It has been shown experimentally that when the blood pressure has fallen to about 80 mm of mercury it is not adequate to maintain the normal functions of the tissues. Active therapeutic measures should be instituted before such levels are reached.

The evaluation of therapeutic measures requires a consideration of the mechanism by which the changes characteristic of secondary shock are brought about, and we need especially to know which of the various factors responsible for maintaining the blood pressure are at fault.

There is no evidence whatever that in this condition the heart is in any way inadequate to meet the demands made on it. If it is given fluid it will effectively pump that fluid against even a very high pressure, and thus there is no reason to administer cardiac stimulants.

The vasomotor center continues to act in a normal manner, in fact, it has been shown experimentally that the center is usually in a state of heightened activity, thus tending to compensate for the lost blood and maintain a normal blood pressure. It is true that in advanced shock the vasomotor center along with the other centers does fail, but this occurs only after the pressure has been low for a long period and represents a terminal condition.

An outstanding feature is a diminution of circulating fluid. The blood vessels contain less than the normal quantity of blood, and the amount returning to the heart is much reduced. Where is the lost blood? In the case of hemorrhage the answer is obvious, but an essentially similar condition occurs in shock without hemorrhage. There is general agreement among physiologists that a reduced circulation results in damage to the capillaries. They are dilated and they apparently become more permeable, at any rate, filtration is abnormally rapid and the blood vessels are unable to retain fluid. The changes are similar to those occurring locally in the formation of a wheal.

Gradually the blood volume is reduced, and the signs and symptoms of secondary shock become increasingly

prominent. The pressure falls and the various compensation mechanisms are brought into action. The fall in blood pressure stimulates the afferent endings in the carotid sinus and elsewhere and the heart rate is thus reflexly increased and the arterioles are constricted. The fluid loss brings about an increased concentration of cellular elements, kidney function is reduced because of the decreased blood flow and low pressure with a resulting increase in blood urea. In addition to increased cardiac rate and vasomotor tone there is other evidence of increased sympathetic activity in the increased blood sugar and sweat secretion. The latter promotes heat loss and, along with the lowered metabolism, explains the drop in temperature. There is general agreement that acidosis is a consequence of decreased oxidation due to circulation deficiency.

Moon, in his recent book on shock, has defined the condition as a circulation deficiency, not cardiac or vasomotor in origin, characterized by a decreased volume of blood, reduced cardiac output (volume flow of blood) and hemoconcentration. The points of attack on this problem from a therapeutic standpoint would appear to be two. The first is to increase the circulating volume of fluid, and the second is to prevent the fluid loss from the peripheral vessels. There is very little basis for the employment of the so-called circulation stimulants. General measures directed toward the conservation of heat and fluids, and also for the promotion of rest, are of the utmost importance and should be given first place in any regimen for treatment and prevention of secondary shock.

#### THE MANAGEMENT OF SHOCK

DR. JOHN E. DEITRICK. The clinical picture of the fully developed case of secondary shock is unmistakable. It is essentially the same irrespective of the underlying cause of the shock. As has been indicated, the disintegration of circulatory function which goes under the name of shock does not have only one cause but many causes. We do not know what these primary disorders possess in common which leads to the same ultimate outcome, namely shock, if indeed there is any such common factor. The significant fact is this: regardless of the clinical condition in the course of which secondary shock occurs, the clinical signs and symptoms, as well as the physiologic derangements of the circulation, appear to be essentially identical in all of them when the state of shock is present.

I may speak briefly, therefore, concerning the outstanding clinical characteristics of shock, especially concerning those which have a direct bearing on the objectives of our treatment. These are: 1. Diminished blood volume. There is of course a diminished blood flow but it is primarily due to the diminished blood volume. 2. Decrease in sodium chloride of the blood. 3. Diminished carbon dioxide carrying capacity of the blood (diminished alkali reserve). 4. Paralysis of the capillaries and extreme degrees of constriction of the arterioles. Dehydration with loss of salts and blood proteins are outstanding phenomena in shock. The abnormal permeability of the capillaries appears to be such that the injection of fluid disappears from the circulating blood with extreme rapidity, even though the blood is concentrated and is greatly in need of the injected fluid.

The appearance of the patient is that of one who is desperately ill. There is extreme prostration. There

is apathy or restlessness and anxiety. The facial expression is often pinched. The skin is very pale and often shows a grayish cyanosis. It feels cold, clammy and moist. There is sweating. The peripheral veins are collapsed. Rather marked thirst is often present. The pulse is rapid and thready. The temperature is subnormal and the blood pressure is extremely low, sometimes almost impossible to record. As the condition progresses the respiration begins to suffer, it becomes shallow and feeble. Respiratory failure seems to be commonly the immediate cause of death. I have seen the heart continue to beat for five or ten minutes thereafter, and even longer when artificial respiration was administered.

The treatment of secondary shock, for the most part, is independent of its immediate cause. Since the blood is stagnating in the periphery and is cooling off rapidly, measures are taken immediately to maintain the body temperature. We wrap the patients in warm blankets and we apply hot water bottles and the electric pad for that purpose. In order to promote better circulation in the brain we raise the foot of the bed above the level of the patient's head.

A large blood transfusion is the most satisfactory way of restoring the blood volume. The restoration of the blood volume is the most important single measure. Most patients will fail to recover in shock if their blood volume has been reduced by as much as one half of their normal. Substitutes for blood transfusion are not as satisfactory. A useful emergency agent which can often be obtained sooner than the blood transfusion is dextrose. An injection of 50 cc. of a 50 per cent solution sometimes produces a beneficial though fleeting effect on the circulation. It may be followed by larger amounts of saline and 5 per cent dextrose solution given as a continuous intravenous drip at the rate of from 1 to 10 cc. per minute. These infusions all lack the protein which helps to keep them in the circulating blood. There is danger in their use in that the large quantities of rapidly diffusible fluid with low osmotic pressure promote pulmonary edema.

A 6 per cent solution of acacia was used during the war to combat the shock of war wounds. This solution produces more lasting increase in the blood volume. I do not favor it particularly, however. I hope the pharmacologists will discuss this substance.

The respiration in patients with shock is very shallow. The carbon dioxide combining power of the blood is low, namely 20 or 30. Because of the acidosis the Boston group has recommended and reported beneficial results from the use of a 5 per cent solution of sodium bicarbonate intravenously. They have also recommended the inhalation of carbon dioxide for periods of five minutes at intervals of five minutes. Both of these measures tend to increase the depth of respiration and promote the return of blood to the right side of the heart.

Morphine sulfate is indicated only when the patient is restless or in pain. The danger of depressing the respiratory center by morphine during shock is considerable. I have seen one patient die of morphine during shock. It should not be used for the patient who lies quiet.

Drugs are generally of questionable value in shock. Digitalis is distinctly contraindicated. Epinephrine is of no value and may be dangerous because it constricts

the arterioles which are already constricted in shock. Caffene is widely used as a stimulant in shock and it apparently exerts some beneficial effect. Strychnine has been employed but the pharmacology of strychnine leaves little to justify its application in the treatment of shock.

It cannot be emphasized too strongly that early treatment holds out the only hope of success in patients with shock. When a patient begins to show peripheral circulatory disturbances which are known to terminate in shock, that is the time to begin treatment. Treatment should be started when the falling blood pressure has fallen only to 90 rather than to 60 or 70. It is preferable to begin treatment in the stage of the primary shock, namely the stage in which the blood pressure has fallen, but before paralysis of the capillary bed has taken place. In the case of severe hemorrhage showing some of the symptoms of shock an intravenous infusion of physiologic solution of sodium chloride may cause marked improvement, but if the low blood pressure has been allowed to continue for a long time with the consequent secondary increase in the permeability of the capillaries the infusion of saline solution may be of no value at all. As has been stated, there is a stage in shock when the capillary permeability is so great that proteins pass readily out of the blood stream, the resulting change of the osmotic pressure of the blood makes it impossible for the blood to hold the injected fluid. In a sense it may be said that measures applied to the prevention of secondary shock in case of failing circulation provide the best outlook. When the patient is seen in a later stage, however, that is, in a stage in which secondary shock is already present, the sooner the treatment the better the results, for the longer the state of shock is permitted to exist the more difficult it becomes to correct it and the higher is the mortality.

#### PHARMACOLOGY

DR CATTELL. Dr Deitrick has mentioned a number of drugs which have been commonly employed in the treatment of shock, but he has left the impression, quite correctly I think, that they represent a comparatively unimportant part of the management of the condition. I had hoped he would commit himself in favor of the use of some of those substances so that I should have had the opportunity of pointing out the lack of a sound experimental basis for their employment.

Of the many drugs which have been used in shock I have time to consider only one or two. A substance of special interest in the treatment of this condition is acacia, because that is a substance which has been very extensively employed in the replacement of lost blood, particularly during the war, when it was often impossible to undertake the more elaborate procedure of blood transfusion.

From a theoretical standpoint acacia appears to be an almost ideal substitute for lost blood because it has a large colloidal molecule which is retained in the blood stream and gives the desired increase in osmotic pressure. Its use was considered at one of our recent conferences in connection with the matter of raising the osmotic pressure of the blood for the removal of edema in nephrosis. It has been successfully employed in many other conditions, particularly in shock and hemorrhage, but severe reactions have been frequent and the question arises as to its suitability for routine use.

Particularly during the war, numerous severe reactions were experienced and there is no doubt that many injured men were killed by the use of acacia. I have seen many that appeared to come under that classification. On the other hand, dramatic results were often achieved in raising of the blood pressure and no bad effects followed. The question of untoward reactions has received much attention, and at the time of the war it was noted that there was a good deal of variation in the effects of different lots of acacia. It was assumed that impurities played an important part in the reactions, and I believe that nowadays when much more highly purified preparations are available bad results are not nearly as common.

But animal experimentation has emphasized the existence of certain drawbacks in the use of acacia, and I would like to mention one or two recent publications on this subject. In the first place, the matter of elimination is important. It has long been known that the elimination of acacia is slow, and this is one of the reasons for its therapeutic value. Acacia is retained in the blood stream for several days and is only gradually eliminated from the body. But small amounts of the total injected can be recovered from the urine and it is not oxidized.

The elimination of acacia was recently studied by Andersch and Gibson of the University of Iowa. In a series of eight rabbits they examined various organs to find out where this material was stored and were able to recover from the liver on the average about 50 per cent of the total amount of acacia injected. Analyses made several months after the injection of the acacia showed a large percentage of the total amount injected to be still present. They also made histologic studies and got evidence indicating that this was not entirely an innocuous condition. The cells were full of vacuoles, presumably containing the acacia, and there was definite interference with the formation of bile. The same thing was true in rats and dogs and in one human being whom they examined. This patient had received acacia over a period of several months, and more than 40 per cent of the total acacia injected during that period was recovered from the liver. Further, in regard to the manner of excretion it is of interest that acacia was found to be eliminated in the bile and thus gradually excreted.

There is the further fact that in using acacia rather than whole blood one is not using the most favorable possible substance, because the oxygen-carrying capacity of the blood is not thereby increased. This point has been emphasized by Yandell Henderson, who carried out experiments on dogs bled a certain standard amount, causing approximately 50 per cent of them to die if not treated. In those animals, all of which recovered if blood was reintroduced, the chances of survival were not improved by the use of acacia. For that reason Henderson emphasized the importance of the red blood corpuscles in the treatment of shock and he thought that they constitute an essential part of any procedure for replacing lost blood.

Perhaps it will be just as well to leave the remainder of the period for discussion, and if there are points that come up in connection with the other substances mentioned by Dr Deitrick I think several of us are prepared to say something about them.

DR HENRY B RICHARDSON If a dog receives acacia and nothing else, what is the effect on its longevity?

DR CATTELL That was not studied in the experiments referred to. However, I think no bad results have been reported from the injection of acacia into animals other than the type of finding reported by Andersch and Gibson. Those animals were not killed by the acacia.

STUDENT I wondered if there was any experimental evidence supporting the use of caffeine as a cardiac stimulant.

DR CATTELL I think that the use of caffeine rests on a very unsound experimental basis. I am not familiar with the clinical experience in the use of caffeine, but from a pharmacologic standpoint it can be said with a good deal of emphasis that it has no value as a circulatory stimulant. The actions are rather mixed, there being a central action which tends to cause constriction of the peripheral vessels and a slowing of the heart, and a direct action on the musculature of the arterioles causing them to relax. The net effect on blood pressure is very slight. I believe that in therapeutic doses no appreciable action could be expected from the use of caffeine. Its use as a respiratory stimulant might be considered. I feel that in shock there is very little indication for the use of respiratory stimulants because in general there is no evidence that the circulating blood contains less than the normal saturation of oxygen on leaving the lungs, and the slow respiration is probably to a considerable extent secondary to the general depression of bodily functions.

STUDENT Is the profound psychic depression due to anoxemia and low pressure or is there any experimental evidence showing that there is edema in the central nervous system causing a depression in shock?

DR CATTELL I think there is an adequate basis for the depression in the generally reduced level at which activities are carried on under the circumstances of a deficient circulation.

STUDENT I should like to ask Dr Cattell, in line with what he said about caffeine, whether the diuretic action of caffeine, by increasing the dehydration, is contraindicated.

DR CATTELL I think not. In a condition of this sort where there is dehydration a diuretic is usually ineffective, and while I cannot speak from experience, I should feel that that would not be an important consideration.

DR DEITRICK I have seen caffeine and epinephrine given by intracardiac injection when the patient's respiratory center had ceased functioning for ten minutes and the patient's respiratory rhythm was reestablished for another half hour. Dr Wolff saw the patient with me along with several others. There was no doubt that the respirations had absolutely ceased. We were giving artificial respiration while the nurse was getting the caffeine and epinephrine ready. The respiratory rhythm came back after injection but the result was only temporary and we could not maintain it.

DR HARRY GOLD The stimulant action of the xanthines on the respiratory and the higher centers is really very striking sometimes. In patients with uremic coma and patients with Cheyne-Stokes respiration as a

result of advanced heart failure, consciousness is restored and Cheyne-Stokes respiration is abolished. Consciousness is sometimes restored for a period long enough to enable the patient to sign his will.

DR BRUCE HUNT, Perth, Australia What preparation is used?

DR GOLD Caffeine with sodium benzoate in a dose of about 1 Gm intravenously, but injected slowly, taking two or three minutes for the injection, or aminophylline in a dose of about 0.25 or 0.5 Gm injected intravenously. A contraindication to the use of caffeine one might possibly find in the observation of Grollman, namely that the cardiac output is increased by large doses of caffeine but the oxygen requirements are increased to about the same degree, about 20 per cent increase in oxygen uptake, associated with an increase in cardiac output. The drug is therefore imposing an added load on the heart rather than relieving it.

STUDENT I should like to ask Dr Deitrick whether there is a toxic substance liberated in an injured limb and how effective a tourniquet might be.

DR DEITRICK Work has been done on that. If you crush a limb tying the artery first, the animal will not go into shock. If you tie the vein leaving the artery intact and crush the limb, the animal will go into shock. That is important. The best observers have been unable, however, to demonstrate a substance which is carried in the blood and which will produce shock or even a drop in blood pressure, such as histamine-like substances in the blood of the femoral vein of a crushed leg. Histamine shock at autopsy gives quite a different appearance from that of a patient dying from shock following blood loss.

DR EUGENE F DU BOIS Dr Cattell, have you any comments to make on that? I want to introduce a little divergence of opinion in this discussion.

DR CATTELL I feel that that possibility would be very difficult to rule out. It is of interest that recently there have been reported by Feldberg experimental studies in which an increase in histamine has been demonstrated in shock produced by snake venom and by certain bacterial toxins. The amounts of histamine are extremely small. However, large amounts may not be required to produce damaging effects when liberated over a period of several hours. I believe that our methods of determining histamine are so crude at the present time that it would be extremely unlikely that such a demonstration could be made. It is important, nevertheless, that in cross transfusion experiments this type of reaction cannot be easily demonstrated, an observation which would seem to imply at least that under favorable circumstances the animal will be able to cope with whatever quantities of histamine may be formed.

DR DU BOIS Do you think histamine is an important factor in medical and surgical shock?

DR CATTELL In experimental shock Dr Cannon and I thought that histamine might play a part, but I think the proof for that is yet to be obtained.

DR DEITRICK Histamine can be detected if injected into an animal in small amounts, that is in an animal that has a crushed leg. If the venous blood returning from that leg is injected into another animal a fall in blood pressure occurs, but no similar effect has been demonstrated in blood from the crushed leg itself. I

think that Dale agrees there is very little evidence that histamine has any real effect in traumatic shock.

DR CATTIL: It is interesting that the liberation of potassium has been recently considered as a cause of shock. At Columbia Scudder and his associates feel that potassium set free in tissue damage is important. As you know, potassium is present in relatively high concentrations inside the cell, a matter of 300 or 400 mg per hundred grams of tissue as compared with only about 20 mg per hundred in the blood and therefore the release of a relatively small proportion of that present would bring about a toxic concentration in the blood stream.

DR RICHARDSON: Is there a change in the concentration of sodium chloride analogous to that in Addison's disease?

DR GOLD: There is a fall in the sodium content of the blood serum in shock. Isn't salt useful in the treatment of shock?

DR DEITRICK: We prefer to use sodium bicarbonate in order to supply the sodium ion. The carbonate may be lost through the lungs as carbon dioxide. Its use would tend to increase the alkali reserve.

DR DU BOIS: Dr Deitrick, I should like to ask a few questions about the amount and strength of dextrose or saline solution that you give whether or not you give them in combination, and also the method of preparing relatively sterile solutions of sodium bicarbonate.

DR DEITRICK: I will answer the last question first. I have had to prepare sodium bicarbonate solutions on several occasions. I don't know how the Boston group prepared their solution. We use sterile doubly distilled water and simply add the sodium bicarbonate to it to make a 5 per cent solution. You cannot add the sodium bicarbonate and then sterilize it for if you do the salt is broken down.

As to the dextrose or saline solution, you can use either. I would use 5 per cent dextrose or physiologic solution of sodium chloride or sometimes even a mixture of the two. Their action is very transitory so I think they ought to be used only until you can get blood or acacia. I would not have any objection to using acacia to tide the patient over, but I would not want to keep on giving acacia. It comes in large sealed ampules, and I have given it to patients in cases in which I think there is urgency in the face of a falling blood pressure. Blood banks may make it simpler to treat these patients in the future.

DR DU BOIS: I presume you all know what a blood bank is. It is an accumulation of many varieties of blood in an icebox so that almost any need can be supplied.

Before leaving this subject I presume that in preparing the bicarbonate you put into it the cooled water, so that there would be no danger of its changing into a carbonate, and that you ladle it out from a clean container.

DR HUNT: Do you find any practical justification for the use of the hypertonic saline in preference to the regular saline solution?

DR DU BOIS: I was going to ask that question and also about hypertonic dextrose. Can you withdraw some of the fluid from the tissues by using the stronger concentration of dextrose?

DR DEITRICK: Yes, there is experimental work indicating that you can. As concerns hypertonic saline solution I think it can be shown that it will increase blood volume for a period of perhaps fifteen or twenty minutes, and then the effect is lost. Some change seems to occur, however, so that the loss of fluid from the blood from then on becomes more rapid. I don't understand why but this has been shown by careful work.

DR DU BOIS: There is also the possibility that in using the too concentrated solution of dextrose you might produce a glycosuria and diuresis.

DR GOLD: What about the thrombophlebitis caused by concentrated solutions of dextrose, the 50 per cent solutions?

DR DEITRICK: I have seen thrombosis produced after only one injection of a concentrated solution of dextrose and if you repeat the injections in the same vein it almost always occurs.

STUDENT: What concentration of saline solution and of dextrose would be given?

DR DEITRICK: We usually use 5 or 10 per cent dextrose. Large amounts of this fluid are not without danger. In experiments on dogs large injections of dextrose and saline solution have caused death with pulmonary edema. Physiologic solution of sodium chloride (from 0.85 to 0.9 per cent) is the one we commonly use.

DR HUNT: What is the routine on this procedure in the emergency ward?

DR DEITRICK: We have saline and dextrose solutions which we can get within five minutes. I don't believe there is any acacia available in the accident room now, is there?

INTERN: Not that I know of.

DR GOLD: I should like to ask Dr Deitrick when he considers or by what signs he considers the patient in whom the blood pressure has fallen to be in a state of secondary shock. Where does one draw the line?

DR DEITRICK: I think that in the interest of good therapy we ought to define shock as existing before the typical picture develops. Shock, to me, already exists when the blood pressure has dropped to 70 and when the blood volume reaches 50 or 60 per cent of normal. The hemoglobin determination proves misleading because it may be high as the result of concentration of the blood. I don't believe a patient should be allowed to remain with a systolic pressure of 90 without something being done to increase it. How one proceeds depends on the rate of the fall of the blood pressure. If you are watching a patient who is bleeding and the blood pressure is 100/60 and an hour later it is 100/50 and in twenty minutes later it is 90/50, I think it is now time to intervene. It is not so serious if blood pressure falls more slowly to 90 over a period of six or eight hours and then begins to level off. One ought to keep a very accurate graph of what is happening to the blood pressure and pulse, so that one may see how rapidly the circulation is changing. If it is changing rapidly, I wish to step in much sooner than if it is changing slowly. In a case of internal hemorrhage, the body should be given a chance to compensate for a hemorrhage and to stop it. When to interfere is a matter which requires considerable judgment and as full a knowledge as possible of the course of events in the individual case.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION  
OF THE FOLLOWING REPORTS

HOWARD A CARTER Secretary

### WESTERN ELECTRIC AUDIPHONE ORTHO-TECHNIC MODEL ACCEPTABLE

Manufacturer Western Electric Company, 195 Broadway,  
New York

The Western Electric Audiphone, Ortho-Technic Model, is a carbon microphone hearing aid. It is assembled from parts designed to provide different frequency response characteristics. After the individual's hearing loss has been measured the parts are selected which will best meet his requirements. The equipment consists of microphone, air and bone conduction receivers, amplifier, batteries (supplying 3 and 4½ volts), head band, cords and receiver tips. The parts are finished in polished black.

The unit was tested by a competent investigator and the following report made:

**Microphones**—Two carbon particle barrier type microphones, lentil shaped with disk diameter of 3 inches and thickness of three-fourths inch, were submitted. The carbon chamber in these units is filled full of carbon particles instead of three-fourths full as in the ordinary and earlier types. A four-spoked current control rheostat adjustment is on the front. An attachment slip is on the back while a jack for a connecting cord is placed at the bottom.

Western Electric Ortho-Technic  
Model Audiphone

To test the frequency response characteristics of a microphone, it was included in a series circuit with a 45 volt dry battery and a 30 ohm resistor, since it had been previously established that the hearing aid circuit in which the microphone is normally used had a resistance of

30 ohms. Then the transmitter was placed in a sound chamber which was free from reflections and subjected to pure tones of constant intensity and varying frequency. The voltage across the resistor is a measure of the electrical output of the microphone, and this voltage was impressed on the input terminals of a cathode ray oscilloscope and measured as the frequency was varied. The results for the two microphones in question are shown on graph 1.

It will be observed on studying these curves that the principal difference between the two response characteristics is that 637A-3 has a larger output than 637B-3. The general trends of the two curves, however, are quite similar, certain characteristic peaks and valleys being present in both. It may be said, that, on the whole, the response is relatively well sustained over a frequency band of from 250 to 4,500 cycles per second, without the presence of extreme response peaks.

It was also possible to observe the wave form of the electrical output of the microphones on the oscilloscope screen and it was observed that the output was for the most part fairly free from harmonic distortion.

**Air Conduction Receivers**—Three air conduction receivers were supplied. All are of the permanent magnet miniature type, furnished with a hard rubber tip which snaps onto the receiver and is intended to conform to the inner contours of the outer ear. The receivers are about seven-eighths inch in diameter and one-half inch deep with connecting cord jack at the bottom. The jack accommodates one large and one small pin so arranged that the polarizing current cannot flow in the wrong direction.

The receivers were tested individually as to frequency response by supplying them with current of varying frequency and at constant terminal voltage. The acoustic output of the receivers was impressed on an artificial ear. The electrical output of the artificial ear was then observed on a cathode ray oscilloscope. The results are shown on graph 2.

It will be observed by referring to the curves that receiver WE 709A-3 (marked with two dots) peaks at about 1,200 cycles and that receivers WE 709B-3 (marked with one dot) and WE 709C-3 (no marks) have response characteristics similar to A but with main resonant peaks shifted up in frequency by 400 and 1,400 cycles respectively. In the main it would be true to say that the B and C curves are similar to the A curve but are referred to different frequency scales.

#### Carbon Particle

**Amplifier**—The amplifier was made of molded bakelite approximately 1¾ by 1¾ by 1 inch in size. Through the bottom projected four split pins fitting into corresponding jacks in the battery. Receiver and microphone cords plug into poled jacks situated on the top of the amplifier, and at one end is an on-off switch. The amplifier was found to operate equally well in all positions and accordingly it is assumed to be a carbon particle barrier microphone magnetically operated. The battery used with the amplifier consisted of two separate 45 volt batteries held in one container and terminating in two separate jacks. The microphone circuit and the receiver circuit are entirely separate electrically, being coupled only in a mechanical sense in the magnetically operated microphone. The double battery arrangement eliminates the defect of singing due to electrical coupling entirely.

**Battery Consumption**—When the amplifier and the two 45 volt batteries of the GB-45 battery unit were used, the current in the amplifier-receiver circuit was approximately 20 mls and in the microphone amplifier circuit the current varied from 20 to 23 mls with rheostat full on. For the lowest rheostat setting the latter current was found to be 6 mls.

The measurements were repeated, the 3 volt GB-3 battery unit being used. A current of 9 mls was measured in the receiver circuit, and 14 mls and 4 mls in the microphone circuit for maximum and minimum rheostat settings respectively.

**Intelligibility and Articulation Tests**—The measure of actual usefulness of a hearing aid depends largely on the faithfulness with which sounds are amplified. Consequently a controlling element in any judgment of its merit must be its actual performance. Tests were accordingly conducted.

One departure from the usual test method was made in that the output of the hearing aid, instead of being reduced in volume by an artificial ear circuit, was reduced in its own electrical circuit by a resistance pad so designed that the microphone operated with its rated current. The hearing aid receiver under these circumstances was not subjected to full speech current amplitudes, but it had been previously determined that the distortion introduced by the receiver was inconsiderable. The amount of speech volume loss introduced by the resistance pad in order to produce sounds in the ear of the same loudness as when directly listened to was taken as the measure of the hearing aid amplification. It is believed that this method of test is superior for the purpose to the one employing additional

Graph 1

Graph 2

transmission links with the necessary acoustic coupling devices. Experience indicates that the results obtained are consistent.

Both discrete sentence intelligibility and articulation tests were conducted, as well as an amplification determination. Owing to the number of receivers and microphones available, a rather large number of combinations is possible. From the response characteristics of the individual items a combination was selected which represented the one most favorable for normal hearing. It was later found, however, that the most extreme combination possible did not materially affect the conclusion. The results obtained are given in the table.

As an additional test a list of difficult, unfamiliar, telephone directory names with two initials was transmitted over the hearing aid. The results are given in the 5th column of the table. Also, in order to determine how much loss in articulation was produced by the room itself and the manual listening method, a test was conducted as follows. The

Summary of Results

Hearing Aid Combination	Sentence Intelligibility	Con Vow Con Articulation			Difficult Telephone Directory Names with 2 wo. S. initials	Intensity Gain in Decibels Rheostat Maximum
		Con	Vow	Syllable		
No amplifier microphone 674-3 battery 4.5 volts	89.0%	87%	90%	70%	80%	4-10
Amplifier microphone 674-3 receiver 700B-3 battery 4.5 volts	99.5%	70%	90%	60%	10%	20-24
Test room only direct conversation one ear covered		92.7%	95%	85%		

observer tightly covered one ear with a jar stuffed with cotton and listened to con-vow con syllables spoken in a normal tone on the side of his covered ear. The results of this test are given in the last line of the table. It will be observed that there is a considerable loss, 15 per cent, in syllable articulation.

**Bone Conduction Transmission**—Similar tests were conducted with the same items as shown in the second line of the table except that the receiver was replaced by the 710A-3 bone oscillator. The results obtained as to sentence intelligibility and articulation were almost identical with those in line 2.

In view of the foregoing report, the Council on Physical Therapy voted to include the Western Electric Audiphone, Ortho Technic Model, in its list of accepted devices.

### BURDICK SURGICAL DIATHERMY, MODEL D-3, ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

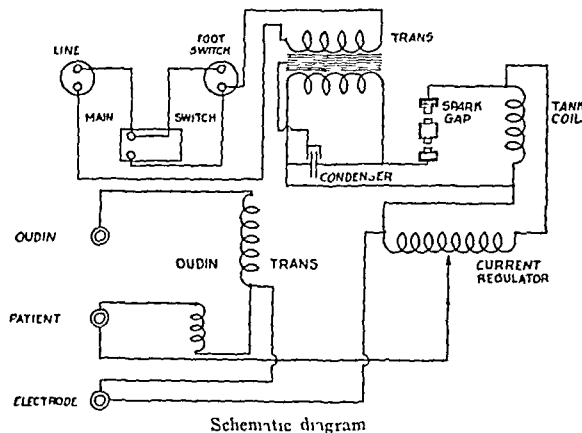

The Burdick Surgical Diathermy Unit, Model D-3, is recommended for surgical and for limited medical purposes. It is primarily a surgical unit producing currents for electrocoagulation and desiccation. It is adaptable for moderate diathermy use. This portable unit comes in a leatherette covered cabinet with carrying handle on top. The dimensions are 14½ inches long by 10 inches wide by 6¾ inches high or 9½ inches high with cover. It weighs 25 pounds. There is a compartment in the cover for foot-switch, cords and electrodes. The standard equipment includes foot-switch and cords. Surgical electrodes are optional.

Designed to provide a low voltage and high amperage current for electrocoagulation purposes and to produce an Oudin high voltage current for desiccation and fulguration, the unit operates by spark gap. Four three eighths inch tungsten points mounted on radiators turned from solid stock have gaps in fixed position. The transformer is the low voltage, air-cooled type. Data submitted by the firm on temperatures observed for spark gap, transformer and cabinet interior taken after six hour runs at full load, were within the limits of safety. The condenser is made of mica and copper plates. According to the firm, minimum high frequency losses occur with this resonator wound on bakelite tubing.

Burdick Surgical Diathermy Model D-3

The intensity is regulated by means of a single control, the micro inductive switch. This provides minute regulation of current from zero to the full range of the apparatus. The firm states that this precision control enables the operator to duplicate dosage by recording the settings used for a given size of electrode and certain type of work.

Schematic diagram

The unit was investigated clinically by a qualified physician and reported to give satisfactory service. However, it was pointed out that because of the length of the electrode handle, 14 inches, it is often necessary in performing fine work to slide the hand down over this insulated section to gain control of workmanship. The soft rubber insulation of the electrode tips does not prevent heating when a strong current is used.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Burdick Surgical Diathermy, Model D-3, for inclusion in its list of accepted devices.

### WAPPLER SHORT WAVE DIATHERMY MACHINE, MODEL C-507, ACCEPTABLE

Manufacturer: American Cystoscope Makers, Inc., Compression Division, 450 Whitlock Avenue, New York.

The Wappler Short Wave Diathermy Machine, Model C-507, is recommended for medical and surgical diathermy, including hyperpyrexia treatments. It is similar to the Compex Short Wave Diathermy previously accepted by the Council (THE JOURNAL, April 25, 1936, p. 1468) except for the addition of the inductance coil technique. The former model was investigated with pad and cuff electrodes. Due to the merging of the Compex Oscillator Corporation with the American Cystoscope Makers, Inc., the name of the Compex Short Wave Diathermy has been changed to Wappler Short Wave unit to conform with the established trade name "Wappler" covering all of the products of the American Cystoscope Makers, Inc. Storage space is provided by means of a drawer. The complete unit weighs 125 pounds.

According to the firm, the circuit employed is identical in all respects with the two tube type used in the Compex Short Wave Diathermy and has, in addition, an impedance matching circuit permitting inductance cable appliances. Both units have a 15 meter wavelength. The

Wappler Short Wave Diathermy Machine, Model C-507

transformer temperature rise and the rise at various levels within the cabinet after a two hour run at full load, were low enough to satisfy the requirements for fire hazard. When the unit is

used with pad and cuff electrodes, it is claimed to perform exactly as the accepted model on the basis of the tests made on the circuit similar to that employed in the Compres machine

As evidence of the ability of the unit to produce deep heating, the firm submitted six tests performed with the thermocouple technic recommended by the Council

Average temperatures for six observations with the inductance coil technic are given in the accompanying table

Schematic diagram

The unit was tried out in a clinic acceptable to the Council and performed satisfactorily

In view of the foregoing report, the Council voted to accept the Wappler Short Wave Diathermy Machine for inclusion in its list of accepted devices

## Council on Pharmacy and Chemistry

### REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
PAUL NICHOLAS LEECH Secretary

### THE PRESENT STATUS OF CYCLOPROPANE

The Council stated in a preliminary report on cyclopropane<sup>1</sup> that the anesthetic could not be properly evaluated because adequate evidence was not available. Since then much clinical and pharmacologic evidence has become available. The evidence is considered in this report.

Seevers and Waters,<sup>2</sup> in their review of the pharmacology of anesthetic gases, note that when an attempt is made to list the qualities which are expected in the "ideal" anesthetic gas "the desires of four individuals must be considered." The patient desires a rapid induction without irritation or unpleasant odor and comfortable recovery, the surgeon wants a nonexplosive agent which effects complete muscular relaxation and does not increase the capillary bleeding, the anesthetist desires a good margin of safety with a minimum of functional or organic injury, adequate potency for high oxygen mixtures and elimination of the unchanged chemical and "moment to moment" control of the depth of anesthesia resulting from rapid interchange of this gas between the atmosphere and the tissues, and the manufacturer hopes for an agent which can be produced simply and inexpensively, is easily purified and remains chemically unchanged during storage.

There is no known gas which meets all the requirements specified, but the experimental and clinical evidence for cyclo-

propane is considered herewith on the basis of these standards set by Seevers and Waters. Lucas and Henderson<sup>3</sup> introduced cyclopropane for clinical use in 1929 after a preliminary pharmacologic study. Later a preliminary report of 447 clinical cases was published by Stiles, Neff, Rovenstine and Waters<sup>4</sup> in 1934. Other early workers included Griffith,<sup>5</sup> Bourne<sup>6</sup> and Wood.<sup>7</sup> A complete bibliography to date would include more than a hundred references to the use of this agent. The following information is designed to include the pertinent contributions of the many authors who have published reports on this anesthetic gas.

#### CHEMICAL AND PHYSICAL PROPERTIES

Cyclopropane ( $C_3H_6$ ),  $\begin{array}{c} H \\ | \\ H-C-\Delta-CH \\ | \\ H \end{array}$  described by von Freund<sup>8</sup>

as trimethylene in 1882, is a colorless gas with a characteristic, not unpleasant odor. Its molecular weight is 42.1, its density at 0°C and 760 mm of mercury is 1.46. The boiling point of cyclopropane is  $-32.89^\circ C$ <sup>8a</sup> and the freezing point  $-126^\circ C$  [Unpublished data from the laboratories of the Ohio Chemical & Manufacturing Co., Cleveland, Ohio, indicate a boiling point of  $-32.2^\circ C$ , and a freezing point of  $-127^\circ C$  for cyclopropane.] It is inflammable and explosive.<sup>9</sup> The lower limits of explosibility are the same as for ether, but the upper limits are much less.<sup>10</sup> The range in air of explosibility is from 3 to 8.5 per cent and in oxygen from 2.5 to 50 per cent.<sup>11</sup> The olive oil to water solubility of an impure cyclopropane gas is 64.4 to 1 as compared with 13.2 to 1 for ethylene and 25.5 to 1 for ether.<sup>3</sup> The oil-water coefficient of pure cyclopropane at  $37.5^\circ C$  is  $34.31$ .<sup>12</sup> Many authors have reported on its solubility<sup>13</sup> in water, in blood (both human and animal), in various oils by saturation and extraction and in iodine pentoxide. According to Orcutt and Seevers<sup>12</sup> who used the extraction method, it has at body temperature a solubility in water of about 20.4 volumes per cent and in human oxalated blood 45.7 volumes per cent. The solubility in cod liver oil and paraffin oils is approximately the same as for olive oil, which is 699.0 volumes per cent. According to Robbins,<sup>14</sup> its solubility in blood varies with changes in cell volume as well as in the lipid content of the blood and, therefore, is increased after a fat meal.

#### PREPARATION OF VARIOUS BRANDS

The Ohio Chemical & Manufacturing Co. presented its brand of cyclopropane to the Council three years ago. Presumably this product, as well as two other brands—E. R. Squibb & Sons and Imperial Chemical Industries, Ltd.—is manufactured after the method of von Freund.<sup>8</sup> Subsequently, Haas<sup>15</sup> described a new method of preparing the chemical. This method was

patented by Purdue University and subsequently sold to the Mallinckrodt Chemical Works, makers of the latest and third American brand

## IMPURITIES

Burger<sup>16</sup> studied the impurities in all three American brands, referring to them as brands A, B and C. He logically predetermined the likely impurities and noted that the manufacture of the gas required ring closure (ringschluss) and that the "chloride" method was apt to result in the formation of propylene. Wolkow and Menschutkin<sup>17</sup> had noted this previously and Wilstaetter and Bruce<sup>18</sup> had described methods for eliminating propylene. Ipatjew<sup>19</sup> changed 50 to 70 per cent cyclopropane to propylene by passing it over iron filings at 100 C. Burger believed that not only propylene but cyclohexane was likely to be present. It is difficult to detect either, since the two have the same composition (the same empiric but not the same structural formula) as cyclopropane. Burger employed the Wagner<sup>20</sup> cold permanganate method and the Gustavson<sup>21</sup> iodine absorption procedure and found that by the former, brand A contained 285 per cent propylene, brand B 256 per cent and brand C 0.12 per cent. Results by the latter method checked closely—brand A contained 280 per cent, B 250 per cent and C 0.14 per cent of propylene. Burger did not claim that these tests were positive but merely that propylene was the most likely compound to give positive results of these tests. He could devise no test for the presence of cyclohexane but was suspicious of its presence because of the similarity of odor to that of chloroform, even though the test for haloids was negative. In his opinion cyclohexane was more undesirable than propylene, but he also believed that it could be eliminated by careful fractional distillation. Buchman and Wardell<sup>11</sup> have stated that propylene, propane, higher hydrocarbons, ethers, alcohols, alkyl halides and nitrogen are the impurities which are most likely to be encountered in cyclopropane.

## CONCENTRATION, SATURATION AND DIFFUSION

Cyclopropane differs from other gaseous anesthetic agents in that the anesthetic-oxygen ratio is reversed—15 per cent of cyclopropane to 85 per cent of oxygen up to the rarely and briefly used 40 per cent of cyclopropane and 60 per cent of oxygen.<sup>22</sup> Robbins<sup>23</sup> found in seventeen dogs that abdominal relaxation required 168 mg per hundred cubic centimeters of blood that loss of the wink or lid reflex required 206 mg in 100 cc, and that costal paralysis ensued when 255 mg of the anesthetic was present and respiratory arrest occurred when 100 cc contained 282 mg of cyclopropane. Seevers notes that this gas possesses analgesic properties in subanesthetic concentrations of from 3 to 5 per cent if continuously inhaled.<sup>24</sup> Most normal persons will lose consciousness following prolonged inhalation of 6 per cent or less although effective concentrations vary widely with the person.<sup>25</sup>

Romberger<sup>25</sup> points out, however, that nothing could be farther from reasonable physiologic truth than that set percentage mixtures of cyclopropane-oxygen are indicative of definite places or levels of anesthesia. Furthermore, he points out that the exact percentages are indeterminate unless minute to minute samples are taken. He concludes that since the use of ether and the open mask gives no index of percentages, it is necessary to use signs, the same index should be used with cyclopropane.

Barbour<sup>26</sup> stated that "the amount taken up by the blood is directly proportional to the partial pressure of the gas existing in the alveolar air and to the solubility coefficient for that particular anesthetic." According to Robbins,<sup>27</sup> blood cells absorb about two and one-half times as much cyclopropane as blood plasma. He found the distribution coefficient (blood concentration/air concentration) in the dog to be 0.492 in vivo and 0.513 in vitro—a good agreement. Concentration of cyclopropane in the blood of the right side of the heart is practically equal to that in the arterial blood after fifteen minutes of anesthesia.<sup>27</sup> That complete body saturation does not occur at this time (but several hours later), is indicated by Seevers' data<sup>28</sup> on the dog and rabbit by the gas depot method. Similar data have been obtained on man by the same method.<sup>29</sup> Appreciable quantities of the gas are lost to the tissues throughout an ordinary anesthesia.<sup>30</sup>

When the pressure gradients are diminished as saturation or desaturation is approached, the diffusion rate is much prolonged, as indicated by Robbins' data showing that the venous blood still retained some cyclopropane after from two to three hours of cyclopropane. The rate of diffusion of cyclopropane appears to be about twice that of ethylene.<sup>31</sup> That ethylene is eliminated more rapidly than cyclopropane may be inferred from the difference in potency and the fact that induction and recovery are slower with the latter agent. Romberger, using Ronzoni's<sup>32</sup> data for ether, found that cyclopropane was eliminated much faster than ether.

## PHARMACOLOGIC EFFECTS

**Heart and Circulation**—Waters notes that the entire effect of this agent on the vascular system, coronary vessels and myocardium is not established, but nevertheless certain facts are available. Waters and his associates<sup>33</sup> and Sise<sup>34</sup> have both warned that if bradycardia, arrhythmias or tachycardia developed during cyclopropane anesthesia the concentration must be lessened at once. Lucas, Henderson and Waters noted that high concentrations of cyclopropane produced cardiac arrhythmia in experimental work on animals and man. Seevers and his associates<sup>35</sup> observed these arrhythmias just prior to or following respiratory arrest in concentrations of over 35 per cent in dogs. Robbins and Baxter<sup>36</sup> concluded that the arrhythmias occurring after respiratory arrest in the dog are due to anoxemia and not to cyclopropane per se, since they occurred when the arterial blood contained only 28 per cent oxygen, and that vagal section did not prevent them, although it did prevent the increase in the PR interval and the more severe type of auriculoventricular block which occurs earlier in anesthesia. Seevers and his associates thought that early arrhythmia was of vagal origin, since it was prevented by atropine and was not entirely due to anoxemia, even though this was a factor and plays a major role in the arrhythmia occurring later. Waters<sup>30</sup> studied the incidence of arrhythmia clinically and found that it increased with deepening cyclopropane anesthesia and lessened with deepening ether anesthesia. Kurtz, Bennett and Shapiro<sup>36</sup> encountered four cases of multiple focus ventricular tachycardia in a series of forty-one clinical administrations purposely carried to the

fourth plane, which indicates, as do certain animal experiments, that since the irregularities are of ventricular origin there is increased irritability of the automatic tissue of the heart. The work of Moffitt<sup>37</sup> indicates that bradycardia occurred most frequently with cyclopropane majors followed in order by ethylene minors, ether majors and nitrous oxide majors.

Eversole<sup>38</sup> studied cardiac irregularities in 109 patients receiving 113 anesthetics and encountered cardiac irregularities in 79 per cent of the cyclopropane cases, 90 per cent of the ether cases and 100 per cent of the chloroform cases. The disturbances were frequently pacemaker displacement or sinus arrhythmias. Thirty one of the group had cardiac irregularities preoperatively. Tachycardia occurred in four of the cyclopropane cases. Marshall<sup>39</sup> believed that arrhythmia, bradycardia, and tachycardia were closely related to increased concentrations. In 7,200 administrations with which Waters was familiar there were three deaths, one of which was a preanesthetic circulatory failure and the other two were probably due to ventricular fibrillation. They were attributed to technical errors of administration, for although fine concentrations were used for induction it was increased rapidly through respiratory depression. Simmons<sup>40</sup> reported one death in ventricular fibrillation.

Some interesting light is thrown on the subject of the relationship of cyclopropane to these rare disturbances by the use of epinephrine during anesthesia. Meek and his associates<sup>41</sup> concluded from their experiments that cyclopropane affects the automatic tissue of the heart in dogs to a greater extent than ether or chloroform. They state in part:

"In the adrenalin controls A-V blocks were common and the ventricular rhythms were slow in nature. When the heart was under the influence of cyclopropane, however, the ventricular specialized tissue was so heightened in its irritability that when adrenalin reached it an automatic rate appeared that was dominant over the sinus. The ventricular tachycardias were almost always at the rate of 300 a minute."

They<sup>41</sup> also showed that the predisposing effect of cyclopropane for ventricular tachycardia seemed to be directly related to the concentration of the anesthetic agent. With epinephrine tachycardia developed in fewer animals under light anesthesia than under deep. Even more significant than the numerical occurrence of the tachycardia was the length to which it persisted. Under light cyclopropane, the tachycardia lasted less than half as long as under deep anesthesia.

The significance of these observations, however, is difficult to evaluate from a practical standpoint, in the opinion of Seevers and Waters,<sup>2</sup> since irregularities are a common clinical occurrence with all types of anesthesia including procaine blocks. In Kurtz's series,<sup>36</sup> of 109 cases with all agents, only 21 per cent failed to show some disturbance of cardiac rhythm.

Cyclopropane in anesthetic concentrations relaxes the peripheral blood vessels, according to Seevers and Waters,<sup>2</sup> and venous blood becomes arterialized even when the inspired oxygen is 21 per cent. Capillary bleeding seems to be increased,<sup>2</sup> according to Marshall,<sup>39</sup> this is due in part to the absence of compensatory sympathicotonia and hyperadrenia.

The blood pressure may rise during cyclopropane anesthesia, and this is believed to be due to the accompanying retention of carbon dioxide, anoxemia or pressor reflexes which rise from the sensory stimulation of light anesthesia rather than from the anesthetic agent per se, since if care is taken to eliminate these factors a rise is seldom seen. Rowbotham<sup>42</sup> found that systolic blood pressure was increased 10, 20 and 30 mm at the start of anesthesia and that this rise was followed by a rise in the diastolic, both rises in his opinion being proportional to the depth of anesthesia. Contrarily, he used anesthesia in a case of hypotension in which there was no change in the blood pressure.

Moffitt<sup>37</sup> noted lowering of blood pressure with nitrous oxide majors, cyclopropane minors and ethylene majors in the order of incidence. Sise<sup>10</sup> states that the blood pressure drops or rises slightly in cyclopropane anesthesia and Bogan<sup>43</sup> claimed a rise of blood pressure of from 10 to 20 mg.

Experimental and clinical evidence indicates that electrocardiographic change encountered during cyclopropane anesthesia is transient rather than permanent, but there are as yet no functional or pathologic studies determining definitely the absence of permanent effects. Tucker<sup>44</sup> reported one case of shock in a patient who had received 750 cc of cyclopropane. The patient recovered, but Tucker recommended watching closely for shock and poor operative risks. Moffitt<sup>37</sup> did not believe that there was any great difference in the circulatory depression seen in cyclopropane as compared with those following nitrous oxide ether anesthesia. As a matter of fact, he found shock more frequent in both nitrous oxide majors and ether majors than he did in cyclopropane majors. Although the early experimental work on dogs and man indicated that the heart rate is usually reduced below the resting level,<sup>45</sup> Waters does not believe that further work will confirm this finding.

In the opinion of Romberger,<sup>22</sup> untoward effects on the heart in the cardiovascular system should not occur under reasonably normal circumstances. Sanders<sup>46</sup> believes that cyclopropane is less dangerous to the heart than other agents, and Marshall postulates that apart from minor disturbances of rate and rhythm in deep anesthesia cyclopropane has little toxicity for the circulatory system, since he believes that the compensatory sympathicotonia and hyperadrenia of ether and chloroform are absent.

It can be definitely stated, however, that deep concentrations of cyclopropane are inexcusable, both because they are unnecessary and because they are potentially dangerous to cardiac tissue. The combination of epinephrine and other sympathotonic drugs or any drugs that increase the irregularities of the automatic tissue of the heart should be avoided. It is essential to watch the pulse carefully and continually during cyclopropane anesthesia, especially if anesthesia is deepened to the point of beginning respiratory depression.<sup>47</sup> Sise notes that high concentrations are toxic to the heart but that they should never be used clinically, while Waters warns that rapid induction should be avoided. Waters and his associates are continuing their studies of the effects of cyclopropane on the cardiovascular rhythm as well as of cardiac damage and other circulatory effects.

Robbins and Baxter<sup>48</sup> found in dogs that cardiac output was increased under surgical anesthesia and remained unchanged or was decreased under very deep anesthesia.

**Respiratory System.**—Cyclopropane is an anesthetic gas which has a characteristic, not unpleasant odor and which, according to Romberger<sup>22</sup> is practically nonirritating in concentrations less than 50 per cent used clinically.<sup>10</sup> The Imperial Chemical Industries, Ltd., brand is claimed by the Englishman Rowbotham<sup>42</sup> to be less pungent and more pleasant to breathe than the Ohio Chemical & Manufacturing Co. brand.

Waters<sup>30</sup> points out that the irritant property of ether vapor precludes the temptation to use high concentrations, while cyclopropane is devoid of that irritation. Because of this and the abundant oxygen present there is little to discourage the careless anesthetist from using too much of this potent anesthetic agent. Authorities differ as to whether laryngospasm is more frequent or less frequent with cyclopropane than with other anesthetic agents. The respiratory stimulation so commonly seen in the initial and lighter stages of ether anesthesia is absent in cyclopropane except when preliminary medication is also employed or there is accumulation of carbon dioxide in the closed system.<sup>22</sup> Other factors contributing to the ease with which this agent may be administered without indication of dangerous-

concentration is the smooth induction, which usually occurs without excitement, and the fact that it is essentially a respiratory depressant, especially when premedication is employed.

Waters<sup>30</sup> made a thorough study of the effect on the respiratory system and found that there was no stimulation during inhalation, slight depression during the first and second planes and very slight depression in the third plane down to the point at which respiratory arrest began to approach. In this respect it differs from all other anesthetic gases.<sup>10</sup> Even the increasing rate, which usually occurs with other agents just prior to respiratory arrest, is very slight or absent. The decrease in minute volume respiration is accompanied by an increase in the carbon dioxide content in the arterial blood<sup>30</sup> and the tissues.<sup>28</sup> Bourne has been reported to have suggested that the oxygen-rich atmosphere used with cyclopropane may be responsible for the retention of carbon dioxide by the muscles and other tissues and that this carbon dioxide toxicity may be responsible for the postoperative collapse seen occasionally with this anesthetic. In increasing concentrations to the point of respiratory arrest, it is seen that respiration invariably fails before circulation and, therefore, that recovery occurs readily if artificial respiration is instituted and the concentration diminished.

Moffitt<sup>3</sup> in his studies of various anesthetics noted the incidence of pharyngitis decreasing in the following order: ethylene majors, ethylene minors, nitrous oxide majors and cyclopropane majors, but on the other hand cough was most frequent in cyclopropane majors and ethylene majors. Pneumonias occurred most frequently in nitrous oxide majors, nausea in ethylene minors and emesis in ether majors, ether minors and ethylene majors in order. The early work reported on the lowered incidence of pulmonary complication in anesthesia with this agent by the Wisconsin workers has been confirmed by Bonham.<sup>50</sup> Knight and Urner<sup>51</sup> did not encounter any respiratory complications in thirty-two cases in which they used cyclopropane in a self-administering device for obstetric analgesia. However, pulmonary complications are not common in obstetric analgesia and anesthesia.

Mechling and Moffitt<sup>52</sup> found the incidence of pneumonia increased in the following order: spinal nitrous oxide, cyclopropane, ether and ethylene, for bronchitis and pharyngitis ethylene cyclopropane, nitrous oxide, spinal and ether.

The clinical anesthesia results in relatively slight salivation. Waters believes that it is much less than that obtained with ether and chloroform and more than that obtained with nitrous oxide and ethylene. Seevers and Waters note that little is known concerning the secretion of mucus resulting from these various anesthetic agents and that the mucus rather than the serous secretion is more troublesome during anesthesia.

Burford<sup>53</sup> reported an incidence of 0.97 per cent of pulmonary complications in his series of 1,333 administrations and noted that Taylor and his associates<sup>54</sup> reported an incidence of 0.95 per cent in a series of 5,889 administrations. Griffith<sup>55</sup> in a series of 300 cases, reported pulmonary complications of 0.67 per cent while Moffitt and Mechling<sup>50</sup> reported none in 315 cases.

Burford,<sup>53</sup> however, had a pulmonary complication incidence of 2.07 per cent in his 626 abdominal cases and Griffith<sup>55</sup> 1.8 per cent in 109 abdominal cases. Burford and Jones<sup>57</sup> reported four deaths due to massive atelectasis and discussed their possible cause—quiet respiration and high alveolar oxygen and prevention by the addition of helium to the anesthetic mixture. Griffith<sup>58</sup> reported a case of acute pulmonary edema following cyclopropane with recovery.

**Gastrointestinal Tract**—Raginsky and Bourne<sup>59</sup> found no liver injuries in dogs after repeated daily administrations for periods of one hour, as judged by the capacity to eliminate bromsulphalein and by histologic examination. Neither did cyclopropane have an adverse effect on the rate of recovery from hepatic injury produced by chloroform, as judged by the same criteria. These authors, according to Seevers and Waters, could find no evidence of additional hepatic injury to eclamptic patients who gave evidence of such injuries by retention of dye.

Peoples and Phatak<sup>60</sup> reported an increased tone of isolated rabbit jejunum when exposed to from 10 to 25 per cent cyclopropane in oxygen. Meek's associates Weisel, Youmans and Cassels<sup>61</sup> have found that both the circular contractions and propulsive phenomena are inhibited or arrested in normal dogs with Thyry or Thyry-Vella fistulas during deep cyclopropane anesthesia. Prompt return to normal or increased activity occurred when anesthesia was terminated. Peoples and Phatak<sup>60</sup> believed that these results indicated that there would probably be less postoperative intestinal stasis and distention in the clinical use of cyclopropane than there was with ether. Seevers<sup>62</sup> observed that the ten minute inhalation of 6 per cent cyclopropane inhibited hunger contractions in man without affecting gastric tone. These contractions returned in full strength when inhalation ceased and progressed to the usual tetanic contraction.

Waters reports that in a series of 10,638 cases, nausea and vomiting occurred in 56.5 per cent of the ether cases, 39 per cent of the cyclopropane cases, 33 per cent of the ethylene cases, and 23 per cent of the nitrous oxide cases.

Mechling and Moffitt<sup>52</sup> found the incidence of nausea and vomiting to decrease in the following order: ether, ethylene, cyclopropane, nitrous oxide and spinal anesthesia. Romberger<sup>2</sup> believed that cyclopropane-oxygen compares favorably with ethylene-oxygen as far as the incidence of postoperative nausea and vomiting are concerned. Gould<sup>63</sup> noted postoperative nausea.

Tucker,<sup>44</sup> Morgan,<sup>64</sup> Griffith<sup>65</sup>, Knight and Urner<sup>51</sup> and Romberger<sup>22</sup> noted that nausea and vomiting were lessened with cyclopropane, especially if there had been premedication, and that cyclopropane produces less nausea and vomiting than ether but more than nitrous oxide.

In the series of 10,638 cases referred to, distention occurred in 16% per cent of the 2,400 ether cases, 13 per cent of the 5,800 cyclopropane cases, 7 per cent of the 1,000 ethylene cases, and 3 per cent of the 1,300 nitrous oxide-oxygen cases. In this series nitrous oxide or ethylene were seldom used for abdominal operations or the incidence of distention with these agents would have been higher. Morgan<sup>64</sup> and Griffith<sup>65</sup> encountered less distention than with other agents.

**Genito Urinary Tract**—Burger<sup>16</sup> notes that the effect of cyclopropane on kidney function and bladder musculature remains to be studied, but Sanders and Fink<sup>40</sup> pointed out that Waters and Schmidt noted that the kidney output was occasionally depressed during cyclopropane anesthesia and that it was followed by a compensatory increase several hours later such as occurs with ether and ethylene. They<sup>40</sup> believed that bladder function was less affected, since fewer catheterizations were required following cyclopropane anesthesia. They<sup>40</sup> also believed that distention was reduced and diminished.

Waters gives the incidence of urinary retention in his series as 7.5 per cent of cyclopropane cases, 5.4 per cent of ether, 2 per cent of ethylene and 2.8 per cent of nitrous oxide. In general, however, he believes that retentions are not related to the anesthetic per se but rather to the type of operation performed. Mechling and Moffitt<sup>52</sup> found the incidence of reten-

tion to increase in the following order: spinal, cyclopropane, nitrous oxide, ethylene and ether. Nephritis occurred most frequently in nitrous oxide majors, ether majors and cyclopropane majors, in that order.<sup>87</sup>

**Central Nervous System**—Tucker<sup>44</sup> reported a few cases of headache with cyclopropane and one case in which there was no headache with ethylene. Knight and Urner<sup>41</sup> found no mental dulness following prolonged administrations. Challis<sup>66</sup> complained that headache was encountered in those occupying the amphitheater during cyclopropane anesthesia. Mechling and Moffitt<sup>52</sup> found that the incidence of headache decreased in the following order: spinal, cyclopropane, nitrous oxide, ethylene and ether. Griffith<sup>58</sup> reported a case of convulsions under cyclopropane and nupercaine, apparently due to an idiosyncrasy to the nupercaine.

**Other Pharmacologic Effects**—Henderson and Lucas noted but little rise in the blood sugar of cats and rabbits during cyclopropane anesthesia. Eversole<sup>38</sup> notes that there is a temporary slight rise in blood sugar but no change in the acid base balance. Henderson and Lucas found that there was little effect on the hydrogen ion concentration and carbon dioxide combining power of the blood. Seevers and Waters note that there is a 10 per cent rise in blood sugar. A 75 per cent elevation in blood phosphorus occurred. According to Seevers and Waters, Neff and Stiles<sup>6</sup> observed an 8 to 30 per cent rise in the blood sugar of twenty-five patients. Schmidt and Waters noted that the nonprotein nitrogen and carbon dioxide combining power of blood were not significantly affected in twenty-one clinical administrations. There was a constant lowering of carbon dioxide combining power by from 2 to 7 volumes per cent but no change in the nonprotein nitrogen. They did not observe any change in the carbon dioxide combining power of thirty controlled diabetic patients anesthetized with cyclopropane.

Taylor and Waters<sup>65</sup> found that cyclopropane like other agents—nitrous oxide, ethylene and ether—produced an absolute and relative increase of the leukocytes of peripheral blood which persisted several days after anesthesia. That this rise was not due to trauma was indicated by the fact that unoperated dogs show slight changes. No consistent changes in red cell volume or coagulation time were reported by Seevers and Waters.<sup>2</sup>

There is no evidence that cyclopropane undergoes any chemical alteration in the body or that it is isomerized to propylene<sup>28</sup> (see under impurities). There is no clear-cut histologic evidence of parenchymatous injury by cyclopropane, but the question is not settled, particularly in view of the evidence of functional alteration of cardiac automaticity.<sup>2</sup> Such a study is desirable, but in order to be convincing the evidence must be obtained on animals living under controlled dietary conditions.

#### CLINICAL ANESTHETIZATIONS

**Signs of Anesthesia**—One of the most important points to consider in the administration of cyclopropane is that it is not a respiratory stimulant. Of equal importance is the fact that the color of the patient cannot be used as an index of the plane or depth of anesthesia. It is Bonham's opinion<sup>50</sup> that the pulse gives the best index of the patient's condition and that either a marked slowing to 50 or a definite increase indicates overdosage. The signs of Guedel<sup>61</sup> are not applicable to anesthesia under cyclopropane. Romberger made a special study of the signs of the various planes of cyclopropane anesthesia. The first sign to observe according to his plan is the lid reflex. It gradually lessens during induction and becomes absent when the patient enters early sleep. This is the first plane of anesthesia and, according to Waters and Schmidt,<sup>70</sup> represents a concentration of about 74 per cent. Romberger's index for the second plane of anesthesia is the eyeball movement, which lessens as anesthesia develops and serves as an index of the depth of anesthesia during the second plane which, according to Schmidt and

Waters, occurs approximately at 131 per cent concentration. The third plane begins when the movement of the eyeball ceases and thereafter deep anesthesia is being approached rapidly and caution is necessary. The concentration at this point of the anesthesia ranges around 23.3 per cent, according to Schmidt and Waters. Anesthesia is maintained at the desired level—some where in the second plane—by cutting off the cyclopropane and continuing the oxygen until the depth is lessened. In deep anesthesia—third plane—the respiratory rate and amplitude is the only safe sign to follow, according to Romberger,<sup>7</sup> and it is quick. To maintain anesthesia it may be necessary to supply a trickle of cyclopropane (from 25 to 100 cc per minute) for from six to ten minutes to compensate for leakage, diffusion and usage. There is no cyanosis with cyclopropane oxygen anesthesia, and it should never be permitted to ensue and hence is not a practical sign of the depth of anesthesia. When it does occur in cyclopropane anesthesia it indicates anoxemia with excessive carbon dioxide.

Passage through the first two stages described is usually very rapid and, as noted, the ordinary signs of anesthesia are missing. There is always a potential danger unless proper caution is used of encountering overdosage, which along with high concentrations and accumulated effects produces a fall in the rate of respiration and a lessening in tidal exchange. Both of these are indicated by the excursions of a breathing bag, and it is important to note that they may occur even in the presence of a very pink color of the patient.

#### ADMINISTRATION METHODS

Of primary consideration in the administration of this anesthetic is the fact that it is an explosive agent. For this as well as for other reasons the closed technic is preferable. Waters has stated that the carbon dioxide absorption setup attached to a completely closed machine was the best safeguard against explosion, but that, nevertheless, cyclopropane must always be considered to have the same potential danger as ether and ethylene. Bonham,<sup>50</sup> using this technic, starts with a bag two thirds full of oxygen and permits a flow of cyclopropane and oxygen, each 500 cc per minute for from three to five minutes. He then temporarily discontinues the cyclopropane, allowing the patient to breathe the mixture in the bag. He adds it gradually in small amounts as needed. Griffith<sup>58</sup> fills the bag with oxygen and then adds cyclopropane at the rate of from 500 to 600 cc per minute until anesthesia is established and then maintains it at the required plane with a mixture of oxygen and cyclopropane.

Romberger fills the bag partly or completely with oxygen and then permits the patient to breathe into the closed circuit, at which time a small stream of cyclopropane is started, ranging from 250 to 750 cc per minute. Anesthesia is maintained at the desired level, as indicated by the signs and not by estimates of percentages,<sup>28</sup> by cutting off the cyclopropane and continuing the oxygen, supplying as necessary a trickle of cyclopropane from 25 to 100 cc per minute for from six to ten minutes to compensate for leakage, diffusion and usage.

Sise, Woodbridge and Eversole fill the breathing bag with sufficient oxygen for tidal breathing, place a mask on the face and increase the flow of anesthetic to from 200 to 300 cc per minute until the loss of the lid reflex, when it is reduced to one third this amount or discontinued, the remainder of anesthesia consists of basal oxygen with occasional additions of cyclopropane necessary to maintain anesthesia.

#### PREMEDICATION

The addition of various agents used in premedication must be carefully considered when cyclopropane anesthesia is to be employed. The principal reason for precautionary use of such agents is the fact that the gas is not a respiratory stimulant. Sise and his co-workers<sup>10</sup> note that the signs of anesthesia under cyclopropane are much clearer without premedication and are difficult to determine, important as they are, if much premedication has been administered. It has been noted<sup>7</sup> that if premedication is employed lower concentrations of the gas produce satisfactory anesthesia in man. It has been stated that premedication is contraindicated with cyclopropane because it is not a respiratory stimulant, and such medication should be limited to allaying apprehension.

70 Waters R. M. and Schmidt E. R. Cyclopropane Anesthesia Postoperative Morbidity in 2200 Cases. *Anesth. & Analg.* 14: 1 (Jan-Feb) 1935.

Griffith<sup>67</sup> has used 3 grains (0.2 Gm) of pentobarbital sodium and  $\frac{1}{10}$  grain (0.0004 Gm) of atropine preoperatively but has avoided the use of morphine. Rowbotham<sup>46</sup> who incidentally encountered many difficulties which at least in part were due to overuse of premedication employed omopon (prantopium hydrochloride)  $\frac{1}{50}$  grain (0.002 Gm) per stone<sup>1</sup> or pentobarbital sodium intravenously or evipal in addition to prantopium hydrochloride and scopolamine. Mechling and Moffitt<sup>47</sup> recommend premedication with scopolamine but not with the opiates or atropine while Marshall<sup>39</sup> recommends atropine or scopolamine to restrict salivation.

Sanders and Fink<sup>48</sup> believe that premedication is contraindicated as a general rule but nevertheless use one-sixth grain (0.01 Gm) of pantopon (prantopium hydrochloride) two hours preoperatively and repeat the dose with the addition of  $\frac{1}{4}$  grain of atropine sulfate one hour preoperatively. Bonham<sup>9</sup> believes that premedication should be employed cautiously and used  $\frac{1}{2}$  grains (0.1 Gm) of pentobarbital sodium one and one-half hours preoperatively and pantopon, one third grain (0.02 Gm) with atropine,  $\frac{1}{4}$  grain one-half hour preoperatively. Seevers and Waters determined that the use of ordinary doses of morphine preoperatively reduced by from 10 to 12 per cent the amount of cyclopropane required to effect a given level of anesthesia.

Sise<sup>8</sup> believes that premedication is an individual problem. He uses 3 grains of pentobarbital sodium one and one-half hours preoperatively and the usual one eighth grain (0.008 Gm) of morphine sulfate and from  $\frac{1}{500}$  to  $\frac{1}{2}$  grain (0.3 to 0.25 mg) of scopolamine subcutaneously forty-five minutes preoperatively. He believes that premedication is especially valuable in "activated hyperthyroidism," in which he generally employs  $4\frac{1}{2}$  grains (0.3 Gm) of pentobarbital, one-fourth grain (0.016 Gm) of morphine sulfate and  $\frac{1}{500}$  grain of scopolamine. On the other hand, in "apathetic hyperthyroidism" he used less than the usual amount of premedication, i. e., one-tenth grain (0.006 Gm) of morphine sulfate.

#### INDUCTION, MAINTENANCE AND RECOVERY

Induction with cyclopropane is pleasant, and this fact becomes one more reason for its careful administration. Patients who have been given various anesthetic agents have expressed a preference for cyclopropane. Anesthesia generally ensues in from one to two minutes and, as already noted, premedication has the effect of flattening out each stage of anesthesia.<sup>22</sup> There is generally no choking<sup>42</sup> and seldom any struggling—Bogan's series showed excitement in only 3 per cent.<sup>43</sup> Nevertheless, as Marshall pointed out, it is necessary to allow sufficient time to elapse before surgical procedures are instituted for otherwise troublesome and sometimes persistent laryngeal spasm occurs, necessitating the introduction of a Magill endotracheal tube for its correction and control.

It is noted under the general discussion of administration methods that, once established, cyclopropane anesthesia is not difficult to maintain. In fact it is sometimes only necessary to replace quantities lost or absorbed. At any rate the addition of small amounts of cyclopropane to the breathing mixture from time to time, as indicated by the condition of the patient and the plane of anesthesia produces a satisfactory maintenance. Sise, Woodbridge and Eversole<sup>10</sup> believe that 4 liters of cyclopropane an hour should produce adequate anesthesia for the average case. Marshall<sup>39</sup> noted that 4 or at most 8 liters of cyclopropane should suffice and that oxygen is used at the rate of about 20 liters an hour. Marshall pointed out the advantages of the closed circuit method—definite concentrations of cyclopropane and oxygen were presented to the patient because oxygen is supplied continuously in sufficient amounts to meet the patient's basal requirements, because a carbon dioxide soda-lime absorption device can be thrown in or out of the circuit at will, and finally because the enclosed gases so rapidly become saturated with water vapor that the danger of ignition is reduced and irritation diminished.

Recovery from cyclopropane anesthesia is relatively rapid in spite of the fact that desaturation takes place over a period of several hours, as has been noted. Mechling and Moffitt believe that these patients as a rule are a little slower in recovering than are patients to whom other gases have been administered alone, not in combination with another agent.

#### RELAXATION AND OOZING

There has been some difficulty with cyclopropane in connection with the degree of abdominal relaxation obtainable at low anesthetic levels. Those who have had the most experience with the agent, however, have not found it necessary to add other ingredients to the anesthetic mixture to obtain satisfactory relaxation. In Römberger's opinion<sup>22</sup> relaxation is less satisfactory than with ether but more satisfactory than with ethylene or nitrous oxide. Marshall<sup>39</sup> believed that relaxation was usually adequate. Sanders and Fink<sup>48</sup> went so far as to state that muscular relaxation was in many cases even better than with ether. It is granted that third plane anesthesia may be required to effect complete abdominal relaxation, but it must be remembered that third plane anesthesia occurs at a concentration of approximately 23 per cent, which still leaves more than 70 per cent of oxygen in the anesthetic mixture. In dogs it was obtainable in concentrations of from 22 to 24 per cent.<sup>11</sup> Griffith was able to obtain adequate relaxation without the addition of ether in 90 per cent of his cases.

Griffith<sup>67</sup> notes that surgeons observed an increased capillary oozing but believes it is more apparent than real because of the bright red color of the blood under cyclopropane anesthesia. He believes also that it is superficial rather than deep because it continues only as long as the tissue is handled.

#### GAS MACHINES AND SPECIAL DEVICES

Only the most modernly constructed or adapted gas oxygen machines should be used in cyclopropane anesthesia.<sup>22</sup> The anesthetist then has the advantage of having two or three gas anesthetics available plus oxygen plus carbon dioxide and an ether vaporizer, as well as a closed circuit or breathing device with a soda-lime attachment. Of considerable help is the use of exceedingly fine flow meters so that rates as low as 100 cc or less may be accurately registered.<sup>72</sup> Leech<sup>73</sup> described a special pharyngeal bulb gas way for use with this system.

Knight and Urner<sup>41</sup> described a special device for self administration of cyclopropane in obstetrical analgesia, which consists of a mask, an inhalation bag, a one-way exhalation valve and a two gallon supply bag three-fourths full of cyclopropane, a gas regulator and a pressure bulb—all attached by rubber tubing. With this apparatus no gas is given until the bulb is pressed at the onset of pain, when it is rapidly operated and the patient takes deep breaths until relief is obtained. Deep analgesia or early anesthesia supervenes and prevents further operation of the bulb and hence there is automatic cessation of cyclopropane. The patient recovers rapidly and waits in full consciousness for the next pain. The procedure is generally not instituted until the pains have become severe and the cervix dilated about 4 cm. It is said to aid full contraction, and it is thought that with its use labor progresses more rapidly. It is necessary to have the room well ventilated, and to be certain that there is no pressure on the reservoir, which is never left attached to a tank of cyclopropane.

#### TYPES OF CASES

Bogan<sup>43</sup> reported on the use of cyclopropane in 300 surgical anesthetics in patients ranging in age from 5 to 84 years. He believed that the high oxygen concentration was especially useful in the young and old. In this series, 145 patients were given cyclopropane, sixty cyclopropane and ether and 100 cyclopropane and avertin with amylene hydrate with either morphine or pentobarbital sodium.

Griffith<sup>65</sup> reported the use of cyclopropane in 1,108 cases of which 592 were abdominal procedures. Tucker<sup>44</sup> employed cyclopropane in 139 major operations, including the case of one 6 year old child given six satisfactory cyclopropane anesthetics in connection with an appendectomy complicated by pleurisy and peritonitis. One of his patients was desperately ill with diabetes and required amputation of the leg, with blood pressure of 240 systolic 100 diastolic. The anesthesia was satisfactory, but death ensued from a cerebral hemorrhage.

Burford<sup>74</sup> employed cyclopropane in 475 cases and obtained satisfactory anesthesia in "desperate surgical risks" without

<sup>71</sup> One stone equals 14 pounds (6.4 Kg)

death or accidents Morgan,<sup>64</sup> Griffith and others analyzed 100 cases of cesarean section under cyclopropane Bonham<sup>60</sup> reported its use in 732 cases Griffith used it in patients whose ages ranged from 10 days to 85 years

#### OBSTETRICS, THYROID SURGERY AND THORACIC SURGERY

Knight discussed the use of cyclopropane in obstetrics—by filling the bag with a 10 per cent mixture and with each pain instructing the patient to exhale and then take two inhalations of the mixture while bearing down He believes that the anesthetic does not retard the pains, although it abolishes them and probably hastens delivery For episiotomy the gas flow is increased to about 10 gallons an hour for three or four inhalations The same mixture is used for the delivery proper and the Crede expression of the placenta In many cases relaxation was sufficient to preclude episiotomy and to aid instrumental delivery He does not believe that oozing is increased and is certain that uterine bleeding is not increased Morgan believes that there is less blood lost from the uterus in cyclopropane anesthesia and did not encounter any maternal deaths He compared these results with a series of ethylene-ether anesthetics in which there were two deaths in seven cases of dynamic ileus Bonham<sup>60</sup> believes that the use of cyclopropane is especially indicated in obstetrics because of the marked contractions of the uterus which occur under cyclopropane anesthesia

Sise<sup>9</sup> considers cyclopropane useful in meeting the problems of thyroid surgery anesthesia Goetsch<sup>75</sup> compared cyclopropane with other anesthetics in a series of thyroidectomies in which nitrous oxide was used in thirty-three cases, cyclopropane in fourteen cases, ethylene in eight cases and cyclopropane and procaine hydrochloride in one case In spite of the fact that the cyclopropane series included complications consisting of one pulmonary embolism with infarction, one typical shock, one moderately severe shock and one fatal thyroid crisis, the author believes that cyclopropane will replace nitrous oxide-ether for thyroidectomy It is reported that he has stated that he encountered 50 per cent arrhythmias during thyroidectomy with cyclopropane unless nitrous oxide was combined with it<sup>76</sup> He warned about the danger of hyperventilation and noted that the apnea, which is sometimes seen, may be due to hyperoxidation and suggested the use of carbon dioxide and artificial respiration when apnea occurred

Eversole and Overholt<sup>77</sup> discuss the difficulties of anesthesia in thoracic procedures The principal difficulties encountered, of course, arise from the fact that the pathologic condition exists in the organs of the respiratory system, which are also employed for anesthesia Specifically, the difficulties are 1 The absorption area is reduced and abnormal amounts of mucus and secretions are formed 2 There is an increased tendency to cough and the good lung, if any, is in a dependent position and may become contaminated during anesthesia and surgery Pneumothorax presents the additional problem of embarrassing both the respiratory and the circulatory system, and it is, therefore, especially important to employ the closed system of anesthesia because of the control of interpulmonary pressure, which is obtainable in no other way Using an anesthetic mixture of 20 per cent cyclopropane and 80 per cent oxygen these authors found the mixture to be a fairly satisfactory anesthetic agent in these cases Little absorptive area is necessary, in fact, they believe that one quarter of the area of the normal lung is adequate for maintaining quiet, shallow respirations under cyclopropane anesthesia Using other agents, they encountered anoxemia, cyanosis, accumulation of carbon dioxide, stimulation of the respiratory movements and rising pulse Roventine<sup>78</sup> also reported the use of cyclopropane in thoracic surgery He pointed out that because it is not a respiratory stimulant the excursions of the chest are lessened considerably He did not encounter laryngeal spasm and stated that its advantages include rapid induction, abundant oxygen, abol-

ishment of laryngeal reflexes and ease of endotracheal intubation It has no disagreeable odor, is nonirritant and hence does not produce mucus Roventine's experience comprises 4,000 clinical cases, but this report refers to 160 cases of thoracic surgery There was an 8 per cent mortality one case during operation, one during the first day, five more during the first week and six more than five weeks later With the exception of the first two cases, which were circulatory in nature, they all presented postoperatively pathologic changes in the lungs, although it is granted that poor anesthetic technique would certainly increase the morbidity in such cases as these

#### HOMOLOGUES OF CYCLOPROPANE

Henderson and MacDonald<sup>79</sup> experimented with the methyl cyclopropanes—1,2 dimethyl and 1,2,3 trimethyl—and found them unsuitable for anesthesia, producing more cardiac irregularities than cyclopropane, producing low blood pressure and deleterious effects on cardiac contractility as well as more marked tonic effects

Lott, Christiansen and Shackell<sup>80</sup> found effective concentrations and lethal concentrations about equal for 1 methyl cyclopropane and cyclopropane but found more undesirable side effects with the methyl compound

#### SUMMARY

A brief review and analysis of this material follows

From the chemical and physical properties it is seen that cyclopropane has the same potential danger of explosibility as the more commonly used ethyl ether There are several brands available, one of which is made by a different process than the others There is the possibility that there may be impurities present in the commercial brands There appears to be an unusual effect on the heart, since arrhythmias have been encountered that are not ordinarily seen with ether anesthesia Experience has indicated that epinephrine or other sympathomimetic amines should not be administered during anesthesia with cyclopropane For this reason, as well as because the ordinary signs of anesthesia are not useful, it is necessary to watch the pulse very closely during administration of cyclopropane The gas has a not unpleasant odor and is not ordinarily considered to be irritant The question of whether laryngospasm is more frequent with other agents remains to be settled The incidence of pulmonary complications seems to be no greater than or not as great as the incidence following ether anesthesia In anesthetic concentrations there does not seem to be a deleterious effect on the liver The kidney output is similar to that seen with ether and ethylene Headache may occur more often than with ether anesthetics The other pharmacologic effects of the drug are discussed The signs of the various stages of anesthesia are described It is important to note that it is recommended that no one attempt to administer this gas who is not thoroughly familiar with its properties and with the signs that are available to indicate the depth of anesthesia, these differ from the signs for other anesthetic agents Many authorities believe it preferable to use the closed technique and, because the respiratory center is not stimulated, premedication that affects the respiratory rate should be used with caution Details of induction, maintenance and recovery are given, relaxation and oozing are discussed and the use of various types of gas machines are mentioned There seems to be no special type of case in which cyclopropane should be avoided, with the possible exception of certain cardiac conditions, because of the tendency of the agent to produce arrhythmias Its usefulness in obstetrics both as an anesthetic and for analgesia and in thyroid and thoracic surgery is described Brief mention is made of the homologues of cyclopropane

This review indicates that cyclopropane is a suitable anesthetic agent when used cautiously by those fully informed of its properties, potential dangers and signs which indicate the stages of anesthesia obtained with this agent

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C. BING, Secretary

#### CLAPP'S STRAINED MIXED GREENS

**Manufacturer**—Harold H. Clapp, Inc., Rochester, N. Y.

**Description**—Canned strained mixed greens containing equal proportions of kale, lettuce and Swiss chard. Slightly seasoned with salt.

**Manufacture**—The fresh kale, lettuce and chard are inspected, sorted, mechanically cleaned and washed. The washed greens are softened by live steam in the absence of air and strained. Salt is added and the strained greens are filled into cans, sealed and heat processed.

**Analysis** (submitted by manufacturer)—Moisture 93.8%, total solids 6.2%, ash 0.8%, sodium chloride 0.12%, fat (ether extract) 0.4%, protein (N  $\times$  6.25) 1.6%, reducing sugars (as invert sugar) 0.3%, sucrose (copper reduction method) 0.2%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 2.9%, calcium (Ca) 0.06%, phosphorus (P) 0.04%, iron (Fe) 0.001%.

**Calories**—0.22 per gram, 6.2 per ounce.

**Vitamins**—No evidence has been provided the Council as to the vitamin content of this product. The method of preparation and processing is designed to retain the natural vitamin values to the highest degree consistent with adequate and safe heating processes. Contact of the product with air during processing is avoided as far as possible.

#### CELLU BRAND PRUNE PLUM JUICE

**Distributor**—Chicago Dietetic Supply House, Inc., Chicago.

**Description**—Canned juice expressed from fresh prune plums packed without added sugar.

**Manufacture**—Fresh Italian tree-ripened prune plums on which no toxic spray materials have been used are sorted, washed, pitted and preheated. The pulp is pressed through a strong special mesh cloth and the resulting juice is filled into cans, sealed and heat processed.

**Analysis** (submitted by distributor)—Moisture 85.8%, total solids 14.2%, ash 0.3%, fat (ether extract) 0.5%, protein (N  $\times$  6.25) 0.3%, crude fiber 0.1%, carbohydrates other than crude fiber (by difference) 13.0%, invert sugar 6.9%, sucrose 3.7%.

**Calories**—0.6 per gram, 17 per ounce.

#### CALIFORNIA FRESH FLAVOR BRAND KADOTA FIGS FANCY QUALITY

**Manufacturer**—Beckwith Packing Corporation, Turlock, Calif.

**Description**—Canned Kadota figs, packed in syrup containing a mixture of sucrose and corn sugar, with added lemon juice and salt.

**Manufacture**—Ripe Kadota figs are hand sorted, mechanically graded for size, and blanched with steam and light hot water sprays. Cans are filled with fruit and syrup containing a mixture of sucrose and corn sugar, with added lemon juice and salt, preheated, sealed and heat processed. The fruit is sprayed with calcium sulfate, the last application being made not later than fifteen days before the fruit is gathered. According to the information submitted by the manufacturer, the blanching process, which draws the sap from the skin of the fruit, reducing the thickness of the outer portion, is adequate to remove any spray residue which might remain on the fresh fruit.

**Analysis** (submitted by manufacturer)—Moisture 67.2%, total solids 32.8%, ash 0.5%, fat (ether extract) 0.1%, protein (N  $\times$  6.25) 0.5%, total sugars as invert sugar 28.8%, crude fiber 0.6%, carbohydrates other than crude fiber (by difference) 31.0%, acidity (as anhydrous citric acid) 0.1%.

**Calories**—1.27 per gram, 36 per ounce.

#### W. N. CLARK BRAND TOMATO JUICE

**Manufacturer**—W. N. Clark Company, Rochester, N. Y.

**Description**—Canned tomato juice, seasoned with salt.

**Manufacture**—Fully ripe tomatoes are inspected, washed, again inspected, scalded, mechanically sliced, and preheated in an atmosphere of steam. The juice is extracted, seasoned with salt, heated to 85 C and automatically filled into cans which are sealed and heat processed.

**Analysis** (submitted by manufacturer)—Moisture 93.1%, total solids 6.9%, ash 1.1%, sodium chloride 0.6%, fat (ether extract) trace, protein (N  $\times$  6.25) 1.0%, reducing sugars before inversion, as dextrose 3.2%, reducing sugars after inversion, as dextrose 3.1%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 4.2%, titratable acidity as citric acid 0.4%.

**Calories**—0.2 per gram, 6 per ounce.

**Vitamins**—Chemical titration shows an average of 0.156 mg of ascorbic acid (3.12 international units of vitamin C) per cubic centimeter, 92 international units of vitamin C per fluidounce.

#### CRADLE BABY BRAND STRAINED AND SEEDLESS FIG JAM

**Manufacturer**—Glaser, Crandell Company, Chicago.

**Description**—Canned strained fig jam sweetened with sucrose. The jam may contain small amounts of added acid and/or pectin.

**Manufacture**—Dried California figs are washed, softened in sufficient warm water to cover the fruit and sieved. Sugar is added (and pectin and acid if needed to obtain the desired consistency) the batch is mixed and the mixture concentrated under vacuum at 60 C to not less than 68 per cent soluble solids. Glass jars are automatically filled and are sealed in a high temperature steam vapor chamber.

**Analysis** (submitted by manufacturer)—Moisture 25.5%, total solids 74.5%, water-insoluble solids 1.5%, water-soluble solids 73.0%, ash 0.6%, protein (N  $\times$  6.25) 0.8%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 73.0%, acidity 0.2%.

**Calories**—2.95 per gram, 84 per ounce.

#### KAFFEE HAG DECAFFEINATED COFFEE

**Manufacturer**—General Foods Corporation, New York.

**Description**—A blend of selected roasted coffee from which almost all the caffeine has been removed.

**Manufacture**—Green coffee is cleaned, steamed and the caffeine extracted with trichloroethylene, which is removed by steam distillation. The different coffees are blended in proportions designed to produce a standard beverage, roasted and automatically packed under vacuum in tins. The manufacturer states that each batch is tested to insure at least 97 per cent removal of caffeine.

**Analysis** (submitted by manufacturer)—Moisture 1.6%, water-soluble solids 22.1%, ash 4.2%, fat (petroleum ether extract) 16.9%, protein (N  $\times$  6.25) 12.1%, caffeine 0.03%, crude fiber 11.5%, tannins 3.3%, carbohydrates other than crude fiber (by difference) 53.7%.

#### MRS. PALEY'S BABY FOOD—STRAINED BEETS

**Manufacturer**—Paley-Sachs Food Company, Houston, Texas.

**Description**—Canned, cooked sieved beets slightly seasoned with salt.

**Manufacture**—Fresh beets are washed, pressure cooked until just soft enough to sieve, cooled in dilute salt solution, peeled, sieved, filled into glass jars, vacuum sealed and heat processed.

**Analysis** (submitted by manufacturer)—Moisture 91.6%, total solids 8.4%, ash 0.6%, fat (ether extract) 0.1%, protein (N  $\times$  6.25) 1.2%, reducing sugars as dextrose—trace, sucrose 3.7%, crude fiber 0.8%, total carbohydrates other than crude fiber (by difference) 5.7%, calcium (Ca) 0.024%, phosphorus (P) 0.032%, iron (Fe) 0.004%.

**Calories**—0.3 per gram, 9 per ounce.

## STERILIZATION OF AIR IN THE OPERATING ROOM

Modern atraumatic aseptic technic in the operating room has almost eliminated infection of wounds in clean cases. However, the introduction of major surgical procedures involving exposure of large raw areas for a long time has again raised the problem of occasional infection. Recently Hart<sup>1</sup> of the Duke University School of Medicine has reported studies during the past five years of efforts to eliminate the occasional sporadic operating room infection. After carefully checking all possible sources of infection, Hart concludes that the least controlled source of infection was air-borne bacteria. Most of the infections were caused by *Staphylococcus aureus-haemolyticus*. The organisms entered the wound from the air rather than from the skin of the patient. The air was contaminated by the operating room personnel and patients. All supplies and all procedures in the operating room technic were checked by the culture method and were found to be satisfactory except for the air, which was heavily contaminated with *Staphylococcus aureus-haemolyticus*. The personnel of the operating room and the general population were found at times to have *Staphylococcus aureus* in the nose and throat in as high as 78 per cent of the cases. A reduction of from 60 to 80 per cent was accomplished by reducing the number of persons in the operating room to the minimum, insistence on masks worn over the nose and mouth at all times, and elimination from the operating room of all persistent carriers of *Staphylococcus aureus* or of *Streptococcus*. The rooms were painted frequently and washed daily with an antiseptic solution. By forced ventilation the contaminated air was replaced by clean, washed air taken from above the roof. Despite these measures the number of organisms in the air was not reduced sufficiently to eliminate all infections. In every case of infection in which cultures of the air had been taken the organism cultured

from the wound was identical with the one cultured from the air during the operation.

The bacteriologic studies carried on daily convinced the author that the most important source of wound infection was not the bacteria present in the skin but the organisms eliminated from the noses and throats of the operating room personnel. The wearing of thick gauze masks was not apparently an adequate protection against this source of contamination. To eliminate this source the author turned to irradiation of the air. The problem consisted of designing a source of radiant energy which would provide a sufficiently high level of bactericidal radiation to destroy the bacteria without, at the same time, injuring the patient. The Westinghouse Lamp Company, at the request of the author, designed and constructed a special radiant energy apparatus which answers the requirements. An operating room was equipped with eight of these lamps, each 30 inches long. Two blond volunteers from among the students were exposed to radiation from these tubes for eighty minutes and received only a slight reddening of the exposed area, which disappeared within twenty-four hours. The author found that it was possible with eight tubes operating to kill a lightly sprayed culture of *Staphylococcus aureus-haemolyticus* on blood agar plates within sixty seconds or a heavily sprayed culture within less than five minutes. Practically all organisms exposed to the radiation from these tubes at a distance of 8 feet from the center of the cluster were killed within less than ten minutes, and at a distance of 10 feet within less than thirty minutes. In the corners of the room, 13 feet from the center of the cluster and 11 feet from the nearest tube, the number of viable organisms falling out of the air was reduced from 60 to 90 per cent. The air of the entire room could not be completely sterilized within one hour with only eight tubes and, when they were turned off, recontamination quickly occurred if people were present.

In a series of 132 individual stages of extrapleural thoracoplasties on fifty-nine patients performed in a field of air sterilized by means of bactericidal radiant energy, Hart<sup>2</sup> was able to report a lowering to one half of mortality due to infected wounds. There was an incidence of 3.8 per cent of skin infections as compared with 33 per cent in a previous series of 100 similar operations. The incidence of postoperative elevation of temperature was lowered so that more than two thirds of the patients did not have more than two recorded elevations above 38 C (100.4 F) as compared to one third of the patients without radiation who fell in this group. The wound healing has been more rapid and with less reaction when reopened for the second and third stages of thoracoplasty than in those cases in which radiation was not used. In practically all

<sup>2</sup> Hart Deryl. Sterilization of the Air in the Operating Room with Bactericidal Radiation. Comparative Analysis of 132 Individual Stages of Extrapleural Thoracoplasties Performed With Radiation and 110 Stages Performed Without Radiation. J Thoracic Surg 7: 525 (June) 1938.

cases the postoperative pain has been less and convalescence has been more rapid.

In a later report<sup>3</sup> the author presents an analysis of the results obtained in 456 clean primary incisions and eighty-six reopened clean incisions of more than 800 operations performed in the field of bactericidal irradiation. The operations were gastric or intestinal resections, cholecystectomies, mastectomies, appendectomies and amputations of gangrenous extremities. The analysis reveals that postoperative infections have been reduced more than 85 per cent. The occasional death anticipated from infection of a wound did not occur. The number of patients with postoperative temperature above 38 C has been reduced in thoracoplastics from 68 to 30 per cent, in radical mastectomies from 46 to 34 per cent and in inguinal herniorrhaphies from 36 to 22 per cent. The number of patients with a temperature above 37.5 C (99.2 F) for more than four days after operation has been decreased in thoracoplastics from 78 to 22 per cent, in radical mastectomies from 54 to 21 per cent and in inguinal herniorrhaphies from 46 to 14 per cent. There has also been noted a more rapid wound healing, a lessened systemic reaction and a shortened convalescence.

The bacteriologic studies carried out by Hart and his co-workers as well as the practical results obtained, seem to establish that air is an important source of contamination in every operative wound. They demonstrated further that sterilization of the air in the operating room can be accomplished by bactericidal irradiation. The method of bactericidal air irradiation may prove to be an important addition to efforts for eliminating infections of wounds in clean primary incisions.

## SECONDARY ANTIGENS IN RHEUMATIC FEVER

The demonstration of secondary antigens and antibodies in rheumatic fever recently reported by Coburn and Pauli<sup>1</sup> of Columbia University is clinical confirmation of a speculative hypothesis proposed a decade or more ago by immunologists.<sup>2</sup> If confirmed, this renaissance of the speculative theory of secondary anaphylaxis and immunity may lead to practical diagnostic and therapeutic methods in numerous infectious diseases.

The New York clinicians picture the evolution of rheumatic attacks in three distinct phases. Phase 1 is an acute pharyngeal infection usually of not more than three days' duration, hemolytic streptococci being the causative agent. This is followed by an afebrile, symptom-free period (phase 2) commonly lasting about fourteen days. Phase 3, the period of acute rheumatic symptoms, often shows one or more cycles of activity.

From then point of view the second period (phase 2) is the crucial stage in the genesis of rheumatic symptoms. Only one serologic abnormality has been definitely established during this period, a diminution in serum complement.<sup>3</sup> A still further reduction in complement titer takes place during the acute attack (phase 3). Since decreases in serum complement are known to take place when antigen and antibody coexist in the circulation, Coburn and Pauli postulate the existence of a phase 2, prerheumatic antigen, reacting with a phase 3 antibody as a cause of this complement "deviation."

To test this hypothesis, blood samples were taken at least once a week from rheumatic subjects recovering from hemolytic streptococcus pharyngitis. The resulting serums were preserved with merthiolate, stored at 5 C and afterward cleared by high speed centrifugation or by Chamberland filtration. 0.1 cc of the presumptive antibody-containing serum (phase 3) was layered over 0.1 cc of the presumptive antigen serum (phase 2) and flocculation reactions were recorded after ten minutes at room temperature, after two hours at 37 C and at the end of twenty-four hours at 5 C. The following scale of precipitin reaction was adopted: "cloudy whirl" (+), "small flakes or granules, supernatant clear" (++) and "large flakes" (+++).

Serums taken by the New York clinicians at the height of the rheumatic attack (phase 3) almost invariably showed definite precipitates (++) with the prerheumatic serums (phase 2) of the same individual. No reactions were noted between phase 1 and phase 2 serums or between phase 1 and phase 3 serums, nor would two phase 2 serums or two phase 3 serums from the same individual react with each other. A mixture of phase 2 and phase 3 serums was necessary to demonstrate the hypothetic antigen-antibody reaction.

Cross reactions of varying intensity were obtained between phase 3 and late phase 2 serums of different patients, the intensity of the reaction varying with the severity of the rheumatic attack. One patient with rapidly fatal fulminating rheumatism, for example, gave +++ reactions with the six heterologous phase 2 serums tested.

The controls included the serums of patients who had recovered from hemolytic streptococcus pharyngitis without subsequent development of rheumatism. Thirty-seven of the forty-seven control tests thus made were negative. As further controls it was shown that normal human serum and serums taken during nonrheumatic fevers were also consistently negative when layered over either phase 2 or phase 3 rheumatic serum.

An attempt was made to determine the nature of the presumptive phase 2 prerheumatic antigen by a study of control reactions with streptococcus antigens isolated from the same patient during the initial pharyngitis. Group specific carbohydrates, nucleoproteins and

<sup>1</sup> Coburn Alvin F and Pauli Ruth H. *J Exper Med* 69: 143 (Jan.) 1939.

<sup>2</sup> Manwaring W H, Marino H D, McCleave T C and Boone T H. *J Immunol* 13: 319 (May) 1927.

<sup>3</sup> Veil W H and Buchholz Bruno. *Klin Wchnschr* 11: 2019 (Dec 3) 1932. Coburn A F. *Lancet* 2: 1025 (Oct. 31) 1936.

"M-substance" were prepared from these autogenous streptococci. Mild precipitin reactions were obtained with one or more of these fractions plus phase 3 serum. These reactions, however, were not parallel with reactions to the patient's own phase 2 serum. Absorption of the phase 3 antibodies with the streptococcus antigens led to a complete removal of the streptococcus precipitins with little or no reduction in anti-phase 2 rheumatic titer. Tests with specific antistreptococcus antibodies of both human and veterinary origin were also negative.

The conclusion seems inevitable that the hypothetical phase 2 prerheumatic antigen is not a streptococcus product or an anti-streptococcus albumin or globulin. This seems to narrow the possibilities to the assumption that the phase 2 prerheumatic antigen is some secondary colloidal product arising from the primary reaction of hemolytic streptococci on pharyngeal tissue. Denatured cartilaginous material, for example, might be conceived as the source of this secondary antigen. A heterophil anticartilaginous antibody, although purely hypothetical, might be the basis for a plausible "inverse anaphylactic" theory of acute rheumatism.

While the possibility was borne in mind by the Columbia investigators that phase 2-phase 3 flocculation may not be due to a specific antigen-antibody reaction, the theory suggested or implied by their data is a stimulating working hypothesis for future serologic and biochemical research. The historical theory of secondary antigens and antibodies is presumably also applicable to numerous other microbial infections. The possibilities of using phase 3 rheumatic serum therapeutically or as a diagnostic agent (cutaneous test) have not yet been tested.

## Current Comment

### TRICHINOSIS IN THE UNITED STATES

The recent evidence from necropsies that 36 per cent of the inhabitants of Cleveland have trichinosis must not be interpreted as proof that Cleveland is the most highly infested area in the United States. It suggests rather that the routine diagnostic methods employed by earlier investigators were fallacious. Routine examinations of the diaphragms of adult cadavers by the Baermann digestion method led previous investigators to the conclusion that approximately 13.67 per cent of all persons in or around Washington, D. C., are infested with trichinae, 17.5 per cent in Minneapolis and Rochester, N. Y., 24 per cent in San Francisco and 27.6 per cent in Boston. Hall and Collins,<sup>1</sup> however, showed that the routine Baermann technic failed to detect about 29.3 per cent of the positive cases. Evans<sup>2</sup> of the Institute of Pathology, Cleveland, therefore supplemented this routine diagnostic method by application of the newer compression microscope technic. In this technic 1 Gm samples of the diaphragm, intercostal muscle and sternomastoid muscle are compressed

between two pieces of plate glass and examined microscopically. Parallel digestions were made with 100 Gm samples of the same muscles. Diaphragmatic digestion alone revealed the presence of twenty cases of trichinosis in 100 consecutive necropsies. This is about the average of the percentages reported by previous investigators. Many cadavers, however, whose diaphragms were negative showed trichinae in one or both of the skeletal muscles. Combining all positive data, Evans found thirty-six positive cases of trichinosis in the first hundred Cleveland necropsies studied by his double technic. Applying the implied correction coefficient (36/20) to the percentages previously reported from other cities, one would conclude that there are presumably the following percentages of trichina infestation in other American cities: Washington, D. C., 24.6 per cent, Minneapolis and Rochester, N. Y., 31.5 per cent, San Francisco 43 per cent and Boston 49.7 per cent, an average of 37 per cent infestation of the urban population of the United States. There is no way, of course, of estimating the resulting social or economic loss, but the estimated 48,000,000 cases of trichinosis in the United States is far from being a national asset.

### TUBERCULOSIS IN DRESSED POULTRY

About 3 per cent of the dressed poultry offered for sale in American markets is infected with tuberculosis. In order to test for the possible presence of tubercle bacilli in dressed poultry, W. H. Feldman<sup>1</sup> of the Mayo Foundation removed spleens aseptically from 125 fowls at the time of evisceration by a local dealer. The fowls thus examined included sixty-six young chickens, thirty mature hens, eighteen domestic ducks, four turkeys, three capons and four wild ducks. Each spleen was emulsified in 5 cc of sodium chloride solution, and 1 cc of the resulting emulsion was distributed over the surface of four tubes of egg yolk glycerin agar. The tubes were incubated at 37 C for ten weeks. Positive growths of acid-fast bacilli were obtained from four spleens. One young chicken, two adult hens and one domestic duck were the sources of these four organs. Subcultures from each of the four cases were inoculated in duplicate into guinea pigs, rabbits and chickens. All guinea pigs were without macroscopically demonstrable lesions when killed from six to eight weeks later. Three of the eight rabbits died within two to eighteen days, presumably from intercurrent infection. The five remaining rabbits died or were killed from one to two months later. At necropsy each of the five showed extensive tuberculous lesions. The eight chickens died or were killed at the end of from six to eight weeks, all showing extensive tuberculosis of the so-called Yersin type. From this evidence the investigator concluded that each of the four positive spleens was the carrier of virulent tubercle bacilli of the avian type. Since virulent tubercle bacilli are thus present in about 3 per cent of apparently normal fowls and since no practical method of postmortem inspection will disclose their presence, Feldman concludes that the rearing of fowls for food markets should be prohibited in environments known to be infected with avian tuberculosis.

# ORGANIZATION SECTION

## CITIZENSHIP AND MEDICAL LICENSURE

J E McINTYRE, M D

Secretary, Michigan State Board of Registration in Medicine  
LANSING, MICH

In the formulation of rules by boards of medical registration and in the preparation of proposed legislation and proposed amendments relative to the practice of medicine in the several states, provision has been made and is being made in many of the states for the requirement of citizenship for admission to the practice of medicine. In some states the requirement is made by rule of the medical board in others the provision is by statute.

It is interesting to note that most states have already required either United States citizenship or first papers as a condition precedent to taking the state board examinations. Only the following states require neither full citizenship nor first papers at the present time: California, Illinois, Massachusetts, New Hampshire, New Mexico, New York, Ohio, Texas, Utah and the District of Columbia. Either by state law or by a ruling of the state boards of registration in medicine the following states now require full United States citizenship: Alabama, Arkansas, Delaware, Florida, Georgia, Indiana, Kansas, Kentucky, Michigan, Missouri, Montana, Nevada, Nebraska, North Carolina, North Dakota, Oklahoma, South Carolina, South Dakota, West Virginia, Wyoming and, except in the case of Canadians, Arizona, Iowa and Minnesota. States now requiring that first papers for United States citizenship must be taken out are Colorado, Connecticut, Idaho, Louisiana, Maine, Mississippi, New Jersey, Pennsylvania, Rhode Island, Virginia, Washington and Maryland except in the case of Canadians. In addition to these requirements there is a great variety of other restrictions. In some states such as South Carolina and Wyoming, foreign graduates are not accepted under any circumstances. In some other states there is a requirement of a senior year's work in an approved United States medical school and a one year rotating internship in a United States hospital approved for internship training. Still others require that the candidates pass the National Board examination and apparently there is no uniformity whatever as to these special requirements.

In any discussion of this question, the paramount consideration should and must be the maintenance of the standards of health of the public. The primary reason for the establishment of boards of registration and the basis for enacting laws relative to the practice of medicine has been and must be such maintenance of high standards of public health by regulation of the practice of medicine. Of course doctors individually quite naturally consider the economic aspect of the question. In these times of unemployment and financial difficulty it is somewhat open to question whether the profession of medicine stands to suffer more from the competition of newcomers than do other professions and industry generally. It is probably true that in certain areas the influx of well trained foreign physicians has caused a

definite hardship to American doctors in certain communities, particularly in the larger cities. It is not the function and duty of medical boards to promote the economic security of doctors as a class but to promote and maintain high standards of education and practice in the field of medicine. Indirectly, those entitled to economic protection by reason of high standards of efficiency, ability and ideals of public service are actually benefited by able administration in boards of medicine. We must seek to eliminate the unfit. The single question therefore arises as to whether alien nationality becomes a factor of unfitness.

I find that it is the consensus of both physicians generally and students of sociology that the adherence to high ethical standards of medical practice constitutes an important factor in the service of a physician to his community. Included in such high ethical standards are standards of social responsibility, a sincere respect for our governmental endeavors for the promotion of public health, the assumption of responsibility of common social welfare, respect for our fundamental system and operation of government and, I might add, a sincere concern for the maintenance of high standards of morality in relation to those matters which our social order and system of government have decreed to be part of our moral fiber. Obviously, the alien who can meet these tests must be the exception rather than the rule of type to be found. It is therefore fitting and proper that we, as physicians, adopt the premise that citizenship of the United States should be included in the qualifications of the individual in whose hands is placed the responsibility for the moral and spiritual, as well as the physical, well-being of the citizens of any community. Thus I have pointed out the basis for the assumption that it is socially expedient and advisable to require citizenship as a condition precedent to the practice of medicine.

### THE QUESTION OF LEGALITY

The next question which confronts us, granted that such requirement is expedient and advisable, is whether such provision by rule of the medical board or by statute in any state is legal, that is whether it would be sustained in courts of last resort if attacked by any individual or group. The precise question of whether citizenship may be required as a condition precedent to the practice of medicine has never been before the United States Supreme Court. Examination of the decisions, however, of the United States Supreme Court and of the supreme courts of the various states relative to kindred questions indicates that arguments may be advanced against the validity of such provisions. However, analysis of these decisions does not indicate that the courts, because of such precedents, would decline to sustain such legislation providing for the citizenship requirement. With the help of the Bureau of Legal Medicine and Legislation of the American Medical Association and able lawyers interested in the problem,

I have made a summary of some of the decisions in relation to the question applied to certain occupations.

The constitution of the United States, article VI, clause 2, provides

This Constitution, and the laws of the United States which shall be made in pursuance thereof, and all treaties made, or which shall be made, under the authority of the United States, shall be the supreme law of the land, and the judges in every State shall be bound thereby, any thing in the constitution or laws in any State to the contrary notwithstanding

Anything in the constitution or laws of any state, therefore, that purports to require citizenship as a condition precedent to the issue of a license to practice medicine or to the practice of dentistry is legally void and without force and effect if contrary to the provisions of the constitution of the United States or of any treaty made by virtue of that constitution

Under the constitution, the crux of our problem lies in the interpretation the Supreme Court will make of the fourteenth amendment which reads as follows

All persons born or naturalized in the United States and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside. No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States, nor shall any State deprive any person of life, liberty or property, without due process of law, [and then as it especially applies to us, the following last clause of the amendment] nor deny to any person within its jurisdiction the equal protection of the laws

The right of a state to enact laws discriminating against the employment of aliens in private industry came squarely before the United States Supreme Court in *Truax v. Raich* decided in 1915. This case arose under an Arizona statute that undertook to require every employer of more than five workers at any one time to employ not less than 80 per cent of qualified electors or native born citizens of the United States. An alien who was in danger of losing his employment because of this statute appealed to the courts for protection. The case having reached the United States Supreme Court, the court said

Being lawfully an inhabitant of Arizona, the complainant is entitled under the Fourteenth Amendment to the equal protection of its laws. The description 'any person within its jurisdiction,' it has been frequently held, includes aliens. The provisions said the court, 'are universal in their application to all persons within their territorial jurisdiction, without regard to any differences of race, of color, or of nationality, and the equal protection of the laws is a pledge of the protection of equal laws'

It is sought to justify this act in an exercise of the power of the State to make reasonable classifications in legislating to promote the health, safety, morals, and welfare of those within its jurisdiction. But this admitted authority, with the broad range of legislative discretion that it implies, does not go so far as to make it possible for a state to deny to lawful inhabitants, because of their race, or nationality, the ordinary means of earning a livelihood

The authority to control immigration—to admit or exclude aliens—is vested solely in the Federal Government. The assertion of an authority to deny to aliens the opportunity of earning a livelihood when lawfully admitted to a State would be tantamount to the assertion of the right to deny them entrance and abode for in ordinary cases they cannot live where they cannot work

The United States Supreme Court had been called on to pass on a similar question in the Chinese Laundry Cases, covered by the citation *Yick Wo v. Hopkins*,

decided in 1886, cited in *Truax v. Raich*, supra. The Chinese Laundry Cases arose under a San Francisco ordinance relating to the establishment and maintenance of laundries. On its face the ordinance did not discriminate against Chinese, but it was so administered as to operate to that end. In holding the ordinance unconstitutional, the United States Supreme Court said

The Fourteenth Amendment to the Constitution is not confined to the protection of citizens

These provisions are universal in their application, to all persons within the territorial jurisdiction, without regard to any differences of race, of color, or of nationality, and the equal protection of the laws is a pledge of the protection of laws

The constitutionality of a statute forbidding the licensing of aliens as barbers came before the Supreme Court of Michigan in 1902, in *Templar v. Michigan State Board of Examiners of Barbers*. Section 5 of act 212 of the Public Acts of Michigan, 1889, provided for the examination and licensing of barbers, but it provided that no person should receive a license who at the time of his examination was an alien. This section, the Supreme Court of Michigan held, so far as it discriminated on account of citizenship, was repugnant to the fourteenth amendment, as denying equal protection of the law. The court said

In the exercise of the police power, the legislature has the undoubted right to require, as a prerequisite to his plying his trade that he submit to an examination. But had it the right to require citizenship? If it had the right to couple that with other requirements, it would have the same right to make that the only requirement. In other words, it would have the right to exclude alien labor wholly. We think the cases cited demonstrate that it had not this power. To hold that he is not entitled to practice this calling, because not a full citizen of the United States, is to deny him rights which are preserved by the fourteenth amendment

Not only does the fourteenth amendment of the federal constitution seem to preclude a state from denying to aliens as such, the right to work in the state, if the alien is physically, morally and qualified by training to work, but our treaties with foreign countries have a material bearing on the situation. Our treaty with Germany, for instance, signed in Washington Dec 18, 1923, and proclaimed Oct 14, 1925 (44 Stats 2132), provides in article 1

The nationals of each of the High Contracting Parties shall be permitted to enter, travel and reside in the territories of the other, to exercise liberty of conscience and freedom of worship, to engage in professional, scientific, religious, philanthropic, manufacturing and commercial work of every kind without interference, to carry on every form of commercial activity which is not forbidden by the local law and generally to do anything incidental to or necessary for the enjoyment of any of the foregoing privileges upon the same terms as nationals of the state of residence or as nationals of the nation hereafter to be most favored by it submitting themselves to all local laws and regulations duly established

Article VI, clause 2, of the federal constitution declares that the judges in every state shall be bound by all treaties made under authority of the United States, anything in the constitution or laws of any state to the contrary notwithstanding. As to the treaties, it is unlikely that any rights would be asserted, as several of the countries have repudiated their treaties with the United States, and for the further reason that our

nationals have been deprived of the benefit of such treaties in those countries

As I have already stated, the decisions of the courts holding that citizenship cannot be made a requirement for obtaining a license to pursue certain occupations or to conduct certain businesses do not indicate that the same ruling would be applied in the case of the practice of medicine. Courts have uniformly upheld legislation excluding aliens from the practice of law. While the decisions in some instances were based on the argument that a lawyer is an officer of the court and the court an agency of the state, nevertheless other reasons were given for excluding aliens from the practice of law. Under the general police power of the states where matters of health or morals are involved, such exclusions can be sustained on the premise that the type of occupation or profession is inherently one involving public morals and public health. To illustrate, the Supreme Court of the United States has upheld legislation excluding aliens from a license to sell intoxicating liquors for the reason that such occupation, of necessity involves public morals.

As I have already pointed out in relation to the question of the social advisability of such legislation, the same reasons, I am told by able lawyers, would be used by the courts in sustaining such provisions, that is on the ground that the practice of medicine involves a high degree of moral and social responsibility to the community, and respect and adherence to the morals and ethical standards of our people. I am further advised

that the cases which I have cited refer to a denial of an alien of his right to work. A license to practice medicine does not confer a right to work. It is not a right but merely a conditional privilege to be granted or withheld by the state purely in consideration of public welfare, public health and morals. Chief Justice Charles Evans Hughes, in a case involving the validity of the Oregon Dental Law, restated this oft repeated rule of law, namely, that the right to practice the healing arts is not in itself a right, but only a conditional privilege to be granted or to be withheld, as the health and welfare of the public may require. In view of the fact that courts have gone far in permitting states under their police power to regulate matters of public health and welfare, it is safe to assume that the decisions I have cited will not be controlling nor held to be analogous to this question.

In passing, I recommend that such provisions for the citizenship requirement be incorporated into the medical statutes of the states rather than left to the rules of the board, as from a standpoint of administrative law a legislative enactment of such a far-reaching requirement would withstand any attack more strongly.

#### CONCLUSIONS

I would leave the thought that, in view of the importance of the problem should any such legislative provision be attacked in any state, every cooperation and force of legal ability be provided so that a disastrous precedent will not result by reason of inadequate legal counsel and cooperation.

## AMERICAN MEDICAL ASSOCIATION STUDY ON MEDICAL CARE

### REPORT FROM THE MEDICAL SOCIETY OF DELAWARE

The study, covering the state of Delaware, which has a population of approximately 250,000, was conducted by the Medical Economics Committee of the Medical Society of Delaware. It was assisted in the distribution and the collection of forms by the state board of health and the Wilmington board of health. The compilation of the data and the preparation of the summary were made under the direction of the secretary of the state medical society. The information obtained is believed to furnish the most pertinent facts regarding the availability or lack of medical care in this area.

The information and data are based on reports from 109 physicians, or 36 per cent of the 303 physicians in active practice. No replies were received from dentists and only seven pharmacists returned their forms. The hospitals all cooperated in supplying information. There are nine general hospitals, including a contagious disease unit and a mental deficiency unit, one army hospital, one mental hospital, two tuberculosis hospitals, one preventorium and one state welfare home.

The health departments were very cooperative in furnishing information and data, and consequently the conclusions on the need and supply of medical care depends a great deal on their information. The Wilmington board of health furnishes medical services, laboratory diagnosis and sanitary supervision. The state board of health with a component unit in each county, maintains records and vital statistics, makes laboratory tests and maintains sanitation supervision, maternal and child health supervision, communicable and venereal disease controls, tuberculosis sanatoriums,

and dental hygiene and public health nurses. All schools, colleges, nurses and relief agencies also contributed valuable information to the Medical Economics Committee for this study.

The consensus of the physicians who returned the forms is that medical care is available to every one. Of 109 physicians supplying information only ten, or 9 per cent, reported that they knew of cases in which any type of medical care was not easily obtainable. Since the 109 physicians are located in all parts of the state, it can be assumed that their experiences are representative of all the physicians in the state. Therefore approximately only twenty-seven of the total 303 active physicians in the state have observed inadequacies of any type of medical care.

The Medical Economics Committee's report on the specific needs for increased facilities for the distribution of medical care and recommendations for services that should be expanded in order to make medical care more easily obtainable to certain low income groups, follow.

Delaware is a small compact and conservative state, with a per capita wealth well ahead of most of the states. Its terrain is practically level, the roads are excellent, and medical care can easily be reached. As a matter of fact, among the few instances reported of persons receiving no medical care, there must be a fair sprinkling of those who did not know how to secure such care and still another group who did not wish for care at the hands of the regular medical profession. However, by this statement it is not meant to imply that Delaware is a land of plenty, medically speaking,

because certain facilities definitely need to be expanded and there are certain services which should be enlarged, among these are

1 Increased facilities for Negro tuberculous patients. A bill is now in the legislature which, if passed, will appropriate \$150,000 to provide sixty additional beds for this purpose.

2 An increase in beds available for Negro maternity work is desirable, especially outside Wilmington. No program is at present outlined. Within the past year two hospitals in Wilmington have built new maternity wings, including a fairly adequate number of beds for Negroes.

3 There is a need for more public health nurses and/or visiting nursing service, especially in rural New Castle County. The levy court of this county is being petitioned to provide funds for this purpose, as well as an additional county physician or physicians who perhaps will serve on a part time basis.

4 The hospitals throughout the state need additional beds for general medical and surgical care despite the fact that their occupancy last year was approximately 60 to 65 per cent. This is due to the fact that there are certain peaks of the load, during which time the most urgent cases can be admitted and the less urgent cases are placed on a waiting list.

5 The care of the psychiatric sick is limited to one institution, which serves the whole state and which has been the victim for many years of a vicious degree of overcrowding. Whatever remedy for this condition there may be must come from the legislature, before which appropriation bills will be presented.

6 The mentally deficient are being cared for at a state colony accommodating some 468 patients. However, the lack of housing facilities and a sufficient budget prevents some 200 eligibles from being admitted. The legislature is now conducting a special investigation of this institution and its needs.

7 The care of certain of the aged indigents and chronically ill is centralized in one state welfare home, which replaces the three county poor houses. This is a splendid institution but is already overcrowded, and relief is now being sought from the present legislature.

8 The various clinics operated by the state board of health for venereal diseases, tuberculosis, well baby and maternal welfare are scattered throughout the state at strategic points, and this service will be expanded as, when and if the demand can be demonstrated.

9 Certain clinics, notably the birth control clinic, are being conducted by lay organizations, but the clinics so far established under these auspices are well managed and are staffed by the medical profession.

10 The care of the blind is arranged for by the Delaware Commission for the Blind, which does not operate its own clinic but which has not failed to provide adequate services through the various physicians and hospitals.

11 Care of the crippled has been given by the hospitals and medical profession and has seemed to be fairly adequate. Whatever deficiencies there may be today will be remedied within a year by a new hospital-school to be erected by the Nemours Foundation, which was endowed by the will of the late Mr. Alfred I. du Pont and which will be one of the leading orthopedic institutions in the country.

#### GENERAL NEEDS

The feeling throughout the profession is that physicians should be paid for services rendered to the indigent and near indigent. This introduces a question the answer for which is not apparent with certainty, but certain plans are in the making to provide for this feature. Wilmington has a group hospital service on the board of which the medical profession is adequately represented and which has been functioning for three years with satisfaction to all concerned. It is proposed to extend this coverage to the counties as well as to the city and to include individual memberships in addition to the employed groups, which now make up the 13,000 members. In addition to this feature there is a surprisingly large general demand for medical expense indemnity insurance, and the Medical Economics Committee of the New Castle County Medical Society is at present working on this problem and will in due time propose to the society a plan for its adoption. It is fairly certain that if and when this plan is adopted in Wilmington it will soon thereafter become statewide in its operation.

Delaware has, in lieu of county commissioners, a levy court of each county, which makes appropriations for the maintenance of hospital beds for the indigent on a per diem basis. These appropriations are inadequate, the deficits being met from private sources. If the medical indemnity insurance plan succeeds, it may be proposed that the levy courts, together with appropriations from the state, buy and keep in force the insurance for indigents and near indigents, which may in the long run prove cheaper than the present system of appropriations if there are an equal number who need this service.

In addition to such medical expense indemnity insurance there should be set up at strategic points throughout the state some central authority whose duty it shall be to weed out the indigent and near indigent from those who are able to pay their sickness expense in full or in part.

#### CONCLUSION

From these statistical data and summaries it will be appreciated that the needs in Delaware are not as acute as they are in many other communities, but it will also appear that neither the profession nor the public is fully satisfied, to remedy these defects, adequate plans and proposals are already in the making.

#### FIVE PER CENT OF ALL INCOMES FOR RELIEF

Figures recently published by the Social Security Board show that public relief payments have constituted the following percentages of total national income in each year since 1929:

Year	Per Cent	Year	Per Cent
1929	0.1	1934	4.3
1930	0.1	1935	4.4
1931	0.3	1936	4.8
1932	0.9	1937	3.8
1933	2.7	1938	5.0

The amount of money in each type of income in 1938 was as follows:

Compensation of employees	\$39,869,000,000
Entrepreneurial income	12,348,000,000
Dividends and interest	8,186,000,000
Payments to veterans	57,000,000
Relief and social insurance	
Direct relief	\$1,005,000,000
Work relief	2,216,000,000
Insurance benefits	503,000,000
Total	\$64,184,000,000

## OFFICIAL NOTES

### MEETING OF THE COUNCIL ON INDUSTRIAL HEALTH

The third meeting of the Council on Industrial Health took place January 11 at the Association Headquarters. Those attending were Drs. Harvey Bartle, Leroy U. Gardner, Henry H. Kessler, Anthony J. Lanza, Allen D. Lazenby, Earl D. Osborne, C. W. Roberts, Stanley J. Seeger, Clarence D. Selby, and Carl M. Peterson. Drs. Seeger and Lazenby were elected chairman and vice chairman respectively for the 1939 term.

Other transactions of interest to the profession were as follows:

1 The Committee on Nomenclature reported that its project to provide the profession with a compendium of terms and acceptable definitions relating to industrial health is more than half completed. The authoritative character of the final published material will be augmented by the use of consultants.

2 The Council has on file information regarding most agencies interested in industrial health. It is planned to attach information of this character in the form of an appendix to the published material on nomenclature.

3 Data regarding available opportunities for instruction of physicians in the fundamentals of industrial hygiene were presented. Inadequate provision of undergraduate, graduate and postgraduate training resulted in the formation of a subcommittee to determine the most effective contribution the Council could make for improvement.

4 Additional plans were made for the issuance of useful and authoritative articles to impress on the general profession its opportunities and responsibilities in the industrial health movement. A series of articles is contemplated on medical organization in industry.

5 The Council decided to continue the Congress on Industrial Health as an annual function.

6 At the request of the Council, committees on industrial health and related subjects have been formed in a number of the state medical associations. The importance of these groups and the necessity for regular interchange of information was recognized. A subcommittee was formed to undertake this assignment.

7 The Council decided to continue the development of a clearing house of information as a necessary and desirable service to the medical profession.

8 The best means for analysis and review of medical progress standards and interest under workmen's compensation procedure were discussed, especially cooperative action with official agen-

cies in the constituent and component societies. In this connection the Council undertook to explore the possibilities for a more scientific approach to the relationships existing between trauma and disease to determine if therein lie better prospects for extraprofessional understanding and acceptance of medical opinion regarding etiology.

9 Conversations with representatives of rehabilitation and compensation groups were deferred until the Council had a better opportunity to discover the exact nature of the problems under discussion and the degree of medical interest involved.

10 The relations of the Council on Industrial Health with the sections of the Scientific Assembly, more particularly the Section on Preventive and Industrial Medicine and Public Health, were considered.

11 The Council agreed that its activities would be facilitated by holding two meetings annually, one in conjunction with the Annual Congress early in the year, and another at midyear subject to adopted regulations.

12 The tenure of office of members of the Council was determined and nominations were considered to fill one vacancy in the present membership.

### RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title *Your Health*, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).

Changes in this time will be necessary to take into consideration daylight saving time. Announcement of this change will appear in advance in *THE JOURNAL*. Owing to network conflicts the Chicago broadcast will not occur at 1 p. m. on Wednesday but there will be a rebroadcast from a recording over Station WGNR at 8 o'clock each Monday evening. The program broadcast each Monday will be identical with the network program of the preceding Wednesday.

It has been necessary to curtail the length of the series by omitting the last two programs, which would have been broadcast June 14 and June 21. The series, therefore, will end with the broadcast scheduled for June 7.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

March 22	Auditing the Health Record
March 29	Animal Diseases Transmitted to Man
April 5	Don't Believe Everything!

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

*Changes in Status*—S. 1706 has been reported to the Senate, proposing to provide for reorganizing agencies of the government. H. R. 1776 has passed the House, providing for the assignment of medical officers of the Public Health Service for duty on vessels of the Coast and Geodetic Survey. H. R. 3537 has passed the House, extending facilities of the Public Health Service to officers of the foreign service of the United States.

*Bills Introduced*—S. 758, introduced by Senator Wheeler, Montana, and H. R. 3694, introduced by Representative Dempsey, New Mexico, propose to amend the Federal Emergency Relief Act of 1933 for continuation of the civil works program by eliminating the requirement that an injury sustained by an employee must be of traumatic origin to entitle the employee to compensation, including medical and hospital benefits. H. R. 4740 introduced by Representative Boren, Oklahoma, proposes to extend the services of the National Bureau of Standards by providing for establishing performance standards when in the public interest. H. R. 4779, introduced by Representative Tenerowicz, Michigan, proposes to amend the federal income tax law so as to authorize the deduction of amounts paid during the year as fees to physicians and dentists, and the amount

expended, not in excess of \$500, for funeral expenses. H. R. 4791, introduced by Representative Pfeifer, New York, proposes to establish a federal Department of Health to be headed by a Secretary of Health appointed by the President from the medical profession. This bill is pending in the House Committee on Expenditures in the Executive Departments, of which Representative John J. Cochran of Missouri is chairman.

### STATE MEDICAL LEGISLATION

#### Arizona

*Bill Passed*—H. 129 has passed the house and senate, proposing to make it a felony to practice or attempt to practice medicine without having a valid recorded license so to practice issued by the State Board of Medical Examiners. The present law makes it a felony to practice or attempt to practice without having a valid recorded certificate.

*Bill Introduced*—H. 276 proposes that a person shall not be entitled to hospitalization or medical care at public expense unless he or she has continuously resided in the state for at least three years immediately preceding the date of application for relief.

**California**

*Bills Introduced*—A 1727 proposes to require hospitals to keep hospital records on file for at least three years after the persons to whom the records apply are discharged and to permit patients and ex-patients or persons they designate to examine, inspect or copy the pertinent records. S 492 proposes to direct the Director of Institutions, with the approval of the State Board of Control, to provide suitable property for one or more institutional units to be known as State Inebriate Colonies and to be used for the isolation and rehabilitation of chronic inebriates committed thereto by appropriate courts. A 2748 proposes to give the juvenile court jurisdiction over any person under 21 years of age who is afflicted with syphilis, gonorrhea or chancroid and who is in need of medical and custodial care or both.

**Connecticut**

*Bill Introduced*—S 305 proposes to establish a department of professional and vocational licensing, to be in charge of an executive secretary, who is to be a secretary of each of the licensing boards and commissions of the state, including the state board of healing arts, the medical examining board, the homeopathic medical examining board, the osteopathic board, the chiropractic board, the naturopathic board, the optometry board, the chiropody board, the dental commission and others. The executive secretary is to exercise all the powers and perform all the duties conferred or imposed on the secretary of the boards enumerated.

**Colorado**

*Bills Introduced*—H 466 proposes as a condition precedent to the issuance of a license to marry that each party to a prospective marriage present a physician's certificate that he or she has submitted to such examination including a standard serologic test as may be necessary for the discovery of syphilis and that in the opinion of the physician the party either is not infected with syphilis or is not in a stage of that disease which may become communicable. H 470 proposes to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood within ten days of the first professional visit and to submit that sample to an approved laboratory for a standard serologic test for syphilis.

**Delaware**

*Bills Introduced*—S 79 proposes to enact a law regulating the manufacture, sale, distribution or advertising of foods, drugs, cosmetics and devices. H 141 proposes to repeal the existing laws providing compensation for workers injured or acquiring stated occupational diseases in their employment and to enact a new workmen's compensation act. The bill proposes to provide compensation to workers (1) suffering personal injury arising out of and in the course of their employment, (2) contracting disease or infection as naturally results directly from the industrial injuries or (3) contracting from their employment the following occupational diseases: anthrax, lead poisoning, arsenic poisoning, phosphorus poisoning, poisoning from benzene and its homologues, wood alcohol poisoning, chrome poisoning, caisson disease, radium poison, or poisoning from carbon disulfide or hydrogen sulfide. The bill proposes to require the employer during the first thirty days after the injury to furnish reasonable surgical, medical and hospital services, medicines and supplies not to exceed in cost, however, \$150. The workmen's compensation bureau which is to administer the act, may in its discretion require the employer to furnish additional surgical, medical and hospital services, medicines and supplies as and when needed, for such further period as it shall deem necessary. H 76 proposes to direct the State Board of Trustees of the Delaware State Hospital at Farnhurst to establish a psychiatric observation clinic for the observation study, psychiatric diagnosis and treatment of persons suffering from mental and nervous diseases. H 143 proposes to prohibit the retail sale and distribution, except on the written prescription of a licensed physician, dentist or veterinarian, of barbitol, sulfonethyl methane (trional), sulfon-methane (sulfonal), diethylsulfone, diethylmethane (tetronal), paraldehyde, chloral or chloral hydrates, chlorobutanol.

**Georgia**

*Bill Passed*—S 117, to amend the chiropractic practice act passed the senate February 22, proposing (1) to require applicants for licenses to practice chiropractic to have graduated from chiropractic schools which require for graduation a period of active attendance equivalent to a standard four year college course, instead of the present requirement that such applicants have graduated from chiropractic schools requiring a course of three years of six months each and (2) to require chiropractic licentiates to renew their licenses annually and to condition that renewal on attendance during the preceding year at least one of the two "educational" programs conducted by the Georgia Chiropractic Association.

**Illinois**

*Bills Introduced*—H 324 proposes to appropriate \$25,400 for a cancer diagnostic service by the Department of Public Health. H 327 proposes to enact a separate naprapathic practice act and to establish an examining committee to examine and license persons to practice naprapathy. The bill attempts to define naprapathy as follows: Any one or any combination of the following practices, without the use of drugs, serums or operative surgery, constitutes the practice of Naprapathy: (a) examination of the human body, to ascertain the presence of defects or abnormal conditions involving the connective tissues, (b) diagnosis of aforesaid defects or abnormal conditions, (c) prescription recommendation or advice regarding treatment of aforesaid defects or abnormal conditions, (d) treatment of aforesaid defects or abnormal conditions, (e) attempting any of the foregoing practices."

**Indiana**

*Bills Enacted*—The following bills have become laws. H 21 to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of diagnosis and to submit such sample to an approved laboratory for a standard serologic test for syphilis, H 37, appropriating \$75,000 annually for the fiscal biennium beginning July 1, 1939, for the purchase and distribution free of charge to poor persons of pneumococcus serum, diphtheria toxoid, smallpox virus and typhoid bacterins. H 134 requiring both parties to a prospective marriage to present a physician's certificate as to freedom from syphilis and S 173, to regulate the manufacture, distribution and advertising of foods, drugs, cosmetics and devices.

**Iowa**

*Bills Introduced*—H 431, to amend the chiropractic practice act proposes (1) to provide that "The practice of chiropractic shall be deemed to be the adjustment by hand of articulations of the spine and other incidental adjustments, and shall include the right to use air, light, heat, water, diet and exercise, in the treatment of diseases, and (2) to prohibit a chiropractor 'from practicing operative surgery, electro-coagulation, radium in any form, general hyperpnea, osteopathy, optometry, obstetrics, x-ray treatment or administering or prescribing any drug or medicine included in materia medica and (3) to provide that every licensed chiropractor shall place on all signs used by him and to display prominently in his office the word 'chiropractor or chiropractic physician'". H 180 proposes to appropriate \$2,000,000 for the erection of a hospital for the treatment and care of the insane, to care for at least 1,500 patients. H 543 proposes to make it a ground for the revocation of a license to practice medicine, osteopathy, chiropractic dentistry, optometry or podiatry for the licentiate to be 'guilty of aiding or abetting an unlicensed person to practice either by direct employment or indirectly through subterfuge or arrangement, whereby the unlicensed person through the use of such professional services profits monetarily in any manner'.

*Bill Passed*—H 59 has passed the house, proposing to condition the issuance of a license to marry on the presentation by both parties to the proposed marriage of certificates from licensed physicians that they are either free from syphilis or not in a stage whereby it may become communicable, as nearly as can be determined by a thorough physical examination and such standard microscopic and serologic tests as are necessary for the discovery of syphilis. The bill proposes to limit the fee a physician may charge for such physical examination and standard microscopic and serologic tests to \$2 for each person so tested and examined.

### Kansas

*Bills Introduced*—S 328 proposes to prohibit a pupil or teacher from attending or teaching in any school public or private, unless possessing a physician's certificate that he or she has been successfully vaccinated against smallpox or that he or she is not a fit subject for vaccination. H 348 proposes to direct the State Board of Education to require a course of study in the public schools concerning the evil effects of the use of marijuana, alcohol, narcotics and hypnotic drugs. H 448 proposes to establish a board of examiners for consulting psychologists to examine and license applicants for licenses to practice as consulting psychologists. The bill proposes to make it unlawful for any one but licentiates to represent themselves as or to assume to act as consulting psychologists. Applicants for such a license must hold a degree of doctor of philosophy in psychology or in education from a college or university recognized by the board of examiners. H 509 proposes to grant to a hospital furnishing any service to a person injured by an accident not covered by the workmen's compensation act a lien on all rights of action, claims, judgments, settlements or compromises accruing to the injured person because of his injuries.

### Maine

*Bills Introduced*—S 414 proposes that in criminal cases in which the defendant is charged with operating a motor vehicle while under the influence of intoxicating liquor the results of scientific analysis of body fluids legally obtained from the defendant shall be admissible as evidence. S 416 proposes to repeal the existing laws regulating the possession or distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act.

### Maryland

*Bill Introduced*—H 392 proposes to authorize the State Board of Health to establish such minimum standards as it considers necessary for laboratories in the state except in Baltimore City, which make examinations in connection with the diagnosis and control of human diseases.

### Michigan

*Bills Introduced*—S 140 proposes to repeal existing laws relating to coroners and to create a medical examiner system in the state under the direction of a state medical examiner appointed by the governor. The board of supervisors of each county is, with the approval of the state medical examiner to appoint a licensed physician to serve as a county medical examiner. A county medical examiner is to have jurisdiction only in cases in which a person is supposed to have come to his or her death by violence without medical attendance or as a result of an abortion or in case a prisoner dies in any city jail. H 215 proposes to authorize the organization of corporations to establish maintain and operate nonprofit medical care plans whereby medical care is provided at the expense of the corporations to such persons or groups of persons of low income as become subscribers to such plans under contracts which entitle each such subscriber to definite medical and surgical care appliances and supplies, by licensed physicians in their offices in hospitals and in the home. The bill states that medical care is not to be construed to apply to hospital service. H 277 proposes to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis.

### Minnesota

*Bills Introduced*—S 781 and H 853 propose to prohibit except on the written prescription of a licensed physician, dentist or veterinarian, the retail sale or distribution of barbituric acid, propional, isopropyl, dial, neonal sandoptal amylal phenobarbital phanodorn noctal allonal medinal or any preparation mixture or other substance containing any of the aforementioned substances. S 683 proposes that any graduate of a chiropractic school who (1) made application for a certificate of registration in the basic sciences before Oct 1 1927 (2) is an honorably discharged soldier of the World War and (3) was a resident of the state prior to and since May 1 1925 shall be entitled to

receive a certificate of registration in the basic sciences without examination if he makes application within thirty days after this bill becomes a law.

### Missouri

*Bills introduced*—S 132 proposes to create in the State Board of Health a division of child hygiene to issue educational literature on the care of the baby and the hygiene of the child to study the causes of infant mortality and the application of preventive measures for the prevention and suppression of the diseases of childhood to supervise and regulate the physical inspection of public school children and to inspect sanitary and hygienic conditions on public school property. H 152 proposes that hereafter in the administration of any public health project in the state all doctors of medicine and all doctors of osteopathy must be given equal rights and privileges. H 500 proposes to require every person licensed to practice medicine in the state annually on or before December 31 to register with the State Board of Health and to pay an annual fee of \$1. H 462 to amend the medical practice act, proposes to require an applicant for a license to practice medicine, in addition to educational qualifications now required by law, to furnish evidence of "completion of premedical education consisting of a minimum of sixty semester hours of college credit in acceptable subjects from a reputable college or university approved by the board of health. H 548 proposes to permit any person to file an information in the nature of a quo warranto or an action to enjoin or oust from the unlawful practice of medicine any person who practices medicine or surgery without being licensed to do so.

### Nevada

*Bills Introduced*—S 8 proposes to establish a state sanatorium for the treatment and care of persons suffering from tuberculosis, to be subject to the control and jurisdiction of the State Department of Health. A 178 proposes to authorize the sexual sterilization of insane, feeble-minded or epileptic inmates of state institutions. The bill further proposes that all prisoners who have previously been convicted of two or more felonies are to be subject to observation and examination by any mental hygiene clinic and, if it is found that the criminality is caused by mental abnormality or mental disease the prisoner may be sterilized. A 165 proposes to prohibit a county clerk from issuing a marriage license unless the applicant files a certificate of the examining physician, duly signed and dated within fifteen days prior to the application, that physical examination and serologic tests do not disclose syphilis in the applicant that the applicant has submitted to a Wassermann or Kahn or other similar standard laboratory blood test, and that in the opinion of such physician at the time of the examination the applicant either is not infected with syphilis or is not in a stage of that disease which may become communicable.

*Bill Passed*—A 149 passed the assembly March 2 proposing to enact a law regulating the sale distribution and advertising of foods drugs cosmetics and devices.

### New Hampshire

*Bill Passed*—H 232 has passed the house and senate proposing to authorize the formation of nonprofit hospital service corporations to maintain and operate plans whereby hospital care may be provided at the expense of the said corporations by hospitals to subscribers to said plans under contracts entitling the subscribers to stated hospital services.

### New Jersey

*Bills Introduced*—S 144 proposes to authorize the board of education of any school district to require immunization to diphtheria as a prerequisite to school attendance. A 210 proposes extensive amendments to the existing medical practice act. Most important the bill proposes that after 1945 applicants for licenses to practice chiropractic must meet the same educational requirements as are imposed on applicants for licenses to practice medicine and surgery. Such applicants apparently after that date would be given licenses to practice medicine and surgery without restriction. The bill also proposes to limit licensure to citizens of the United States and to authorize a court of chancery to enjoin the unlicensed practice of medicine. A 245 proposes so to amend the state pure food and drug act as (1)\* to include also cosmetics and therapeutic

devices and (2) apparently to make it conform generally to the Federal Food, Drug and Cosmetic Act. S 171 proposes to require every physician, pharmacist and head of every hospital, when any person infected with syphilis, gonorrhea or chancroid applies for treatment, to report the facts to the State Department of Health. The bill further proposes to require any person infected with venereal disease to consult at once a licensed physician or hospital "or any person who practices healing by spiritual, religious or mental means." S 167, to amend the medical practice act, proposes to limit licensure in the healing arts to citizens of the United States. The present law permits the licensing of persons who have declared their intention of becoming citizens.

#### New Mexico

*Bill Passed*—H 282 passed the house February 28 proposing to require every practitioner of the healing art attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample to a laboratory approved by the State Department of Public Health or to the State Department of Public Health for a standard serologic test for syphilis.

#### New York

*Bills Introduced*—S 965, to supplement the medical practice act, proposes to enact a series of provisions with respect to the practice of physiotherapy, which the bill states "means the use for the treatment of diseases, pain, injury, deformity, or physical condition, by means of actinotherapy, hydrotherapy, mechanotherapy, thermotherapy and electrotherapy, exclusive of x-rays." The bill proposes to require a licensed physiotherapist to register annually with the secretary of the board of medical examiners. The bill seems to lack any provision whereby persons other than those now licensed to practice physiotherapy may obtain such licenses. S 969 proposes to prohibit the practice of radiology except by licensed physicians, osteopaths, dentists or chiropractors subject, however, to the conditions and limitations of their respective licenses. A 1308 proposes that no person who has a communicable or contagious disease shall work or be permitted to work in a factory in which a food product is manufactured. The bill also proposes to require any such employee, when required by a medical inspector of the labor department to submit to a physical examination. A 1416 proposes to reimburse annually to a city maintaining a hospital for the care and treatment of persons afflicted with tuberculosis one half of the amount appropriated during the preceding year by the city for the maintenance of the hospital. A 1417 proposes to authorize any city common council to convey to the state any hospital owned and operated by the city for the care and treatment of tuberculosis. Any hospital when so required by the state is to be deemed a state tuberculosis hospital and is to be under the jurisdiction and control of the State Department of Health. The cost of its operation and maintenance shall be provided by state appropriations. A 1428 proposes that a license to practice osteopathy shall entitle the holder thereof to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics and biologic products. The present law specifically states that a license to practice osteopathy shall not permit the holder thereof to administer drugs or perform surgery with the use of instruments. A 1433 proposes to prohibit, except on the written prescription of a licensed physician, dentist or veterinarian, the retail sale or distribution of barbital, sulfon ethylmethane (trional), diethylsulphur diethylmethane [sic] (tetronal), carbromal, chloral or chloral hydrate or chloro butanol. A 1280 proposes to establish in the motor vehicle bureau a board of motor vehicle accident compensation to assure the payment of medical and hospital expenses resulting from motor vehicle accidents. The bill proposes to require every owner of a motor vehicle either to furnish bond or an insurance policy or to pay \$5 in addition to the registration fee now required by law. Any person injured in a motor vehicle accident, if the car involved in the accident is uninsured, may recover from the fund so created expenses incurred for medical, surgical, nursing and hospital services up to \$600 to be ratably distributed among those injured. A 1238 and S 914 propose to include employment in hospitals within the workmen's com-

pensation act. A 1265 proposes to prohibit the performance of an operation, the purpose or effect of which is to change or alter the skin or tissues of the fingers or thumbs so as to alter finger patterns or fingerprints. The bill also prohibits the performing of any operation of plastic surgery on a known criminal the purpose or effect of which is to alter his personal appearance and make identification and apprehension difficult. A physician, the bill proposes, must report immediately by telephone, if possible, to appropriate police authorities all requests for operations which seem to come within the prohibitions of this bill. A 1213 proposes to enact what the bill cites as the New York uniform food, drug and cosmetic act to regulate the manufacture, distribution or advertising of foods, drugs, cosmetics and devices. A 1585 proposes to prohibit private hospitals from requiring or permitting any employee to work more than eight hours in any day nor more than forty eight hours in any calendar week.

#### North Carolina

*Bills Introduced*—S 185 proposes to collect from each applicant for an automobile license 50 cents in addition to existing license fees, to establish the North Carolina Highway Accident Hospitalization Fund, which when it totals \$100,000 is to pay \$3 a day for up to twenty-one days of hospitalization for every resident of the state sustaining a motor vehicle injury and needing hospital care for his injuries. Any indigent who has suffered a motor vehicle injury is to be entitled to full hospital service for up to twenty-one days and to have the fund pay the entire cost. Persons who are not indigents are to be permitted to apply the amount payable from the fund as a credit on their hospital bill. S 232 proposes to enact what it cites as the North Carolina food, drug and cosmetic act to regulate the manufacture, distribution and advertising of foods, drugs, cosmetics and therapeutic devices.

#### Ohio

*Bills Introduced*—H 204, to amend the law prohibiting a physician from testifying concerning a communication made to him by his patient in that relation except by the express consent of the patient, proposes that if the patient is dead the physician may testify by the express consent of the surviving spouse, personal representative or heir of the patient. H 379 proposes, as a condition precedent to the issuance of a license to marry, that each party to the proposed marriage present a certificate of a physician that he or she is free from epilepsy, feeble-mindedness and insanity and is not infected with syphilis, or is not in a stage of that disease which may become communicable as nearly as these facts can be determined by examination of the party and by the application of standard laboratory tests for syphilis.

#### Oklahoma

*Bill Introduced*—H 354 proposes to prohibit a licensed practitioner of the healing art, in making professional calls away from his office from charging or collecting more than his regular fee for each call plus 50 cents per mile for each mile actually and necessarily traveled in going from his office to the place where he attended the patient.

#### Oregon

*Bills Introduced*—S 426 proposes to prohibit the operation of a maternity hospital or other place for the reception, care and treatment of women during pregnancy or within ten days after delivery unless licensed by the State Board of Health. S 435 is apparently a proposal to permit chiropractors, osteopaths and naturopaths to practice "massotherapy," which is defined by the bill to include all terms defined in section 1 of the bill. Section 1 reads as follows: "For the purposes of this act the following terms shall be construed respectively to include and mean: 1 The word 'massotherapy' shall mean massage. 2 The word 'hydrotherapy' shall mean the use of water for treating elimination through the pores of the skin. 3 The word 'physiotherapy' shall mean light therapy, galvanism, faradism, high frequency, diathermy, sinusoidal currents, short wave and any or all other phases of physiotherapy. 4 The word 'electrotherapy' shall mean the therapeutic use of electricity. 5 The words 'physical therapy' shall

mean the use of natural forces such as light, heat, air, water and exercise [sic], a thorough knowledge of physiological and pathological effects on anatomy of the above modalities in the treatment of disease. The bill further provides that all masseuses or masseurs or other technicians having establishments and giving treatments as defined in this act and who have been engaged in practice in the state for six years or more, and who in the opinion of the State Board of Chiropractors or Naturopaths are competent, shall be licensed (by whom the bill does not state) to practice massotherapy as defined in the bill. S 475, to amend and supplement the laws relating to the practice of osteopathy, proposes (1) to deprive the board of medical examiners of its present jurisdiction in examining and licensing persons to practice osteopathy and (2) to establish an independent board of osteopathic examiners to examine and to license persons to practice osteopathy. The bill states that "Osteopath" or "osteopathic physician" or "osteopathic physician and surgeon" shall mean one who practices osteopathy and the science of healing as taught in the branches and embraced in the subjects covered by the examination provided for by the act. The act requires applicants to be examined in anatomy, physiology, chemistry, surgery, bacteriology, histology, pathology, gynecology, obstetrics, theory and practice of osteopathy, diagnosis and hygiene and public health.

#### Pennsylvania

*Bills Introduced*—S 129 proposes as a condition precedent to the issuance of a license to marry, that each party to a proposed marriage present a physician's certificate that the party has submitted to an examination and is free from communicable tuberculosis, is not infected with communicable syphilis as determined by a standard laboratory blood test made not more than ten days preceding the application for license. H 367 proposes that, whenever in any civil or criminal proceeding issues arise on which the court deems expert evidence is desirable, the court may appoint one or more experts, not exceeding three, on each issue to testify at the trial.

#### South Carolina

*Bill Passed*—H 361 passed the house February 24 proposing to require every physician, midwife, nurse or other person attending at the birth of a child to instill, or have instilled in the eyes of the baby, within one hour after birth, a 1 per cent solution of silver nitrate, or some equally effective prophylactic approved by the State Department of Public Health, for the prevention of blindness from ophthalmia neonatorum. A record of such administration or instillation must be reported on the birth certificate, showing the time with respect to the birth and the kind of prophylactic administered.

*Bill Introduced*—S 325 proposes, in effect, to grant to a physician, dentist, trained nurse, or hospital furnishing care or treatment to an injured person a lien on all judgments and settlements accruing to the injured person because of his injuries.

#### Tennessee

*Bills Introduced*—H 997 proposes to authorize the organization of corporations to operate nonprofit hospital service plans whereby hospital service may be provided by one or more hospitals which have contracted with such corporations to persons who become subscribers to such plans. H 821 and S 584 propose to establish a division of tuberculosis control in the Department of Public Health, which is to provide financial aid to counties or municipalities in the maintenance of patients in tuberculosis hospitals or in wards or pavilions in approved hospitals other than tuberculosis hospitals for the treatment and care of indigent persons sick with tuberculosis. H 1038 proposes to require a food handler to undergo a physical examination and blood test every six months to ascertain whether or not he or she has tuberculosis or venereal disease and to make it unlawful to employ any such person unless he or she presents a physician's certificate as to absence of tuberculosis or venereal disease. H 1054 proposes to require all public school teachers to undergo annually a physical examination and to submit to blood tests to determine the presence or non-presence of tuberculosis and venereal disease. H 1039 proposes to require physicians attending pregnant women to make the

necessary blood tests of the patient to determine the presence of syphilis prior to the birth of the issue. S 868 and H 1174, to amend the workmen's compensation act, propose to require an employer to provide an injured workman such medical, surgical and hospital services as are reasonably required to cure or relieve from the effects of the industrial injury. The present law limits such liability to \$200 and requires the aid to be rendered only during the first thirty days after knowledge of injury. S 1003 and H 1385, to amend the workmen's compensation act, proposes to require an employer, during sixty days after notice of an industrial accident, to furnish free of charge to the injured workman such medical and surgical treatment, medicine, medical and surgical supplies, crutches and apparatus as may be reasonably required, provided, however, that the total liability of the employer for medical and surgical services shall not exceed \$100 and for hospital services shall not exceed \$300.

#### Texas

*Bill Introduced*—H 818 proposes to prohibit the admission of a child to school "for the first year of its school life" until he or she has been successfully vaccinated for the prevention of smallpox, typhoid and diphtheria. The bill proposes to make it the duty of the county health officers and city health officers of the state to administer such vaccine as is necessary free of charge.

#### Vermont

*Bills Introduced*—H 285 proposes to establish within the Department of Public Welfare a psychiatric clinical division to provide local and traveling clinics at such places and at such times as will efficiently examine (1) children under the supervision and jurisdiction of the public welfare department, (2) dependent, neglected or delinquent children against whom court proceedings have been instituted, and (3) children against whom complaints or petitions have been made to the state probation officer. H 319 proposes, as a condition precedent to the issuance of a license to marry, that each party to the proposed marriage present a physician's certificate that he or she has been given such examination as may be necessary for the discovery of syphilis, including a standard serologic test, made not more than thirty days prior to the date of application for a marriage license, and that in the opinion of the physician the party either is not infected with syphilis or if so infected is not in a stage of that disease which is or may become communicable to the marital partner.

#### Washington

*Bill Enacted*—S 114 has been enacted as Laws, 1939, C 46, proposing to establish at Soap Lake an institution to be known as the McKay memorial research hospital for the treatment and care of persons afflicted with Buerger's disease and for study of the disease and of the properties of the waters of Soap Lake.

*Bills Introduced*—S 187, to amend the law establishing in the department of social security a division for improving the condition of the blind and for preventing blindness and providing certain monthly payments to needy blind persons, proposes that medical care or other corrective treatments, such as glasses, earphones and all other appliances, shall be provided by the state to such recipients, and the cost thereof shall not be deducted from blind assistance allotments. S 374 proposes to require a physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis. S 373 proposes as a condition precedent to the issuance of a license to marry, that both parties to the proposed marriage present physicians' certificates that they have been given such examination, including a standard serologic test, as may be necessary for the discovery of syphilis and that, in the opinion of the physicians, the applicants are not infected with syphilis or, if so infected, are not in a stage of that disease which is or may become communicable to the marital partner.

#### West Virginia

*Bill Passed*—S 159 passed the senate February 22 proposing to make it unlawful for any person to use the prefix "Doctor" or "Dr" in connection with his name in any letter, business

card, advertisement, sign or public display of any nature, without affixing thereto suitable words or letters designating the degree which he holds

### Wisconsin

**Bills Introduced**—S 183 proposes (1) to supplement the chapter of the statutes entitled "Construction of Statutes" by proposing definitions of (a) "physician," "surgeon" and "orthopedic surgeon" that will include persons authorized to practice osteopathy and surgery, (b) "medical" and "practice of medicine" that will embrace the activities of osteopaths and (c) "medical college" that will include osteopathic schools, (2) in effect to permit an osteopath to execute the examining physician's certificate required for admission to the Wisconsin general hospital or for commitment to governmental and private insane asylums, and (3) apparently to give all physicians as defined, equal rights in the treatment of venereal disease. S 192 to amend the medical practice act, proposes that Applicants for license to practice osteopathy and surgery, after July 1, 1945, in addition to having a diploma from a reputable professional college approved and recognized by the board [of medical examiners] shall establish having completed a two years college course including physics, chemistry, biology and either German or French, and if the professional college from which a diploma is presented does not require for graduation a hospital internship of at least twelve months in addition to a four years course, such applicant shall present a certificate that he has served at least twelve months internship. S 185 proposes that any person licensed before 1916 to practice osteopathy in the state is to have the right and privilege to exercise his professional judgment in the treatment of patients. The bill further provides that Any license heretofore or hereafter issued [apparently referring to a license to practice osteopathy] shall legally qualify the holder for service in the capacity of physician under any statute of this state which provides for or permits the employment, appointment, election, or selection of a physician for any purpose whatever concerning health, service or

relating to health matters, without other recommendations by a professional society or association." S 186 proposes that "Any sick or injured person entitled by statute or otherwise to the services of a physician, whose services for such person are to be paid for in whole or in part by said person's employer, or by some insurance carrier of such employer, or by any municipality, or by some society or association, or by some other person or persons, corporation, or partnership, shall be entitled to have the unrestricted and free choice of a physician to care for and administer to him." A 392 proposes that "All employes in all state charitable and penal institutions shall be employed on the eight hour day basis." A 401 proposes to authorize the incorporation of "associations on a cooperative basis. 1 By individuals for the purpose of securing or paying for medical and hospital care for themselves and their families. 2 By a group of physicians for the purpose of providing medical and hospital care." Associations so formed are not to be subject to any of the insurance laws of the state. The bill also proposes to make it unlawful for any hospital, supported in whole or in part by public funds or wholly or partially exempt from taxation, to deny to any patient or any physician the facilities of such hospital because of affiliation with a cooperative association. The bill also proposes that no physician otherwise eligible for membership shall be excluded from membership in the state or county medical society because he enters into contracts with individuals or cooperative associations to furnish medical service on the basis of a stipulated sum to be paid periodically or because he is employed by an individual, a partnership or a cooperative association furnishing medical services on such terms. A 411 proposes, in effect, to permit chiropractors to treat, at the expense of the employer, workmen injured in the course of their employment. The bill proposes to give the injured workman the right to "the attendance of any licensed chiropractor" and to require the employer to maintain a panel of licensed chiropractors ready to undertake the treatment of such of employees as may be injured.

## WOMAN'S AUXILIARY

### WINNERS IN THE HYGEIA CONTEST

The American Medical Association offered \$150 in cash prizes to the county auxiliaries obtaining the largest number of subscription credits to *Hygeia* during December 1938 and January 1939.

The winners were

Group I Auxiliaries with a membership of from one to forty-nine

\$50 prize to Union County Ark. Mrs. Warren S. Riley, Hygeia chairman, El Dorado, Ark.

Group II Auxiliaries with a membership of from fifty to 199

\$50 prize to Berks County, Pa., Mrs. William F. Krick, Hygeia chairman, Reading, Pa.

Group III Auxiliaries with a membership of more than 200

\$50 prize to Cook County, Ill., Mrs. W. J. Waininger, Hygeia chairman, Chicago.

Honorable Mention was given to the following county chairmen

Duval County, Fla., Mrs. Dan Funkenstein, chairman, Jacksonville, Fla.

Baldwin County, Ga., Mrs. C. H. Richardson, president, Milledgeville, Ga.

Lafayette County, Kan., Mrs. C. S. McGinnis, chairman, Parsons, Kan.

Orleans Parish, La., Mrs. Henson Coon, chairman, Monroe, La.

Park Region District, Minn., Mrs. L. C. Combacker, president, Fergus Falls, Minn.

Washington County, Minn., Mrs. R. J. Joseph, chairman, Stillwater, Minn.

Albany County, N. Y., Mrs. F. L. Coughlin, chairman, Albany, N. Y.

Pottawatomie County, Okla., Mrs. R. M. Anderson, chairman, Shawnee, Okla.

Chelan County, Wash., Mrs. A. G. Young, chairman, Wenatchee, Wash.

Sheboygan County, Wis., Mrs. G. J. Hildebrand, chairman, Sheboygan, Wis.

Other counties that reached their quota were

Mesa County, Colo., Bulloch-Evans Candler County, Ga., St. Joseph County, Ind., Shawnee County, Kan., Wayne County, Mich., Jackson County, Mo., Burt-Dodge-Washington County, Neb., Cayuga County, N. Y., Guilford County, N. C., Robeson County, N. C., Elk-Cameron County, Pa., Huntingdon County, Pa., Lehigh County, Pa., Mifflin County, Pa., Montgomery County, Pa., Westmoreland County, Pa., Seventh District, South Dakota, Collingsworth-Childress Hall County, Texas, Hunt-Rockwall-Raines County, Texas, Salt Lake County, Utah, Weber County, Utah, Clark County, Wash., King County, Wash., Pierce County, Wash., Spokane County, Wash., Walla Walla County, Wash., Kanawha County, W. Va., McDowell County, W. Va., Rock County, Wis., Washington Ozaukee County, Wis.

The final result in this year's contest was 6,242 subscriptions, as against 4,747 received in the contest last year and 3,855 in 1937.

To the Hygeia chairmen, officers and members of the various county and state woman's auxiliaries who have assisted in making this contest a success, Mrs. James D. Lester, National Hygeia Chairman, expresses appreciation.

### ARKANSAS

**Sixth Graduate Course**—The Arkansas Medical Society presented its sixth course of graduate instruction at the University of Arkansas School of Medicine Little Rock January 31 February 1. In addition to clinics papers were presented by Drs David Harvey Shipp Little Rock General Considerations of Empyema, Herbert F H Jones Little Rock, Treatment of Ureteral Calculi, Cyril M MacBryde St Louis 'Effects Obtainable with Pituitary Gonadotropic and Sex Hormones' Joseph F Shuffield Little Rock, Internal Fixation of Fractures of the Neck of the Femur, Frank D Gorham St Louis, Management of Peptic Ulcer and David T Hyatt Little Rock Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis.

### CALIFORNIA

**County Society's Building Receives Honor Award**—The Southern California chapter of the American Institute of Architects recently awarded a certificate of honor to the Los Angeles County Medical Association to recognize merit in design and execution of work in architecture and fine arts within its territory. The certificate records the chapter's belief that the library and assembly hall of the association deserve exceptional merit and its appreciation of the sympathetic collaboration with the architect and the builder which made the building possible.

**New Medical Laboratory at Stanford**—A new laboratory building has been given to Stanford University School of Medicine San Francisco by Mrs Louis Stern Palo Alto in the name of her daughter Ruth Lucie Stern. The new unit will be used for research in cancer neurology infantile paralysis childhood tuberculosis and other phases of pediatrics certain types of fever and other public health problems with special emphasis on neurology in which the donor is chiefly interested. The three story building will be designed for workshop purposes without administrative offices or lobbies and will contain thirty glass paneled workrooms.

### DISTRICT OF COLUMBIA

**Society News**—The Medical Society of St Elizabeths Hospital will hold its second annual meeting in Washington April 14. The afternoon will be devoted to the presentation of papers. Guests will include Drs Charles Macfie Campbell medical director of the Boston Psychopathic Hospital and professor of psychiatry, Harvard University Medical School Boston and Riley H Guthrie newly appointed first assistant physician at St Elizabeths Hospital. Further information may be obtained from Dr Salomon Katzenelbogen at the hospital.

### ILLINOIS

**Society News**—Dr Claude N Lambert Chicago addressed the Stephenson County Medical Society at Freeport March 16 on 'Fractures of the Hip'. At a meeting of the Lee County Medical Society in Dixon March 16 Dr Channing W Barrett, Chicago spoke on fibroids of the uterus. Dr Howard L Alt, Chicago discussed Trends in Treatment of Diseases of the Blood before the Sangamon County Medical Society in Springfield March 2. Dr Frank H Lahey Boston presented the annual lecture of the Springfield Medical Club March 14 discussing gastrointestinal surgery. Mr Charles C Thomas publisher of medical and scientific books and periodicals spoke at this meeting on William Beaumont.

### Chicago

**The Luckhardt Lecture by DeKruif**—On April 12 Paul DeKruif Ph D Holland Mich will speak at Mandel Hall of the University of Chicago delivering the Arno Benedict Luckhardt Lecture of the Phi Beta Pi Fraternity under the title 'Human Conservation'.

**Chicago's Health**—The general mortality rate for Chicago in 1938 dropped to an all time low of 97 deaths per thousand of population a decrease of 6 per cent from the rate of 103

for 1937 according to a recent report. A new low point was established for infant mortality when thirty-four deaths of babies under 1 year of age per thousand live births were recorded the maternal mortality rate dropped to 26 per thousand births which, it was stated, was 25 per cent fewer deaths than in 1937. The city's birth rate was 14.3 per thousand of population, an increase over the rate for 1937, when it was 13.8. The total number of births was 51,500. The daily attendance at clinics throughout the city was 2,000 and more than 100,000 persons voluntarily took blood tests in the health department's campaign against syphilis.

**Branch Meetings**—Dr Irving S Cutter addressed the Northwest Branch of the Chicago Medical Society March 17 at the Norwegian-American Hospital on 'State Medicine—Present Trends in This Country'. Discussion was opened by Drs Morris Fishbein, Editor of THE JOURNAL, Rollo K Packard and Nathan S Davis III. Dr John M Berger discussed Acute Intestinal Obstruction, Diagnosis and Conservative Management before the West Side Branch February 16 and Dr George F Thompson, the surgical treatment. Among others Dr J Arnold Barger, Rochester Minn, addressed the Jackson Park Branch February 16 on 'Constipation The Mechanism of Production and Management'. A symposium on genito urinary diseases dealing with infections of the upper urinary tract was presented before the Calumet Branch February 17 by Drs William J Baker Andrew J Sullivan and Dorris F Rudnick. At a meeting of the Douglas Park Branch February 21 Dr Harry A Gussin spoke on Proctology in General Practice. Dr Nathan S Davis III discussed Arteriosclerotic Heart Disease before the Southern Cook County Branch February 21.

### INDIANA

**County Survey of Syphilis**—Lake County launched a survey of syphilis January 3 under the direction of the U S Public Health Service the Indiana State Board of Health and the state medical society. The study aims to determine the number of cases in the county the number of those not receiving treatment and those receiving adequate care. With Drs Albert W Ratchiffe and Wendell C Kelly, Indianapolis, pathologist of the state department of health and chief of the state bureau of venereal diseases, respectively as consultants a county committee will carry out the work with the cooperation of physicians in the county.

### KANSAS

**Society News**—A symposium on acute otitis media was presented before the Sedgwick County Medical Society Wichita February 7, by Drs Ernest E Tippin, Orville C McCandless Charles L Woodhouse, Hal E Marshall, Earl D Carter Anthony F Rossitto and Ernest M Seydell all of Wichita. The Shawnee County Medical Society was addressed January 9 by Drs Orville R Clark on 'Acute Obstruction of the Ureter', Arthur D Gray, Making Lantern Slides from 35 Mm Film and Archibald J Brier Bacterial Sensitization in Relation to Other Allergic States. All are from Topeka. Dr Vern L Pauley, Wichita, discussed 'Renal Anomalies' before the Pratt County Medical Society, Pratt, January 27, Dr Newman C Nash, Wichita, spoke on 'Carcinoma of the Uterus'. Dr Lawrence S Nelson, Salina addressed the Clay County Medical Society January 18 on 'Modern Treatment of Fractures of the Neck of the Femur'. The Rice County Medical Society was addressed in Sterling January 26 by Dr Joseph V Van Cleave Wichita, on 'Fungus Diseases'.

### LOUISIANA

**Exhibit of Medical Prints**—Two hundred medical prints are on display in the library of the Orleans Parish Medical Society New Orleans representing a part of the collection of Dr Rudolph Matas. There are also photographs of the recent International Congress of Surgeons of which Dr Matas was president.

**Society News**—A symposium on recent advances in scleroderma was presented before the Orleans Parish Medical Society in New Orleans January 23 by Drs James K Howles George E Burch Jr Edward W Alton Ochsner and Michael F DeBakey. Dr Isidore S Kahn San Antonio Texas discussed Bronchial Asthma and Other Aspects of Allergy before the East Baton Rouge Parish Medical Society recently. At a recent meeting of the Pointe Coupee Parish Medical Society in Morganza a round table discussion was held on infections of the hand.

## MASSACHUSETTS

**Another Doctors' Orchestra**—The Boston Doctors' Symphony Orchestra is being formed under the direction of Nicolas Slonimsky, according to the *New England Journal of Medicine*. All physicians, dentists and medical and dental students who are interested should communicate with Dr. Julius Loman, Pelham Hall Hotel Brookline. Meetings began March 9 and will be held at Hampton Court Hotel, Brookline, every Thursday night.

**The Dunham Lectures**—Dr. K. Linderstrom-Lang of the Carlsberg Laboratory, Copenhagen, delivered the following lectures at Harvard Medical School, Boston:

- March 6, Micromethods for the Determination of Enzymes
- March 8, Distribution of Enzymes in Cells and Tissues
- March 10, Proteins and Proteolytic Enzymes

This series is presented under the Edward K. Dunham Lectureship for the Promotion of the Medical Sciences.

**Society News**—At a meeting of the Worcester District Medical Society in Worcester January 11 the speakers were Drs. Channing C. Simmons, Boston, on "Tumors of the Breast," and John T. B. Carmody, Worcester, "Injuries of the Peripheral Nerves". Dr. Raymond H. Goodale, Worcester, showed a bacteriologic exhibit and slides of nonepithelial tumors of the breast.—The Boston Medical History Club was addressed January 9 by Dr. Edwin B. Dunphy on "Development of Knowledge of Diseases of the Eye."

**New Position in Clinical Psychiatry**—Dr. John J. Slatery, acting superintendent of the state hospital at Medfield, has been appointed director of clinical psychiatry at the Boston State Hospital, a new position created by the legislature this year with an annual salary of \$3,300 and maintenance. The director will have charge of all medical activities at the hospital. Under the former system the assistant superintendent was medical director in addition to handling administrative work. Dr. Slatery graduated at the Boston University School of Medicine in 1929.

## MINNESOTA

**Changes in Health Officers**—Dr. John A. McIntyre has been chosen health officer of Owatonna, succeeding the late Dr. Jerome T. Smerish.—Dr. Dennis M. O'Donnell has been appointed health officer of Ortonville.

**Society News**—The Winona County Medical Society was addressed January 9 by Drs. Lewis G. Jacobs on "Therapy of Cancer of the Breast" and John A. Tweedy, both of Winona, on "Chronic Abdomen and Its Relation to the Abdominal Triad".—At a meeting of the Washington County Medical Society in January Dr. David Greth Gardiner, St. Paul, discussed bronchoscopy.

**Six Day Graduate Courses**—A series of six day graduate courses in special fields of medicine recently started at the Center for Continuation Study of the University of Minnesota, Minneapolis. Following is the schedule:

- Nervous and Mental Diseases March 13-18
- Diseases and Injuries of Bones and Joints March 13-18
- Diagnostic Roentgenology March 27-April 1
- General Surgery April 10-15
- Diseases of Blood and Blood Forming Organs April 17-22
- Obstetrics May 1-6
- Gastro-Enterology May 8-13

The programs are held in the special building devoted to graduate education for all professional fields. The building also serves as a residence hall for professional groups while they are attending the university. The tuition for each of the courses is \$25, and room and board may be secured for \$16. Physicians from outside of Minnesota are admitted on the same basis as residents. Further information may be obtained from J. M. Nolte, director, Center for Continuation Study, University of Minnesota, Minneapolis.

## MISSOURI

**District Meeting**—The Second Council District Medical Society will hold its second annual meeting at the Mark Twain Hotel, Hannibal, March 23. Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL*, will open the session by addressing a luncheon meeting of the chamber of commerce on "Frontiers of Medicine." Included in the scientific program will be:

- Dr. Joseph C. Jaudon, St. Louis: Hypoglycemia of Infants and Children
- Dr. Howard A. Rush, St. Louis: Diagnosis and Treatment of Chronic Undulant Fever
- Dr. Ernest Sachs, St. Louis: Present Status of Surgery of Brain Tumors and Some of the More Important Points of Diagnosis
- Dr. Francis A. Graham, St. Louis: Primary Cancer of the Lung

Speakers at the dinner will include Mr. Elmer H. Bartlesmeyer, St. Louis, executive secretary of the Missouri State Medical Association, Dr. James R. McLav, Kansas City,

president-elect of the state association, and Dr. Fishbein, whose subject will be "American Medicine and the National Health Program."

**Neuropsychiatric Meeting**—The Missouri-Kansas Neuro-psychiatric Society met in Kansas City February 15 with the following speakers:

- Dr. Edward T. Gibson, Kansas City: Thrombocytopenic Purpura with Hemorrhage and Softening of the Spinal Cord
- Dr. Arthur Graham Asher, Kansas City: The Heart Before and After Metrazol Convulsions
- Dr. Ferdinand C. Helwig, Kansas City: Studies of the Brain in Delayed Death Following Strangulation
- Drs. Benjamin Landis Elliott, Robert Lee Hoffmann and Caryl R. Ferris, Kansas City: A Case of Hypertensive Encephalopathy
- Dr. Norman Reider, Topeka, Kan.: Aphasia Following Exsanguination
- Dr. Harry Wilkins, Oklahoma City: Cerebellar Tumors: Their Diagnosis and Treatment
- Dr. Wallace Marshall Appleton, Wis.: Psychologic Observations with Reducation in a Case of Multiple Sclerosis
- Dr. Theodore A. Watters, New Orleans, La.: Fundamental Principles in Teaching Psychiatry
- Dr. Guy I. Witt, Dallas, Texas: Psychiatric Factors in Bromide Intoxication
- Dr. Lloyd H. Ziegler, Winnetka, Wis.: Aspects of the Basic Science Underlying Clinical Neurology and Psychiatry

**Annual Spring Clinic**—The St. Joseph Clinical Society will hold its eighth annual two day spring clinic March 28-29 at St. Joseph. There will be no registration fee. The speakers will include:

- Dr. Gershom J. Thompson, Rochester, Minn.: Transurethral Prostatic Resection
- Dr. Quintan U. Newell, St. Louis: Cancer of the Uterus
- Dr. Fred J. Taussig, St. Louis (round table discussion): Treatment of Septic Abortion and Coordination of Radium with Surgery in the Treatment of Cancer of the Cervix
- Dr. Willis C. Campbell, Memphis, Tenn.: Some Aspects of Surgery of the Hip Joint
- Dr. Heyworth N. Sanford, Chicago: Jaundice in the New Born
- Dr. August A. Werner, St. Louis: Effect of the Ductless Glands in Growth and Development
- Dr. Ralph A. Kinsella, St. Louis: The Pneumonias
- Dr. Walter C. Alvarez, Rochester, Minn.: Useful Hints in the Treatment of Indigestion
- Dr. Maurice C. Howard, Omaha, Neb.: Problems of Gastric Hemorrhage
- Dr. J. Arthur Myers, Minneapolis: Modern Methods in Diagnosis and Therapy of Tuberculosis
- Dr. Coyne H. Campbell, Oklahoma City: Practical Points in the Management of Neurotic Symptoms: Inhibitions and Anxiety
- Dr. Emanuel Grodinsky, Omaha: Pyogenic Infections of the Hand and Foot

Dr. Sanford will speak at the banquet on disturbances of blood coagulation. Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL*, will speak at a noon luncheon on "American Medicine and the National Health Program" and will deliver a public address on "The Social Aspects of Medical Care."

## NEW YORK

**Personal**—Dr. John F. McNeill, assistant superintendent of Matteawan State Hospital, Beacon, has been appointed superintendent of the Institution for Male Defective Delinquents at Napanoch, it is reported.—Dr. Henry W. Lattin, Albion, was recently the guest of honor at the annual reunion of the Society of the Erie Canal in Albion. Dr. Lattin received a master pilot's license in 1880 when he was 21 and for several years before studying medicine operated steamers between Buffalo and New York.

**Society News**—Dr. Allen O. Whipple, New York, addressed the Rochester Academy of Medicine March 1 on "Indications for and Results of Operations on the Spleen".—Dr. Willard M. Allen, Rochester, addressed the Rochester Pathological Society March 16 on "Types of Glandular Unbalance Frequently Seen".—Dr. Hugo Roesler, Philadelphia, conducted courses on heart diseases and demonstrations of fluoroscopic examination of the heart and aorta in Syracuse February 3-5 and 10-12 under the auspices of the Onondaga County Medical Society.—Dr. William Thalheimer, New York, addressed the Medical Society of the County of Nassau, Garden City, February 28, on "Prophylactic and Therapeutic Uses of Convalescent Measles and Convalescent Scarlet Fever Serums".—A Joint Committee in Specialties, comprising pathologists, radiologists, anesthetists and physical therapists has been formed in New York with Dr. Maxwell J. Fern, Brooklyn, as chairman and Dr. Madge C. L. McGinness, New York, as secretary. About 1,500 members of the Medical Society of the State of New York are represented.

## New York City

**Heart Association Honors Dr. Conner**—Directors of the American Heart Association recently voted to name an annual lecture established last year the Lewis A. Conner Lecture in honor of Dr. Conner, who was the first editor of the *American Heart Journal* and the first president of the association. The lecture will be given during the annual meeting in St. Louis May 12-13.

**Hospital News**—Parkway Hospital at 123 West One Hundred and Tenth Street has been taken over by the Italian Hospitalization Society to be operated for the Italian community on a nonprofit basis. The society was established in 1937—Dr Paul Liebeson, formerly director of the physico-medical section of the Physiologic Institute in the Allgemeines Krankenhaus, Vienna, has been appointed director of the physical therapy department of the Bronx Hospital.

**Dr Thygeson Succeeds Dr Wheeler at Columbia—Dr Dunnington Promoted**—Dr Phillips Thygeson, assistant professor of ophthalmology at Columbia University College of Physicians and Surgeons since 1936 has been promoted to a full professorship and appointed executive officer of the department of ophthalmology to succeed the late Dr John M. Wheeler. Dr Thygeson is 35 years old and graduated from Stanford University School of Medicine, Stanford University, Calif., in 1928. In 1931-1932 he held a National Research Council fellowship in medicine, working on trachoma at the Pasteur Institute in Tunis. Announcement was made at the same time of the promotion of Dr John H. Dunnington, associate professor of ophthalmology, to a full professorship. Dr Dunnington graduated from the University of Virginia Medical Department in 1915 and has been assistant director of the Institute of Ophthalmology, Presbyterian Hospital, since 1933.

**Courses for New Library Technicians**—The School of Library Service at Columbia University announces two new courses to be given during the summer session: one on microphotography and one on bibliographic and reference service in the medical sciences. The course on microphotography is designed to meet the need which libraries are now facing for skilled service in the production and use of microfilms as a substitute for the printed page or original documents according to the announcement. A new laboratory is now under construction for the course, which will consist of daily lectures and two laboratory periods a week. Registration for laboratory work is limited to twenty students to be selected from applications received before June 1. The course in medical library service will be given by Mr Thomas P. Fleming, librarian of the Columbia University Medical Library. If the response is satisfactory, it will be given regularly in the summer session and possibly also in the spring session after 1940. Besides reference and bibliographic work, it will include indexing, abstracting and reviewing medical journals.

#### NORTH CAROLINA

**Health Officer Honored**—Dr Joseph A. Morris Oxford, who recently retired as health officer of Granville County after about twenty years of service, was honored at a testimonial dinner February 16, given by the Granville County Medical Society, the Rotary and Kiwanis clubs and the Young Men's Club. Among the speakers were Dr Robert E. Fox, Raleigh, director of county health work for the state board of health and State Supreme Court Justice W. A. Devin. Raleigh. The group presented a watch to Dr Morris.

**Society News**—Dr William D. Hall, Raleigh, was elected president of the North Carolina Neuropsychiatric Society at its annual meeting at the Caswell Training School, Kinston, January 27. Dr William Ray Griffin, Asheville, was elected vice president and Dr Malcolm D. Kemp, Pinebluff, reelected secretary. Dr Joseph Stokes Jr., Philadelphia, addressed the Guilford County Medical Society, Greensboro, February 9 on 'Newer Advances in Infectious Diseases, Particularly Respiratory Diseases'. Dr Louis L. Hobbs Jr., Ridgeway, Pa., addressed the society January 5 on 'Gonorrhea: Its Clinical, Surgical and Pathological Aspects'. Dr William L. Kirby, Winston-Salem, addressed the Davidson County Medical Society, Lexington, January 11, on allergy in relation to dermatology.

#### OHIO

**State Board Officers Elected**—Dr Louis T. Franklin, Chillicothe, was elected president of the State Medical Board of Ohio at a meeting January 17. Dr John H. J. Upham, Columbus, was elected vice president and Dr Herbert M. Platter, Columbus, reelected secretary.

**Funds for Research on Dementia Praecox**—The National Committee for Mental Hygiene recently granted \$10,000 to Longview State Hospital, Cincinnati, to continue research on dementia praecox under Drs Esther Bogen Tietz and Douglas Goldman. The funds for this work were contributed by the Committee on Research on Dementia Praecox, founded by the Supreme Council, Scottish Rite Masons, North-eastern Jurisdiction.

#### OREGON

**Changes in State Health Board**—Drs Harvey A. Woods, Ashland, and Wendell H. Hutchens, Portland, were recently appointed new members of the state board of health and Drs Arthur W. Chance, Portland, and Norman E. Irvine, Lebanon, were reappointed. Dr Frank Mount, Portland, was elected president at a meeting January 10, Dr William J. Weese, Ontario, vice president, and Dr Frederick D. Stricker, Portland, executive secretary and state health officer.

#### PENNSYLVANIA

**Society News**—Dr Harold W. Jones, Philadelphia, addressed the Cambria County Medical Society, Johnstown, February 9 on 'Treatment of Diseases of the Blood'. Dr Harold L. Foss, Danville, addressed the Northampton County Medical Society February 17 at the Country Club of Northampton County on 'Treatment of Advanced Thyrotoxicosis'. Dr Joseph H. Barach, Pittsburgh, addressed the McKean County Medical Society, Bradford, January 17 on 'Nutritional Requirements in Diabetes'. Dr Murray M. Copeland, Baltimore, addressed the Washington County Medical Society, Washington, March 8 on 'Diagnosis and Treatment of Tumors of the Breast'.

#### RHODE ISLAND

**Special State Meeting**—Dr Rock Sleyster, Wauwatosa, Wis., President-Elect of the American Medical Association, addressed a special meeting of the Rhode Island Medical Society in Providence January 6 describing the development of American medicine and the work of the American Medical Association.

#### SOUTH CAROLINA

**State Society Entertains General Assembly**—The South Carolina Medical Association entertained the members of the general assembly and Governor Maybank at a luncheon at the Columbia Hotel, Columbia, January 25. Preceding the luncheon Dr Reginald Fitz, Boston, addressed the legislators on trends in medical education.

**State Pediatric Meeting**—Dr Daniel Lesesne Smith Jr., Spartanburg, was elected president of the South Carolina Pediatric Society at its annual meeting in Columbia January 23. Dr Lomita M. Boggs, Greenville, was elected vice president and Dr William Weston Jr., Columbia, secretary. Dr Martha M. Eliot of the Children's Bureau, U. S. Department of Labor, Washington, D. C., was the guest speaker on 'The Maternal and Child Health Program Under the Social Security Act'.

#### UTAH

**Annual Registration Due April 1**—All practitioners of medicine and surgery licensed to practice in Utah are required to register annually on or before April 1, with the Department of Registration and to pay a fee of \$3. If a licensee fails to reregister within from ninety days to six months after April 1 his license can be revoked, and if revoked it will be reinstated thereafter only on his paying the delinquent registration fees and an additional year's fee as a penalty.

#### WASHINGTON

**Personal**—About seventy-five friends and colleagues honored Dr Nils A. Johanson, Seattle, with a stag party February 9, on the thirtieth anniversary of the founding of the Swedish Hospital by Dr Johanson. It was also a farewell party to Dr Johanson, who is leaving for New Guinea.

#### WISCONSIN

**Pneumonia Control Committee Appointed**—At the request of the state board of health, the council of the State Medical Society of Wisconsin has authorized appointment of a committee to confer with the board on the formulation of a program for control of pneumonia. The members are Drs Arthur J. Patek, Milwaukee, Thomas J. Snodgrass, Janesville, and Alvin G. Koehler, Oshkosh.

**Society News**—Dr Armand J. Quick, Milwaukee, addressed the Racine County Medical Society, Racine, February 16 on 'Value of Prothrombin Determination and Hippuric Acid Test in the Study of Jaundice Patients'. Dr Stephan Epstein, Marshfield, addressed the Wood County Medical Society, Marshfield, February 21, on 'Differential Diagnosis and Treatment of Benign Skin Tumors'. Dr Elmer L. Sevringhaus, Madison, discussed endocrinology at a meeting of the Columbia-

Marquette-Adams County Medical Society in Portage February 21—Drs John L Emmett and Horton C Hinshaw, Rochester, Minn, addressed the Chippewa County Medical Society, January 24, on "Management of Urinary Calculi" and "Recent Advances in the Treatment of Pneumonia" respectively—Dr Reginald Jackson, Madison, addressed the Dane County Medical Society, Madison, January 10, on "Surgery of the Colon"

### WYOMING

**Annual Registration Due April 1**—All practitioners of medicine and surgery licensed to practice in Wyoming are required by law to register on or before April 1 with the secretary of the Board of Medical Examiners and to pay a fee of \$2.50. If a licensee fails to pay the fee within three months after April 1, his license can be annulled and if annulled it will be reinstated only on his paying the stated fee plus \$5 as a penalty.

### GENERAL

**Society News**—Dr L. Gerald Foster, Bay City, Mich., was chosen president of the Northwest Regional Conference at its session in Chicago February 12—Dr M. Pierce Rucker, Richmond, Va., was named president-elect of the South Atlantic Association of Obstetricians and Gynecologists at its first annual meeting in Charleston, S. C., February 11. Dr Robert E. Seibels, Columbia, S. C., became president and Dr Robert A. Ross, Durham, N. C., was reelected secretary. The association was organized a year ago at a meeting in Charlotte, N. C. The next meeting will be in Richmond, Va., in 1940.

**Pacific Coast Surgeons to Meet**—The annual meeting of the Pacific Coast Surgical Association will be held in San Francisco and Del Monte, Calif., March 28-31. The tentative program includes the following speakers:

Dr Frank Hinman, San Francisco: Cancer of the Prostate  
 Dr Maurice G. Kahn and Howard F. West, Los Angeles: Adenoma of the Pancreas  
 Dr Andrew A. Matthews, Spokane: Cancer of the Breast  
 Dr Thomas F. Mullen, San Francisco: Safeguarding the Unconscious Operative Patient  
 Dr Paul C. Flathow, Seattle: Advances and Retreats in Neurosurgery  
 Dr Millard T. Nelson, Tacoma: The Surgical Anatomy of Fistula in Ano

Dr Sumner Everingham, Oakland, is president of the association.

**Prevalence of Communicable Disease**—The U. S. Public Health Service recently announced that for the first six weeks of 1939, 20,877 cases of influenza were reported as compared with 18,420 for the corresponding period of 1938. The number of deaths from pneumonia for a group of cities with a total population of about 33,000,000 was 762 for the week ended February 4 as compared with a five year average of 992. Smallpox was reported to be unusually prevalent in Indiana (308 cases), Ohio (126), Iowa (117), Kansas and Minnesota (97 cases each), Oklahoma (94), Arizona (83), California (71) and Texas (65) during January. More than two thirds of the total number of cases (1,548) for the whole country occurred in these nine states. The total was about 65 per cent of last year's figures.

**Prize for Thesis in Obstetrics**—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons again offers its annual Foundation Prize for a thesis. The prize this year will be \$100. Those eligible to compete are (1) interns, residents or graduate students in obstetrics, gynecology and abdominal surgery, and (2) physicians who are actually practicing or teaching obstetrics, gynecology or abdominal surgery. Competing manuscripts must be presented in triplicate under a nom de plume to the secretary of the association before June 1, must be limited to 5,000 words and such illustrations as are necessary for a clear exposition of the thesis and must be typewritten (double spaced) on one side of the sheets, with ample margins. The successful thesis must be presented at the annual meeting of the association in September without expense to the association and in conformity with its regulations. For further details address Dr James R. Bloss, Secretary, 418 Eleventh Street, Huntington, W. Va.

**Pacific Science Congress in San Francisco**—The sixth Pacific Science Congress will be held in California July 24 to August 12 under the auspices of the National Research Council. Sessions will be held at the University of California, Berkeley, Stanford University and in 'Pacific House' on the grounds of the Golden Gate International Exposition in San Francisco. The theme of this congress will be the present state of knowledge of Pacific problems and methods by which

that knowledge may be most profitably enlarged" and the program will be arranged as a series of symposiums. Among them are one on 'Communicable Diseases of the Pacific Area, Origin, History, Distribution, Tropical Medicine' and one on 'Nutritional Problems of the Pacific Area'. Information about the congress may be obtained by addressing the secretary general, Roy E. Clausen, Ph.D., Room 205 Hilgard Hall, University of California, Berkeley. The last previous congress in this series was in Vancouver and Victoria, B. C., in 1933.

**Physicians' Art Exhibition**—The American Physicians' Art Association will hold an exhibition of art by members at the City Art Museum of St. Louis, May 14-30. Works in any of the fine or graphic arts are eligible. The privilege of exhibiting works is open to members of the American Physicians' Art Association, to honorary members and to other physicians, dentists and doctors of philosophy, by invitation. All works submitted must be appropriately framed. Foreign exhibitors, however, might well have their art pieces framed in this country as picture frames are taxed on entrance whereas unframed pictures are not taxed. Not more than five works will be accepted from any one entrant. The hanging fee is one piece \$2, two pieces \$4, three pieces \$5 and five pieces \$7. The check should be made out to Dr. R. W. Burlingame, treasurer, and mailed with entry notice to Miss Dorothy Hetlage, City Art Museum, St. Louis, Mo. No entries will be received after 5 p. m. May 1. Prizes, medals and cups will be awarded.

## Government Services

### National Cancer Institute Buys Radium

The National Cancer Institute purchased in December 95 Gm of radium valued at \$200,000. The radium supply will be lent to hospitals and clinics for treatment of cancer. An institution that borrows the radium must take the responsibility of transporting it from the Bureau of Standards and back again for periodic testing; must store it properly while using it and must insure it against loss and damage. According to the *Health Officer*, personnel and equipment of the borrowing institution must meet standards equal to those established by the American Board of Radiology for the safe use of radium. According to the terms of the loan preference in use of the radium will be given to persons unable to pay for treatment.

### Examination for Medical Officers in Veterans' Administration

The U. S. Civil Service Commission announces an open competitive examination for the position of associate medical officer in the Veterans Administration with a salary of \$3,200 a year. Competitors will not be required to report for written examination but will be rated on the extent of their education and on their experience and fitness. If conditions permit an oral examination will be given to a sufficient number of competitors in the order of their standing to meet the needs of the service. Applicants must not have passed their fortieth birthday on the closing date for applications. They must have graduated from a recognized medical school since May 1, 1934 and must have completed at least one year of internship. Persons now serving internships may apply but cannot be appointed until proof of satisfactory completion of the internship is furnished. Detailed information and application forms may be obtained from the secretary of the U. S. Board of Civil Service Examiners at any first class postoffice, from the commission at Washington or from the civil service district office at any of the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, C. Z. and San Juan, P. R. The closing date is April 10 except from the following states for which the date is April 13: Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming.

### CORRECTION

**Evanston Hospital's Necropsy Percentage**—Evanston Hospital, Evanston, Ill., should have been included in the list of approved internship hospitals having over 70 per cent necropsies on page 924 of the *Hospital Number of This Jour* N. L. March 11 1939. Its record was 81.2 per cent.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Feb 18, 1939

#### Epidemic Nausea and Vomiting

In 1935 Danish writers described under the name of epidemic nausea what appears to be a new disease. They meant by nausea not simply the feeling of sickness but all the symptoms of sea sickness. In 1936 the disease was first observed in England in a boarding house for girls at the seaside resort of Broadstairs by the pediatrician Reginald Miller and M. O. Raven. It affected fifty-two of 117 residents. Miller described the disease in the 'Proceedings of the Medical Officers of Schools Association'.

The chief symptoms are vomiting, nausea, giddiness and diarrhea. Vomiting occurred in forty-two of the fifty-two cases. It was often explosive and unexpected, in many cases it was a single vomit only and tended to occur on the patient's waking in the morning. In no case did the sickness last more than six hours. Nausea without vomiting occurred in ten cases and giddiness in thirteen. Diarrhea did not occur. The disease seemed clearly of the same type as the Danish epidemics but there were certain differences. In the first Danish epidemic mild diarrhea with mucus in the stools occurred toward the end of the illness in twelve of forty-seven cases. In the second also diarrhea occurred, but it is particularly mentioned that no blood or mucus was present in the stools. Fever was rare and always slight. Recovery was complete in forty-eight hours. The epidemic affects persons of all ages but has a tendency to spare infants. A characteristic is the high proportion of a population attacked (from 33 to 75 per cent). The cause is obscure. Miller regards it as an borne and probably infectious.

Other epidemics have been observed in England. The last was reported by J. D. Gray (*Brit. M. J.* 1:209 [Feb. 4] 1939). It occurred in a country district (South Hampshire). In addition to the vomiting, frontal headache, diarrhea, pyrexia (the temperature always below 100 F) and occasionally bradycardia were observed. In a girls' school forty-five of eighty-two pupils were attacked and at the same time the disease was prevalent in the surrounding country. No organisms known to cause gastroenteritis were found. The greatest argument against food or water contamination was the type of spread in families or institutions from the first patient. Thus two of the school children went home and two days later both parents contracted the disease. Some dysentery in an institution might be confounded with epidemic vomiting but is distinguished by its much greater severity.

#### Thrombosis Following Injection of Iopax (Uroselectan)

Though mishaps occur from time to time in the injection of veins, a case in which the surgeon has to defend himself against a charge of negligence has only now arisen. A woman aged 52 was given an injection of iopax (uroselectan) for a ray examination of the kidneys by the house surgeon of the Kent and Canterbury Hospital in December 1934. He first tried to inject the substance into the veins of the arms but could not do so because these veins were not visible. He then found a suitable vein in the left leg which he injected. This was the only occasion on which he saw the woman. A roentgenogram taken seven minutes after the injection clearly showed the pelvis of the kidney. She alleged that the injection was so negligently performed that some of the fluid escaped into the tissues around the vein and gave rise to phlebitis, the

consequence of which was disability likely to be permanent. She suffered much pain and when she returned home had to go to bed, where she remained under medical care for six months. In his evidence the surgeon stated that he had successfully injected this drug on many occasions. When he injected the plaintiff's vein the needle was in the vein. Pain was commonly caused, but he had no recollection of any unusual complaint on her part. Medical evidence was given that thrombosis might result when the injection was made into the vein and that some people had a tendency to thrombosis, the reason for which was not known. The judge said that there was no evidence that the surgeon had done anything that he ought not to have done or that there was any lack of skill on his part. He therefore gave judgment for the defendant.

#### The British Heart Journal

A new periodical, the *British Heart Journal*, has been inaugurated by the British Medical Association. It is under the control of an editorial board of cardiologists. In a foreword Sir Thomas Lewis states that the Cardiological Society of Great Britain has decided to have a journal of its own. He points out that there is no stronger tradition of work on the heart than the British, which begins with the incomparable Harvey and passes through Lower, Hales, Heberden, Stokes, Mackenzie and other clinicians as well as the physiologists Gaskell and Starling. The *Journal* is to be published quarterly and the subscription fee is \$5 to members of the society and \$6 to nonmembers. The January issue, which has just been published, contains 'Some Disturbances of the Rhythm of the Heart' by John Cowan, 'Digitalis in Heart Failure with Normal Rhythm,' by C. J. Gavey and John Parkinson, 'Chest Leads in Clinical Electrocardiography,' by Paul Wood and Arthur Selzer, 'A New Sign of Left Ventricular Failure,' by Paul Wood and Arthur Selzer, 'The Significance of Electrocardiograms Showing a Second Positive Wave of QRS in Lead III,' by A. A. Fitzgerald Peel, and 'Some Notes on the Cardiac Club,' by John Cowan and others.

#### Blood Transfusion During War

Several years ago a committee composed of Profs. A. Gossset, E. Levy-Solal and Arnault Tzanck was appointed to elaborate a technique for blood transfusion on a large scale which might be applied in case of war. This committee submitted its report at

Fig 1—Henry Jouvet apparatus

the February 7 meeting of the Académie de médecine of Paris. The recent experience of countries at war in Europe and Africa has shown that no matter how thorough the prewar preparations for transfusions have been they are usually found to have been inadequate. At least 60 liters of blood must be ready for imme-

diate use in each of the main centers and subcenters. This means that only conserved refrigerated blood can be considered as practicable, because of the necessity of transporting it to the first aid stations. This amount of blood must be furnished by noncombatants relatively far behind the front and ought not to be furnished either by soldiers or by hospital personnel. The

Fig. 2—Tzanck three way distributor

blood should be ready to be used, having been conserved in simple sterilized flasks, such as are employed for conserving ordinary serum. All laboratory examinations are made at the chief or subcenters, each donor giving from 300 to 500 cc, which is collected in a 1,000 cc flask. The apparatus which the committee recommended is that of Henry and Jouvet,

Fig. 3—Apparatus for oxygenation of blood

which delivers 1 cc of blood at each revolution. This enters a special chamber, where it mixes with 1 drop of a 9 per cent solution of sodium citrate and 1 Gm of dextrose. Instead of the Henry-Jouvet apparatus, the Tzanck three way distributor can be used, in which 1 cc of citrated serum is mixed with every 10 cc of blood. Although not absolutely necessary, oxygenation of the blood is of great aid, because it indicates absence of infection if the blood retains its red color. After 1,000 cc

Fig. 4—Distribution into ampules

of citrated blood has been collected, the flask is inverted and its contents are allowed to run into four flasks each with a capacity of 250 cc. Each 250 cc flask is placed in a cardboard box, well covered by corrugated paper, so that the blood will retain its low temperature after it is taken out of the refrigerator. For transportation an airplane or fast motor vehicle with refrigeration equipment is to be preferred to a train and six flasks are placed in a single corrugated cardboard box. Instead of a simple 250 cc flask, one with a marked constriction at the center is now being used in the Spanish armies to eliminate, so far as possible, shaking of the blood during its transportation to the front. As to injection, the citrated blood is allowed to flow by gravity into the

vein of the recipient through a sterilized rubber tube and needle, which traverse a dish filled with water at 39 or 40 C. At least six mobile laboratory units should be available, which can function in some city well behind the front. To make possible the securing of 60 liters of blood, the unit should be established in a community where at least 30,000 potential donors can be examined. Such units ought really to be established in the larger cities in peace time, so that they would be ready to function when war broke out. This has already been done in France, each civilian donor being given an identity card after the necessary laboratory examinations.

The personnel of the chief and secondary centers ought to be provided for in peace time. The physician in charge of the center, the laboratory head and the assistants should be persons who are exempt from mobilization and who have had ample experience in the collection of blood for transfusion purposes. The slightest error made by a technician may be followed by disastrous results. Although citrated conserved blood is indispensable when large quantities are needed, one must not overlook the fact that noncitrated blood, i. e. pure blood, is to be given preference when available or when transportation of citrated blood to the front is impossible. Technicians ought to be trained during peace time so as to be available

Fig. 5—Package for transportation

Fig. 6—A six ampules ready for transportation. B hourglass ampule, used to prevent shaking. C bowl for reheating blood.

in war. At the Paris center more than 150 technicians have been given a thorough course of instruction.

A Proposed Health Record for Every Citizen

Several years ago the minister of public health gave orders that a study be made as to the practicability of every person's possessing a book in which all illnesses and injuries are to be recorded, so that a physician who is called to treat a man, woman or child will immediately have at his disposal much valuable information as to the previous medical history. Objec

tions were raised that the recording of venereal infections would be resented, hence but little progress was made until recently, when the present minister of public health appointed a physician who has had a large experience in the French colonies to study the advisability of a health book, or "carte de sante," which would be obligatory for every person in European France and its colonies. It has been proposed to eliminate the previous objection to the recording of venereal disease by the use of some secret initials or nomenclature which can be interpreted only by physicians.

### The Genetic Aspect of Diabetes Mellitus

Extensive studies of the hereditability of diabetes mellitus in an unselected group of twins heretofore have not been available. Research is now being carried on by Hildegard Then-Berg at the Kaiser-Wilhelm Institute of Genealogy and Demography, Munich. Then-Berg began with a basic material of some 85,000 persons with diabetes mellitus, among whom there were 411 pairs of twins, and she has already studied 147 of these pairs. Forty-six were enzygotic and eighty-seven were dizygotic, the exact zygotic origin of two pairs was open to question, and the remaining twelve pairs had to be eliminated from the study, since they presented no diabetes mellitus whatever. The author tries to observe all the twins personally. She examines the urine and blood sugar and in most cases performs a blood sugar tolerance test. A pair of twins is termed "absolutely concordant" if each twin of the pair was at the time of examination suffering from a manifest diabetes mellitus with demonstrable excretion of sugar in the urine. If one twin, although not manifestly ill and passing normal urine, shows by the tolerance test that the insular system is unable to metabolize a tolerance test dose of twice 20 Gm. of dextrose, the pair is termed concordant according to tolerance. A group termed discordant according to tolerance is also distinguished, among these the dextrose tolerance test of the twin who is not manifestly ill reveals a normal blood sugar curve which (after fasting) is not above 120 mg. per hundred cubic centimeters. This curve furthermore at its peak does not exceed 180 mg. per hundred cubic centimeters. In the second tolerance test with dextrose (after forty minutes) it shows no further rise, and finally, after 120 minutes it returns to its normal value. Termed probably discordant are those pairs of twins who could not be examined because they had already died but who according to the histories of their cases, appear not to have been affected with manifest diabetes mellitus.

According to the figures thus far elicited from these carefully performed studies seventeen pairs of enzygotic twins were absolutely concordant, thirteen were concordant according to tolerance, six were discordant according to tolerance and ten were probably discordant. Nine pairs of dizygotic twins were absolutely concordant, nine were concordant according to tolerance, thirty-two were discordant according to tolerance and thirty were probably discordant. Then-Berg established an interesting correlation between manifest diabetes mellitus and age. It was found that almost without exception after the age of 43 the enzygotic pairs were all concordant, and not one discordant pair was to be observed above this age limit.

It is therefore proved on the basis of a large group of twins that diabetes mellitus is purely hereditary. It is possible, however, with the examination methods available, to establish certain proof of the inherited inferiority only if the twins have passed the forty-third year of life.

### Immediate Resection in Cases of Perforating Gastric Ulcer

The therapeutic results with freely perforating gastric and duodenal ulcers have been considerably bettered in the last fifty years. The mean mortality in earlier times was as high as from 60 to 90 per cent, but in the last decade it has decreased to below 20 per cent. Information on this topic has recently been compiled by Dr. Junghanns at the surgical clinic of Frankfurt University (Professor Schmieden's clinic). Whereas formerly only 16 per cent of the patients came to operation during the first six hours and 54 per cent during the first twelve hours following perforation, in the last ten years 75 per cent came to operation during the first six hours after perforation and 95.4 per cent within the first twelve hours.

Moreover, changes in the surgical technic have made possible a more favorable prognosis. Immediate gastric resection has supplanted the older palliative interventions (suturing over, with or without gastro-enterotomy). In the last ten years there were performed at the Schmieden clinic sixty gastric resections (second method of Billroth), with a mortality of 67 per cent, and fifty-one palliative operations, as mentioned, with a mortality of 39.2 per cent. More favorable results can be obtained if the general condition, the circulation in particular, is correctly evaluated. The time elapsed between perforation and intervention is therefore not the decisive factor. Immediate resection has the additional advantage of leading to essentially more favorable permanent results. Follow-ups disclosed that 95.8 per cent of the patients who submitted to resection were completely fit to work, whereas only 67.8 per cent of those who had undergone palliative operations had regained complete working capacity.

### Indications for Arteriography and Ventriculography

The neurosurgeon Professor Tonnis recently discussed the indications for arteriography and ventriculography before the Berlin Medical Society. X-ray examination by means of ventriculography has become an important procedure for neurosurgeons, despite the fact that a mortality of 8 per cent is still to be reckoned with. A great many brain tumors and other cerebral disorders could not be diagnosed without ventriculography, and conditions of this sort incorrectly diagnosed almost invariably result in a fatal outcome. Insufflation of the ventricle, which is generally done after suboccipital puncture, makes possible an exact evaluation of the site, size and type of any tumor relating to the ventricles. Cases in which a considerable elevation of cerebral pressure is present are unsuitable for ventriculography. Consequently, arteriography has come increasingly to the fore. In the latter method the exposed internal carotid is injected with thorium dioxide sol. In this way information with regard to tumors of the medial or anterior cranial fossae is elicited without exposing the patients to the danger of increased cerebral pressure. Tumors of the temporal lobe can be visualized readily by this means. Since the region of the posterior cranial fossa is not supplied by the internal carotid artery, tumors arising there cannot be diagnosed by arteriography. The method is particularly valuable because it not only makes possible conclusions with respect to the site of the tumor but shows the source of the neoplasm's vascular supply as well. Since by arteriography tumors can be differentiated according to their richness or poverty in vasculature, accurate diagnoses with regard to their histologic structure may be made. The procedure is of special importance for the diagnosis of meningiomas and multiform neoplasms. It also aids in the recognition of brain abscesses and subdural hematomas. Ventriculography as well as arteriography should be done only if the indication is definite and then only by a specialist skilled in the technic.

## A Clinical Study of Angina Pectoris

Dr M Semerau-Siemianowski, professor at Warsaw University, and Dr H Rasolt have published a study of angina pectoris based on 518 patients seen by Professor Semerau-Siemianowski in his private practice and on eighteen patients admitted to the St Lazarus Hospital in Warsaw. These 536 patients were observed between 1925 and 1933. In 1936 a follow-up letter was sent to every patient. The small number of patients admitted to the hospital in proportion to those seen in private practice agrees with the records of others.

The ratio between the number of patients with angina pectoris and all patients over 20 with cardiovascular disorders consulted during the same period was 518 to 4373, or 12 per cent. White in America found the percentage to be 12.5, Koller in Germany 8.1, and J Pawinski in Poland 5.2. According to Cabot, cardiovascular disease occurs in 38 per cent of all patients, then the actual incidence of angina pectoris in Poland could be estimated at about 4.6 per cent of all other diseases. The incidence of angina pectoris obtained in the same way from the statistical data of White is 4.75 per cent, while in the former (1913) Polish report of Pawinski it was but 2.9. Thus there was an increase in the incidence of angina pectoris in Poland during the last two decades. Furthermore, this increase was more marked in the later four years of the period considered 1929-1932, than in the former four years, 1925-1929. This applies particularly to the organic forms of angina pectoris. Professor Semerau-Siemianowski supposes that this rise in the angina pectoris incidence may be due partly to social factors.

According to Professor Semerau-Siemianowski there are two main types of this disease, the organic and the functional. In the former he has distinguished two main forms: the acute form consists of only one variety, the cardiac infarction. The chronic form has three varieties: coronalgia, attributed to changes in the main coronary arteries and occurring with the clinical picture of angina of effort, myocardialgia, attributed to diffuse changes of the minute coronary arteries, followed by small necrotic foci in the myocardium and characterized by slight attacks of cardiac pain occurring at rest and by coexisting signs of heart failure, and aortalgia, due to pathologic changes in the aorta. There are four varieties of so-called functional angina pectoris: (1) the neurotic variety, (2) reflex angina pectoris, the attack being provoked by disorders in other organs, e.g. by flatulence or gallbladder diseases, (3) toxic angina, attributed to nicotine, caffeine or such endogenic factors as gout and endocrine disorders, and (4) anemic angina pectoris, caused by myocardial ischemia without any coronary disease.

The incidence found for these varieties of angina pectoris was coronalgia 52.7 per cent, aortalgia 11.5 per cent, myocardialgia 6.8 per cent and cardiac infarction 7.7 per cent. The organic forms of angina pectoris were found in 78.7 per cent of cases and the functional forms in 21.3 per cent. Neurotic angina pectoris was found in 11.5 per cent of cases, reflex angina in 4.7 per cent, the toxic form in 2.3 per cent and the anemic form in 2.8 per cent. The figures obtained for the incidence of the organic form agree strikingly with those obtained by some foreign authors. Gallavardin found organic forms in 78 per cent of his cases, White in 74 per cent and Lian in about 80 per cent. This comparison brought out that in at least three fourths or four fifths of cases angina pectoris has an organic substratum: cardiac infarction being present in every one of ten cases of organic angina pectoris. In 25.7 per cent of the cases of chronic organic angina a combination of the organic fundamental disease and functional factors was present. Coexisting functional factors were due to a reflex mechanism in 14.6 per cent of the cases of organic forms, to toxic influences in 7.1 per cent and to psychoneurotic agents in 4 per cent.

Angina pectoris begins most commonly in the fifth and sixth decades, and in the later decades the incidence decreases. This is in strong contrast to the age incidence of pathologic changes of the coronary vessels observed at necropsy, for these changes increase with the age of the subject. The authors then imply that an important cause of angina pectoris might be such agents as intense professional work and the irritations of everyday life as well as sympathetic and endocrine disorders arising at the age of about 50.

Angina pectoris has a strong tendency to affect Jews, the incidence being nearly four times greater in Jews than in others. Women were affected in only 12.5 per cent of all cases. The majority of the subjects were well-to-do and intelligent.

Heredity is likely to play an important part in the genesis of angina pectoris. A history of cardiovascular diseases in parents or in kinsfolk was found in 41.6 per cent of all cases of angina.

Syphilis is held to be the cause in from a fourth to a fifth of all cases.

The role assumed by nicotine in producing angina pectoris has been overrated. Although there might be some individuals particularly sensitive to smoking, no parallel was found between the amount of smoking and the seriousness of the condition. The same is to be said concerning the influence of alcohol.

The duration of the disease from the onset of symptoms to the first consultation did not exceed five years in about 50 per cent of the cases. The average duration until the first consultation was from three to four years. According to the 140 replies to the inquiry, the average time of survival was eight years after the onset of the disease. Death occurred at the average age of about 64. It occurred most frequently within the first year of the disease, afterward the mortality rate decreased gradually until the ninth year, after which the chances for survival lessened.

In 83.1 per cent of cases the pain was located behind the sternum; most commonly it was felt transversely and in rare instances longitudinally. In 12.1 per cent of cases the pain was located far from the precordial region. The pain was accompanied by anxiety in 37.5 per cent.

The anginal attack could be provoked by physical efforts in 68 per cent of all cases, by emotional disturbances in 37 per cent and by heavy meals in 20 per cent.

Normal systolic arterial pressure was found in 31.9 per cent of cases. It was lowered in 17.1 per cent and elevated in 51 per cent. The average systolic pressure of all the cases of angina pectoris was 168.1 mm. In females this average systolic pressure was higher than in males: 183 against 166 mm. The average diastolic pressure was 99.1 mm. The authors emphasize the considerable difference between the average systolic and diastolic pressures.

As shown by an x-ray examination, structural changes in the aorta were present in 36 per cent of all cases. There was evidence of sclerosis of the peripheral arteries in about 60 per cent of the cases. Intermittent claudication coexisted in 2.8 per cent and it occurred most frequently in tobacco smokers.

## Marriages

---

ARTHUR SUMNER BRINKLEY, Richmond, Va., to Miss Constance Elizabeth Brown of Greenwich, Conn., January 3.

WILLIAM EDWARD BARFIELD, Atlanta, Ga., to Miss Ellen Theresa Ryan of Savannah, Dec 23 1938.

WILLARD N. BLOVE, Oak Park, Ill. to Miss Mabel Lillian Wingard of Chicago, February 11.

STEPHEN TRENT BARNETT JR. to Miss Josephine Meador, both of Atlanta, Ga., in February.

SAMUEL TAMARKIN to Mrs. Ida Broida, both of Youngstown, Ohio, recently.

## Deaths

**James Carroll Flippin** \* Charlottesville, Va. University of Virginia Department of Medicine, Charlottesville 1901 member of the House of Delegates of the American Medical Association 1934-1938 and in 1936 was elected a member of the Council on Scientific Assembly for a term of five years to end in 1941, dean since 1924 and professor of internal medicine since 1915 at his alma mater, and at various times demonstrator of histology and pathology adjunct professor of bacteriology and professor of clinical medicine past president of the Medical Society of Virginia, aged 61 died, February 16, of heart disease

**William Gray Ricker** \* St Johnsbury Vt Johns Hopkins University School of Medicine, Baltimore, 1904, member of the House of Delegates of the American Medical Association 1925-1928, 1930, 1932-1934 past president and secretary of the Vermont State Medical Society, past president of the New England Medical Council, at one time chairman of the Vermont Department of Public Health, member of the American Academy of Ophthalmology and Oto-Laryngology and the New England Ophthalmological Society, aged 62, died, February 28

**Harry Philip Cahill** \* Boston, Harvard University Medical School, Boston, 1911, assistant professor of otology at his alma mater and the graduate school, member of the American Academy of Ophthalmology and Oto-Laryngology, American Otological Society and the New England Otological and Laryngological Society, served during the World War, surgeon to the Massachusetts Charitable Eye and Ear Infirmary, aged 54 died, January 15, in the Peter Bent Brigham Hospital of cerebral hemorrhage, hypertension and cerebral thrombosis

**P Maxwell Foshay** \* New York University of Pennsylvania Department of Medicine, Philadelphia 1891, member of the House of Delegates of the American Medical Association, 1902-1903 vice president of the Mutual Life Insurance Company of New York, aged 71, died, January 26 at the Mount Sinai Hospital, Montclair, N J, of coronary sclerosis and myocarditis

**Joseph Thomas Hornback**, Nevada, Mo Kansas City Medical College 1896, member of the Missouri State Medical Association, formerly secretary of the Vernon-Cedar Counties Medical Society, at various times county coroner county health officer and treasurer of the school board, aged 66, died, Dec 31, 1938, of cerebral hemorrhage

**Inman Williams Cooper** \* Meridian Miss University of Tennessee Medical Department, Nashville 1903 past president of the Mississippi State Medical Association, served during the World War, formerly member of the state board of health aged 56, died, January 26, at the Rush's Infirmary of cirrhosis of the liver

**Chester Dale Christie** \* Cleveland Western Reserve University School of Medicine Cleveland 1913, assistant clinical professor of medicine at his alma mater, served during the World War, aged 52, on the staff of the Lakeside Hospital, where he died, January 27 of coronary thrombosis

**Frank Guillemont** \* Niagara Falls, N Y, Western University Faculty of Medicine London, Ont, Canada, 1893, on the staff of the Niagara Falls Memorial Hospital, president of the board of managers, Niagara Sanatorium, Lockport, aged 66 died, Nov 1, 1938, of coronary occlusion

**George Emmet Hart**, Lyman, Neb Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1906 member of the Nebraska State Medical Association, aged 62, died Nov 6 1938 in the West Nebraska Methodist Episcopal Hospital, Scottsbluff, of lobar pneumonia

**Arthur Thomas Paull**, Flint, Mich, Detroit College of Medicine 1909, member of the Michigan State Medical Society, served during the World War, aged 61 died, Dec 11, 1938 in the Women's Hospital of heart disease and pneumonia following influenza

**Justin E Rowland**, South Euclid Ohio Homeopathic Hospital College Cleveland, 1891, past president of the county school board, aged 74, died Dec 9, 1938 in the Huron Road Hospital, East Cleveland, of coronary thrombosis

**Willis F Huntsman** \* Lexington, Tenn, University of Tennessee Medical Department Nashville, 1900 past president of the Henderson County Medical Society, aged 70, died, Dec 22, 1938 of coronary occlusion

**Edward J Higgins**, Joliet, Ill, Northwestern University Medical School, Chicago, 1901, member of the Illinois State Medical Society, city health officer, aged 67, died, Dec 24, 1938 of coronary thrombosis

**Alfred Ephraim Reiter**, Melcher Iowa, State University of Iowa College of Medicine, Iowa City, 1901, member of the Iowa State Medical Society, aged 61, died, Dec 8, 1938, of cardio-renal vascular disease

**David Wells Register**, Columbia, S C, Atlanta Medical College 1914, member of the Medical Association of Georgia, aged 52 was found dead, Dec 22, 1938, of carbon monoxide poisoning, self administered

**James John Conlon** \* Cuyahoga Falls, Ohio, University of Michigan Homeopathic Medical School, Ann Arbor, 1915, aged 54 died, Dec 2, 1938, in the City Hospital of carcinoma of the stomach

**David H Kogan**, Philadelphia Universität Bern Medizinische Fakultät, Switzerland, 1919, on the staff of the Mount Sinai Hospital, aged 49, died, Nov 23, 1938, of cerebral hemorrhage

**Jordan Lally** \* Long Island City, N Y, University of Vermont College of Medicine, Burlington 1921, aged 45, died, Nov 26 1938 in the New York Hospital of heart disease

**George William Woodnick**, Los Angeles, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1906 aged 62, died, Nov 10, 1938

**Jones Riley McMillan**, Cardington, Ohio Cincinnati College of Medicine and Surgery, 1895, aged 88, died, Dec 13, 1938 of arteriosclerosis and chronic interstitial nephritis

**John B Keaggy**, Pittsburgh, Jefferson Medical College of Philadelphia, 1875, member of the Medical Society of the State of Pennsylvania aged 86, died, Nov 6 1938, of uremia

**Walter Emil Frank** \* St Louis, Washington University School of Medicine, St Louis, 1910 aged 52, died, Dec 2, 1938 in the Lutheran Hospital of carbuncle on the neck

**William Otwa Lee**, Danville Va University College of Medicine Richmond, 1903, aged 59, died, Dec 31, 1938, in the Memorial Hospital of cancer of the pancreas and liver

**John Edwin Dearden** \* New York University of the City of New York Medical Department, 1891, aged 75, died, Dec 10 1938, in the Misericordia Hospital of pneumonia

**Hubert Lewis Hollenbeck**, Los Angeles, State University of Iowa College of Medicine, Iowa City, 1900, aged 62, died, Nov 18, 1938, of tuberculous bronchopneumonia

**Ezekiel E Gillilan**, Columbus, Ohio, Kentucky School of Medicine, Louisville 1893, aged 66, died, Dec 28, 1938, in the White Cross Hospital of heart disease

**Szabo Serge Kalman**, Roseville, Calif, Univerzita Komenského Fakulta Lekarska, Bratislava, 1921, aged 42, died, Nov 21 1938, of coronary occlusion

**William John Sweasey Powers**, New York, Cooper Medical College San Francisco, 1904, aged 63, died, Dec 12, 1938 of acute dilatation of the heart

**John Bernhard Egts**, Delphos, Ohio, Homeopathic Hospital College, Cleveland, 1885, formerly city health commissioner, aged 87, died, Nov 5, 1938

**Franklin Charles Hull**, Twining, Mich, Saginaw Valley Medical College, Saginaw Mich, 1901, aged 59, died, Dec 9, 1938, of cerebral hemorrhage

**Wellford B Lorraine**, Richmond, Va, Hahnemann Medical College and Hospital, Chicago, 1906, aged 58, died, Nov 12, 1938 of cerebral hemorrhage

**John Robert Pate**, Los Angeles Central College of Physicians and Surgeons, Indianapolis, 1897, aged 71, died Nov 5, 1938 of coronary occlusion

**Charles Jeremie Coulombe**, St Justin Que Canada, Victoria University Medical Department, Coburg, Ont, 1872, aged 92, died Dec 1, 1938

**Robert E La Rue** \* Erie, Ill Louisville (Ky) Medical College, 1894, aged 64, died suddenly, Dec 6, 1938, of coronary sclerosis and myocarditis

**Robert A Blackburn**, Glendale Calif, Hahnemann Medical College and Hospital, Chicago 1886, aged 82, died, Nov 24, 1938 of acute nephritis

**William Randolph Pettit** \* Brooklyn, Long Island College Hospital, Brooklyn, 1901, aged 66 died, Nov 11, 1938, of cerebral hemorrhage

**Carl Huston Wright**, Yorktown, Ind Medical College of Indiana, Indianapolis, 1903, aged 60, died, Nov 25, 1938 of angina pectoris

**Harry Sutphin Hatch**, Madison, Ind, Pulte Medical College Cincinnati, 1892, aged 71, died, Nov 29, 1938, of cerebral hemorrhage

### THE CHEMIST IN THE MEDICAL LABORATORY

*To the Editor* —The place of the chemist in a clinical laboratory cannot be evaluated either by a busy physician or by a chemist without experience in laboratories. The problems of each laboratory are different.

From personal experience I feel that the chemist undervalues the participation of the physician in his laboratory work and that few physicians quite understand the purpose of the chemist. The less participation on the part of the physician in the clinical laboratory, the better for the essential work of the laboratory. At the same time, the fewer times the chemist is called on for his opinion as to whether a given determination is normal or pathologic, the better for the patient and the hospital. A physician, who believed his knowledge of chemistry to be adequate and who was asked to pass critical judgment on the work of the laboratory studied the intricacies of the work, and his confidence lessened at every step. Modern clinical chemistry involves, or at least should involve, the frontier of chemistry. An active physician cannot possibly keep abreast of the rapid developments in practical chemistry. I should ask for no better proof of the inadequacy of the determinations of the laboratory than that the attending physician "knows" what is going on. The physician gains little from his exposure to chemistry at best. Much pseudochemistry is encountered by the student after he leaves the chemistry laboratory by overenthusiastic teachers of other subjects. The ideal, of course, is to have in charge of the laboratory a man who has received fundamental training in chemistry in his premedical years and then taken a medical degree, but these men are rarely available and, when available, are frequently undesirable for one reason or another. It is far better to adopt the scheme that has been found to work with unquestionable efficiency. Let the physician ask the laboratory for certain definite determinations. Let the laboratory make the determination as its experience and judgment dictate. Let the interpretations lie with the physician. It is he, not the chemist, who can maintain touch with the meanings of results, the normals and the departures. The chemist has his chore in keeping abreast of the chemical times. The chemist is apt to accept as normal not the data given by his own observations but those published from some distant, perhaps foreign, laboratory. A certain chemist pasted into the end boards of a book he had written a series of normals as he gained the data from reading but checked against his own results interpreted as normal by a medical colleague (applied Biochemistry, ed 2, Philadelphia, W. B. Saunders Company, 1927) yet the list has been subjected to violent criticism, which is justified since the data applied more to the locality in which the determinations were made and less to the results of others in different regions. The physician should see that he is supplied by his laboratory with normals for the region in which he is working and draw conclusions of deviations from these normals as to whether his laboratory reports are within normal limits. Only the physician can determine whether the patient from whom the specimen is taken is normal or otherwise.

And so I would recommend the Monroe Doctrine for the clinical laboratory. The laboratory for the laboratory worker, interpretations for the physician. Far better than placing a medical man in charge of a laboratory is the procedure adopted by many fine institutions: namely, to have one or more chemists of unquestioned standing act as consultants to insure that the methods employed by the laboratory worker are acceptable and modern. Industries pay roundly for such services but they reap rewards.

W. THORW MORSF, PH.D., Lake Bluff, Ill.

### THE CLINICAL APPLICATION OF DUODENAL EXTRACT

*To the Editor* —Since reporting on the clinical application of duodenal extract (Macallum-Laughton) in the treatment of diabetes (Duncan, G. G., Shumway, N. P., Williams, T. L., and Fetter, Ferdinand *Am. J. M. Sc.* 189:403 [March] 1935), my associates and I have received many inquiries regarding the action of this preparation and the likelihood of its permanent value, but most of all its availability for distribution. At least one pharmaceutical firm has quoted our work as corroborating their questionable observations. We of course were not consulted about having our names used for this purpose.

It seems appropriate to recount, through the medium of *THE JOURNAL*, our disappointments, difficulties and the present status of this problem.

Following the apparently excellent results with two or three batches of the extract, made up in small quantities, the effect was lost when treatment with material made in large lots was begun. The former insulin requirement of the two children (G. D. and A. B.) returned. The two patients (T. G. and R. M.) who had been admitted in ketosis were obliged to resume taking large amounts of insulin several weeks after the apparently effective batch of extract was exhausted in spite of the normal dextrose tolerance curves obtained while receiving the extract.

In the interim between 1935 and the present (January 1939) we have not been able to reproduce our original results either in the original or in new patients. It is true that mild beneficial effects were noted occasionally, but they were not maintained nor were they convincing when subjected to critical analysis.

Under the assumption that the original extract made in small batches was effective, the following possible causes for the loss in potency have been considered: (1) changes from small to large quantity production, La Barre's method of isolating the duodenal hormone which was clinically successful in laboratory preparations has also failed to give active material in mass production, (2) changes in the method of extraction and preservation, and (3) obtaining the extract from animals which had not been fed for several days before being slaughtered. This is the most probable. Macallum (*Canad. Chem. & Process Industries* 22:13, 1938) indicates that there is active material, physiologically identical to Young's glycopeptide but possessing greater stability, in the pancreas of starving cattle but that the problem of isolation is complicated by the presence of insulin and a powerful insulin antagonist.

After a survey of the clinical results the following just criticism can be offered. New patients with diabetes were used for our observations and not patients who had had the disease for long periods and whose insulin need was thoroughly known.

There are rare diabetic patients who present an apparently severe form of diabetes when first seen but who, following initial treatment, do well on diet therapy alone for a short period but eventually need large amounts of insulin. That several of these patients should be seen consecutively, as would appear to be the case if this explained our results, is most unlikely, especially when two were children and one was an adolescent youth.

In summary, we have been unable to confirm our early results but believe that the striking effects obtained from an apparently potent duodenal extract were not merely coincidental. Clinical work with the extract has been discontinued pending the outcome of animal experimentation which is being actively pursued by Macallum.

GARFIELD G. DUNCAN, M.D., Philadelphia

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### CEMENT BURNS AND DERMATITIS

*To the Editor*—1 What is the best treatment for skin burns from wet quick setting cement? 2 What is the incidence of recurrence of cutaneous eruptions at the sites of old cement burns? Is the development of blebs containing clear fluid on the once healed areas a criterion of chronic cement poisoning? 3 Is it possible that painful hip and knee joints could be caused by extensive cement burns on the legs three weeks after the wounds have healed?

M D Texas

**ANSWER**—1 Quick setting cements may contain, in addition to calcium oxide, such other cutaneous irritants as potassium sulfide, sodium carbonate, potassium carbonate, alum, calcium chloride and aluminum chloride, but the treatment for burns caused by quick setting cement is the same as for burns caused by ordinary cement, viz the application of mild palliative lotions such as boric acid solution calamine lotion or soothing ointments such as boric acid ointment, zinc oxide ointment or calamine ointment. In addition to this the worker should be removed from further exposure to the cement.

2 Cutaneous eruptions at the sites of old cement burns should not recur unless there is a fresh exposure to cement. However, workers with psoriasis or lichen planus may have an occurrence of these diseases on the site of old cement burns.

The development of blebs containing clear fluid on the once healed areas of cement burns is not a criterion of chronic cement poisoning. There is no such condition as a chronic cement poisoning in the same sense as there is a chronic lead or benzene poisoning. If a dermatitis caused by cement is not properly treated and the exposure to cement continues, a chronic eczema may result. In this condition the skin is thickened and may have cicatricial infiltrations which may become covered with vesicles and pustules. Conjunctivitis and ulcers of the mucous membranes of the nose and mouth and fever may develop at this stage. Such a condition might be termed by the workers chronic cement poisoning.

3 Extensive cement burns on the legs three weeks after the wounds have healed may cause painful hip and knee joints if the cicatrices are deep and pull on the joints, but workers with cement in the open air may suffer from rheumatic pains in the joints resulting from rapid changes in temperature, strain and fatigue, and not due to any damage caused by the cement.

Further information on cement dermatitis may be found in *Queries and Minor Notes*, THE JOURNAL Nov 12, 1938, page 1867.

### PAPULAR URTICARIA AND ALLERGY

*To the Editor*—Will you kindly advise me just what is the underlying cause or what are the factors involved in the well known fact that the urticaria of infants and young children is so frequently papular vesicular or bullous or a combination of such lesions and that the lesions of urticaria in an adult are nearly always wheals? Is it a question of histopathologic differentiation or is it a matter of allergy? Kindly explain in detail if possible.

ALBERT S TENNEY MD East Orange N J

**ANSWER**—First it must be emphasized that the adult type of urticaria (erythema with wheal formation) does occur in children. The type of urticaria which the inquirer describes as occurring in infants and young children no doubt has reference to lichen urticatus or urticaria papulosa. This urticarial manifestation appears to be common in Europe but less common in this country. The lesions begin with small areas of pale pink to deep red blotches or wheals. The wheals last for only a few hours and are frequently present only at night, therefore they are usually missed. The latter are replaced quickly by papules or vesicopapules. The papules last for several days or weeks. They are mainly above the surface of the skin. The itching often leads to excoriation and crusting and subsequent discoloration. Where the skin is thicker, large vesicles or bullae may result. The lesions are discrete and occur particularly on the extensor surfaces of the forearms and legs, on the buttocks and on the lower portion of the back.

The classic description of the tissue changes in the ordinary urticaria are those of capillary dilatation, areolar flush and wheal formation from increased permeability leading to localized edema. In lichen urticatus, Sequeira (*Diseases of the Skin*,

New York, Macmillan Company, 1927) describes the papule as a papillary edema, with infiltration of leukocytes and dilatation of vessels. The corpus mucosum is edematous and under the stratum corneum there is a mass of imperfectly formed corneous cells. The cells of the epidermis are in a spongy condition, resembling that in eczema. While allergy is generally regarded as the most important single factor in the whealing type of urticaria, the status of allergy in papular urticaria is more uncertain and more complex. According to Bray (*Recent Advances in Allergy*, Philadelphia, P Blakiston's Son & Co., 1934) in the majority of such cases dietary and thermal factors are involved. The dietary causes are due primarily to two types of foods. The fats, especially bacon and pork products and fish oil, constitute an important group. The other foods include common allergens such as egg, fish, potato and cocoa. In allergy to the first type of foods, cutaneous reactions are almost never obtained. The factor of heat is an important one, according to Bray, since this rash generally appears only in the warmer months or after warm baths, exercise or other causes for increased temperature of the skin.

It is quite evident, therefore, that lichen urticatus or papular urticaria shows evidence of histopathologic differentiation from the common urticaria. Whether this is due to the nature of the child's skin as differing from that of the adults or whether the explanation lies in the difference of the etiologic factors cannot be definitely ascertained. Nevertheless, in the final analysis, the allergic background is usually present in both of these conditions.

### TENDRA MEAT TENDERIZER

*To the Editor*—A patient has inquired about Tendra. It is used to brush on steak and is supposed to make the muscle tender breaking down the fiber. The patient said it is made from a plant or fruit which comes from South America. Could this be harmful and should patients be advised against using it?

T P BENNETT MD Alliance Ohio

**ANSWER**—There are a number of "meat tenderizers" in addition to one marketed under the name of "Tendra" by Tendra Kitchens, Cincinnati. It appears from information available that Tendra (and some of the other preparations intended for "tenderizing" meat) is made from Carica papaya, or melon trees, of tropical and semitropical districts. The juice of the fruit contains a proteolytic enzyme called papain. Like trypsin, this enzyme is capable of digesting many proteins. From time to time such products have been introduced into therapeutics, although nowadays they have received little use in that connection. It is claimed that by applying an extract containing papain to tough meat it can be rendered more tender, probably by the partial digestion of some of the connective tissue. According to a report of Shiro Tashiro and L H Schmidt in the *American Journal of Physiology* (119 413 [June] 1937) the product is nontoxic when ingested in small amounts by mouth, but workers and others handling the material must exercise precautions to keep their hands washed because otherwise the papain will attack the skin. According to a release of the Federal Trade Commission, the Perfect Manufacturing Company, trading as Tendra Kitchens, Cincinnati, has stipulated that it will cease representing that by using "Tendra" every portion of the meat can be cut with a fork and one can serve the "tenderest meat in town" and that use of "Tendra" shortens the time of cooking by a definite percentage.

### PEPTIC ULCER

*To the Editor*—What is the consensus on the use of vitamins in duodenal ulcer and which vitamins seem most helpful? What are the latest books covering this? What books or other literature are available on their recent efforts in ulcer treatment?

GEORGE TAYLOR, MD Mooresville N C

**ANSWER**—Vitamins have no specific role in the treatment of duodenal ulcer. However, because of the fact that many of the diets for ulcer produce an avitaminosis it might be well to incorporate mixtures of vitamins in the therapy of peptic ulcer. Furthermore, because a patient may have had a previous limited intake of a sufficient number of vitamins it might be included a priori in the diet at the beginning. The latest book on the treatment of ulcer is by G B Eusterman and D C Balfour (*The Stomach and Duodenum*, Philadelphia, W B Saunders Company, 1935). The following are the references for some of the newer works on peptic ulcer.

## HAZARDS FROM GLUE MANUFACTURE

*To the Editor*—I wonder whether there is any industrial hazard in the manufacture of an envelop glue which consists of a tapioca dextrose mixture and acetic acid which is boiled together for about five hours. A patient says that he has headaches daily which are increased by the fumes of this mixture. The reflexes the Wassermann reaction and the heart are normal. Blood examination gives hemoglobin 96 per cent (Sahli), 4 000 000 red cells differential normal 10 000 white cells.

M D Illinois

**ANSWER**—The characteristic point of attack of acetic acid vapors is the conjunctiva. Action may also be exerted on the mucous membranes of the respiratory tract and thereafter on the skin. Unless some of these manifestations have appeared, it is most unlikely that acetic acid is any direct producer of the headaches mentioned in the query. The tapioca powder conceivably might lead to allergic manifestations of which headache might be one. When tapioca is boiled over a long period with acetic acid the chemical reaction that takes place probably leads to hydrolysis with the possible formation of polyhydroxy compounds. Higher aldehydes may be produced. However it is not known that any of these compounds possess toxic properties. The presence of headaches under conditions of prolonged boiling of a product should lead to the suspicion of carbon monoxide poisoning particularly if gas is the fuel.

## STATURE OF AMERICANS

*To the Editor*—Kindly give me the average height for the full grown normal American male and female of this present generation.

M D Ohio

**ANSWER**—This question was referred to Prof. C. A. Hooton of the Department of Anthropology of Harvard who has kindly supplied us with the following tables:

*Statues of Americans (Native Born of Native Parentage)*

		Males			
				Stature	
		Age Range	Number	Cm	Inches
Century of Progress	15 84	1544	174 81	68 82	(geographic totals)
Criminals	15 79	4201	171 90	67 67	
Harvard sons	17 21	480	177 50	69 88	
		Females			
				Stature	
		Age Range	Number	Cm	Inches
Century of Progress	15 79	1840	162 03	63 79	(geographic totals)
Eastern college women	17 19	571	164 53	64 78	

## INTRAVENOUS DEXTROSE AND BLOOD AGGLUTINATION

*To the Editor*—It has been stated that at least four hours must elapse after a patient has had dextrose before the blood is suitable for cross matching with a donor's blood. The presence of 5 or 10 per cent dextrose in the blood stream is said to favor false agglutinations. Is this correct?

M D Idaho

**ANSWER**—The intravenous injection of 5 or 10 per cent dextrose solution does not give rise to false agglutination. While it is true that in vitro high concentrations (above 5 per cent) of dextrose can cause agglutination of red blood cells, in vivo such concentrations are never reached after intravenous injection. It is obvious that if intravenous injections of dextrose were to give rise to false agglutination, attention would have been called to this fact by individuals doing grouping tests yet no report of such a phenomenon has been published in the literature.

## HEPTYL ALDEHYDE AND MOUSE TUMORS

*To the Editor*—I noticed the request from Dr. A. Grebler in *Queries and Minor Notes* January 28 about heptyl aldehyde in mouse tumors. One reference to Dr. Strong's work is found in *Science* (87:144 [Feb. 11] 1938). Dr. Frank Dickens in the 1938 report of the British Empire Cancer Campaign reports work that he has done with Dr. E. W. Miller with feeding heptyl aldehyde to tumor-bearing animals and also with injections of the substance dissolved in sesame oil. He states that neither in transplanted nor in spontaneous mouse tumors have any marked effects on the growth of the tumors been observed although with the transplanted tumors there was slight retardation but it was not possible to state at that time whether or not retardation was significant. He states further that the respiration of tumor tissue (Walker carcinoma and Jensen sarcoma) is more susceptible to heptyl aldehyde than is normal rat tissue (liver kidney testis) but that brain is also rather susceptible. No work on man is reported.

RALPH L. HOFFMAN, M.D., San Diego, Calif.

## Council on Medical Education and Hospitals

## ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Thirty-Fifth Annual Meeting held in Chicago Feb. 13 and 14, 1939

DR. RAY LYMAN WILBUR, Stanford University, Calif.  
in the Chair

## COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 13—MORNING

## Protection of the Public Through Activities of the Council on Medical Education and Hospitals

DR. RAY LYMAN WILBUR, Stanford University, Calif.  
Among the really great possessions of the human race are the code of ethics and other traditions of the medical profession. Rooted in the remote past and of steady growth over the centuries, the established relations of the physician to his patient and to the public have seemed so necessary that they have been taken largely for granted. To grasp their great values one need think only of what would have happened if medicine had been operated on a cut-throat competitive basis regardless of anything else than the money involved. What a sinister picture it would be if the traditions of the profession based on long experience had not been a controlling factor at the beginning of this modern era of the application of science to the relief of human ills. The potentialities of the doctor for good or evil in private life in organized society and in public health are great. It would be impossible to control him by fiat or legislative acts. There is no possible substitute for competence in medical care and competence can come only from education and training. There is a constant increase in the number of people who want good medical care and who know its value. A great movement is stirring for a wider spread of such care throughout the country.

The work of the physician brings him imperative lessons on the damage done to human lives through ignorance. His constant battle with the quack is based on the results to human lives which he knows have come from improper or inadequate treatment fostered by false promises. A lack of scientific appreciation and training makes it difficult for the public to judge many medical questions. So few persons understand biology or know anything about life except that they are living that naturally many can be easily imposed on.

The physician has led in all civilized countries in the efforts to control the activities of those who are inadequately trained for the care of the sick. The public itself has no adequate way in which it can give protection to individuals or to the community without the intervention of the trained scientist and the expert physician.

The policy of licensing physicians was first started in the United States in New York in 1766. Since that time various methods have been employed in an effort to secure for the public an assurance of competence in the practice of medicine. Examining boards of various sorts have been set up. Limitations have been placed around membership in medical societies. Public officials have had to meet certain requirements and have been appointed or elected to carry out the provisions of health laws. Reciprocity between various states has been devised. A national examining board has been set up. These procedures no matter how carefully conducted fail to accomplish many of the results desired. Experience has shown that the only real safeguard which the public has is the requirement that candidates for medical licenses be graduates of established medical schools of good quality. In the past large numbers of medical schools that gave a valueless education have been chartered by the state. When those associated with the American Medical Association decided that steps should be taken to insure a better training of physicians, the Council

on Medical Education was set up to provide those interested, including the state boards of registration, with a reliable and impartial list of medical schools worthy of recognition. No agency except the American Medical Association could be depended on to procure this information in an impartial manner and to present it to the public. The American Medical Association has broad enough shoulders to take the responsibility and can stand up for standards for the protection of the public even at the expense of certain schools. As a result of the activities of the Council on Medical Education which later took on the responsibility of rating certain educational features of the hospitals as well there has been an unparalleled advance in the last thirty years in medical education. The Council is without power over these medical institutions. It can only try to discover the facts, make them public and indicate its judgment as to the merits or demerits of the medical schools or the hospitals for the training of those who are to care for the sick. Its relationship to the hospitals depends on the internships for young physicians and graduate work. It aims to see that no young doctor wastes his time on an internship in which it is impossible to gain sufficient experience and that a physician seeking further training gets full value for his time. A record is maintained of every practitioner from the time he enters medical school until his death.

The activities of the American Medical Association through the Council on Medical Education and Hospitals constitute one of the most potent forces for the protection and care of the health of the American people. Only by learning continuously and keeping up to date can the physician render the best service. The Council therefore has interested itself in the instruction of graduate physicians in medical schools and hospitals and in the development of educational programs in the county, state and national medical societies. It has taken a part in the preparation of opportunities for specialists and in devising plans by which suitable recognition can be given to those who have had satisfactory training. Only trained physicians can judge just what a medical education should be or test the candidate for practice as to competence. The acceptance by the American Medical Association of this great task has resulted in a major service to all mankind.

#### The South as Testing Ground for the Regional Approach to Public Health and Public Welfare

HOWARD W. ODUM, LL.D., Chapel Hill, N.C. There are so many facts available that it seems best to present my comments in a sort of factorial syllabus in which a series of assumptions constitutes the premises for discussion.

1. Public health is a new problem arising from the extraordinary developments in the trends of population, in modern technologic civilization and from the increasingly vital relation between the economy of the people and the health of the people.

2. The population of the Southern states is being and will continue for a long time to be reproduced more rapidly than that of any other region of the nation. Its excess of births over deaths is 10 per thousand, as compared with the national average of 7 per thousand and already it has the most thickly populated rural area in the United States. Of the 108,600,000

native born persons in the country in 1930, 28,700,000 were born in the Southeast, all but 4,600,000 in rural districts. Since the turn of the century the South has sent into the rest of the nation something like 4 million people. It is clear how important to the nation the health and vitality of the southern people are.

3. The South is a region of multiple cultures with subregions representing the lowest measure of health efficiency in the nation and other subregions approximating high standards. Considering the rural and frontier nature of the culture, the situation is often not half so alarming as it appears to the citizen and student versed only in the perfection of urban health and sanitation.

4. The southern regions reflect an extraordinary deficiency in nearly all aspects of public health and medical services and many special problems are found in the South on which special attack must be made for the good of the people, the region and the nation. It is possible to point out a nucleus of four counties in a state of the lower South which had a death rate in 1935 from malaria of from 116 to 130 per hundred thousand of population as compared with only 21.6 for the whole state and 3.6 for the nation. This subregion is surrounded by five counties with a rate of from two to three times the rate of the state and from ten to twenty times the national rate. It is possible also to select a group of counties in the Piedmont subregion with an estimated incidence of 600 cases of pellagra per hundred thousand of population. In another state of the lower South the 1935 health indexes for the whole state indicate that more than three of every hundred people have actually been reported as having malaria, nearly two of every thousand as having pellagra and hookworm and about the same number as having social diseases. It is generally recognized that morbidity is greatly under reported.

One may follow this first series of assumptions with a second series somewhat more specifically applied to the South.

1. A problem to be attacked is that of developing a more balanced economy in which the income and wealth of the people of the South may approximate adequacy for higher standards of living and a richer culture. All the king's horses and all the king's men cannot put together the components which go into an adequate health and medical service for a majority of the people whose income is simply not adequate.

2. On the other hand, the great majority of southern rural folk cannot attain economic effectiveness until they have been adequately conditioned in health and vitality.

3. Basic both to the explanation of the health situation and to the planning of the future is the recognition that a first task, almost prior to public health and medical technique, is provision for adequate diet and general home regimen and sanitation. This applies particularly to pellagra and hookworm on the one hand, and, on the other, to the importance of recent discoveries and contributions in the field of biochemistry and nutrition in the reconstruction of an entire group of people. The minimum dietary requirements for the whole Southeast may be set at 2,450,000,000 gallons of milk, of which there is a production deficit of 1,161,455,000 gallons. Only 62 per cent of all farms reported cows milked and the average number of gallons per animal was only 394, as compared with 618 for the Northeast, 638 for the Far West and 530 for the Middle states. The number of pure bred cattle per farm is less than 1 per cent, as compared with 28 per cent for the nation.

4. A prime problem again almost preceding the problem of the technical tools and administration of public health and medicine, is general health education. It may be no reflection on the people but it is no alteration of the fact that, without opportunity to understand the fundamentals of health, medicine and hygiene, as well as the essential meaning of high standards of living, of work and of food values, the people do not understand needs, opportunities and fundamentals. Many not only do not understand but would oppose standards and procedures. They would continue in many of the folk beliefs and practices which have held them back. There must be an effective bar-

rage of school and adult education to pave the way for the public health program. Indeed this is a part of the testing field for realistic public health planning.

5 Another assumption with reference to the South as a testing field for public health and medical service is that the burdens and handicaps which come from present and prospective deficiencies fall extremely hard on the youth, who, like the youth of the rest of the nation, search for security and reality. In the present and prospective economy and culture of the region not more than half of the youth may hope, under the most optimistic of premises, to find either.

6 The last assumption in the second series has to do with the actual program of public health and medical services. The premise is that in the South there is a supreme need of immediately increasing programs of public health and medicine accompanied by realistic programs of research, education and public welfare planning.

The third and last series of assumptions tends to focus more nearly on the implications of the other series in terms of programs.

1 There does not appear to be any alternative to an increasingly larger contribution to the problem on the part of public health agencies. Inherent in the assumption is the consideration that in proportion as the nation helps enrich its regions it enriches itself and prevents subsequent drain of its resources for relief.

2 In the regular normal machinery of the Southern states and in particular the county unit basis of their public services there is an admirable testing ground for wholesome and effective cooperation between and among the counties, the states and the federal government.

3 Success in all aspects must be predicated on the training and use of a larger number of public health officials and workers as well as the strengthening of the personnel and availability of medical and hospital services. Such training centers as are being developed in the Nashville-Vanderbilt region and in Southeastern Region 2, in the state of North Carolina, represent policies and procedures which should be strengthened.

4 There is an extraordinary need for more study and research in many areas. There are almost no reliable data to give an adequate basis for conclusions in relation to diet and climate in the South or with reference to the environmental influences in farm tenant and other groups.

5 In view of these facts and the fundamental situation with reference to the growing population and the inadequacy of resources, a fifth assumption naturally focuses on sound programs relating to birth control. The North Carolina birth control clinical services are representative of what might be done, clinics already being in operation in between sixty and seventy counties in the state.

6 There is great need for an increasing number of experimental services in this and in many other fields distributed throughout the various subregions and comprehending private and public efforts. The University of North Carolina Division of Public Health expects to have, through a grant from a private agency devoted to the study and reduction of social diseases, a full time professor of syphilology.

These assumptions indicate both the nature and the promise of the South as a testing ground for the regional approach to public health work. From the premise that the South has a superabundance of natural wealth and human wealth but that there is an extraordinary degree of waste in both, the conclusion is justified that for science skill and the professions devoted to the development, conservation and utilization of all resources in harmony with a practical adaptation to the normal process of democratic government and civic cooperation it will constitute the perfect testing grounds for next steps.

#### DISCUSSION

DR L. J. KOSMINSKY, Texarkana, Ark. In Arkansas under the state health officer Dr W. B. Gravson, there is a good strong program with health units. The counties do not

all have them, but through the American Legion and the Forty and Eight, cooperating with the state department of public health, serums of all types, diphtheria toxoid and vaccines are being issued and typhoid immunization and treatment for syphilis are being given free irrespective of whether the recipient is indigent, in an effort to eradicate the diseases concerned. In my county in the last year several children were given rabies serum, which was furnished by the state health department. They were also given antitetanus serum. Physicians should teach rural families how to have good health and to provide during the productive months for foodstuffs for the winter. Many families who have milk and make butter and sell it in town do not give their children any milk or butter.

DR R. N. WHITFIELD, Jackson, Miss. I will be glad if you will not think that the South is in such a bad situation as you might from the address you have just heard. A man from the University of North Carolina got his Ph.D. degree by coming to my office and getting one year's statistics on births and going back in two or three weeks with his thesis. He had proved that the birth rate is higher on some soils than it is on others. I did not find out what soil it is in Mississippi that produces a higher birth rate than any other, but I might guess that it is sandy soil down where they have or have had the hookworm disease. There are some good things in the South. The work of the state board of health is free from politics in Mississippi, and I understand that this is not true in a great many states in the North and in the East. Visitors have come from all over the United States, Europe, Asia and South America to learn our methods. There are only two states in the Union with a Negro population of less than 10 per cent that have a lower death rate than the white people of Mississippi. It seems that the South is a testing ground right now. I guess that there are 100 WPA projects in Mississippi alone—sewing projects and every other kind of project. The country down there is a little poor financially, but it is doing fine.

DR ANTON J. CARLSON, Chicago. I have seen mass deficiencies in nutrition in many parts of the world. I am disturbed by the speaker's all-inclusiveness, as if the physician under the program of public health, is to be the savior of mankind. I think that we shall have to differentiate a little. The doctor is not a farmer. Part of the difficulty with nutrition in the South is of course the lack of diversified farming and the lack of distribution of foodstuffs from other parts of the country. It would be unfortunate to hook up all these things all the while in the South, with what a program of public health is ordinarily understood to be. The program is entirely too broad for the doctor. Soil conservation, diversified farming and education in the fundamentals of biology and nutrition must be carried on through other agencies which already exist. The essential program of public health should not be obscured by this all-inclusiveness. I listened to a Negro sharecropper from the South and he prided himself on the fact that there is no shortage in the crop of children. One of the big educational needs is what the speaker mentioned, namely birth control. There should be no pride in mere numbers, regardless of the proportion of incompetents and unfortunates.

DR HOWARD W. ODUM, Chapel Hill, N. C. Because the problem is so important so big and so conditioned by economic social and historical factors, the physician cannot manage it alone. It must be a problem of cooperation. Few things are more futile than a superimposed artificial program set up by a group of single-track specialists. Mississippi is my favorite state. I was three years at the university. The man mentioned took five years to get his doctor's degree and he is teaching at the University of Florida. Southerners are the best people in the world, but I am looking at facts as they are, and they must be faced. I want to stress the nonacademic realistic practical value of recognizing the regional folk because in diversity there is strength in America.

## Book Notices

**Essentials of Pathology** By Lawrence W Smith MD Professor of  
Pathology Temple University School of Medicine Philadelphia and  
Edwin S Gault MD Associate Professor of Pathology Temple Univer-  
sity School of Medicine Philadelphia With a foreword by James Ewing  
MD Memorial Hospital New York City Cloth Price \$9 Pp 886  
with 679 illustrations New York & London D Appleton Century Com-  
pany Incorporated 1938

This presents an interesting excursion in pedagogic technic,  
involving as it does the use of the case history method for  
teaching which, in the words of Ewing's introduction, is  
employed "to take the teaching of pathology out of the realm  
of abstract philosophy and make it an effective force in the  
professional equipment of the medical student" The textbook  
which Smith and Gault have so constructed will provide an  
excellent instrument to test the advantages of teaching from this  
point of view That the case history method will have advan-  
tages must be obvious There are inherent dramatic features  
which arouse interest there is close integration with the clinic,  
and with this an early familiarity with clinical terms is estab-  
lished, there is recognition that in reality "pathology" and  
'disease' are not to be compressed into stereotyped categories,  
finally there lurks the possibility that pathology will be envi-  
sioned as a dynamic process rather than as a wholly anatomic  
and static one All these possibilities, though not expressed in  
the preface, were no doubt in the minds of the authors The  
case history method may however, bring with it disadvantages  
which must be considered from the standpoint of the instructor  
in pathology Let us visualize a student out on the street on  
a dark night suddenly confronted with the dim outlines of a  
vast building Myriads of dark windows range toward the sky  
No street signs are visible, no door is evident, the student  
pries open a window, climbs in turns on a light and examines  
the contents of the room From one room he enters the next  
and repeats the process ad infinitum until he has examined every  
room As he finds much of interest in many of the rooms, the  
tour becomes fascinating Most of us, however, prefer to  
approach a building in daylight, knowing the street and number,  
observing its relation to adjacent structures If the building is  
of importance, we might wish to know something of the architect  
and builder and possibly examine the floor plans so that we  
may have some sense of direction once we have entered the  
structure

In pathology as projected for the student in the Smith and  
Gault manner the mental approach must involve something of  
the nature that has been implied because there is no beginning,  
and no growth only the finished and completed frame work is  
to have validity the rest is not of the 'essentials' and there-  
fore can be sacrificed to the exigencies of the world's fast pace  
One may deny the expediency while granting the exigency We  
frequently decry the narrowness of the modern specialist mourn  
the scholar of the passing generation We realize the inherent  
dangers of our cubicle system of instruction and now we are

to teach this basic medical science as though it were another specialty. If the student is to get a broad perspective anywhere in medicine he must get it in pathology, for today there certainly is little perspective even in medicine as taught in modern medical schools. There is another possible difficulty. General pathology as now fitted into the medical curriculum is usually taught in the second year. In the case history method much clinical detail is involved the significance of which cannot possibly be grasped by a sophomore student who has never had contact with a patient, who has never taken a history, who in many instances is still in the early stages of his knowledge of physiology. It is doubtful whether a sophomore student is prepared to evaluate, even if he has time to absorb, all the clinical features spread out before him. That he is in danger of seeing the trees and not the forest comes to mind when one reads the chapters on inflammation, after all the keystone of any course in pathology. Nowhere are the obvious questions of why and how ever approached. But if the student is not to be interested in the basic reactions of inflammation if he is to slur over the chemical and physical alterations that are reflected in his histopathologic slide, of what use is it to him merely to pile up the unlimited variety of the inflammatory pictures which the microscope can reveal?

This textbook is an experiment in pedagogy, the advantages that have been suggested for this method may possibly far outweigh the objections that are listed—and they have been listed not in criticism of the work, which is excellent, but possibly of the method. The authors and the publishers have provided a first class teaching apparatus, whether the method will be superior to the old one is a question that can be determined only after proper trial. Certainly no pathologist would suggest that we have perfected a teaching technic that could remotely be considered approaching an ideal. The text itself offers a well balanced presentation of both general pathology and the special pathology of the various organ systems. About one fourth of the text is devoted to the various degenerations and inflammations, another fourth to tumors, and the remaining half to special pathology. The descriptive text leaves nothing to be desired, it is clear and concise and special effort has been made to present the orthodox point of view, controversial subjects have been avoided. While this at times results in a somewhat colorless impression, it has decided advantages in a book which aims at brevity in presentation. Reviewers can always find fault in the treatment of selected topics, but the teacher of pathology will probably find little cause for dissent. The paper used is not highly enameled, which makes for restful reading though it may possibly at times impair the quality of some of the illustrations. These are abundant and all are provided with concise and proper legends to integrate them with the text. They are by no means limited to the microscopic field but include also the gross specimen and in some instances the patient. In a series of color plates, drawings of microscopic fields have been reproduced, these include cells from inflammatory exudate, blood cells and arterial changes.

**Chemie und Technik der Gegenwart** Herausgegeben von Dr. H. Carl, Dozent an der Universität Leipzig. Band VI. Vitamine und Hormone und ihre technische Darstellung. Teil I. Ergebnisse der Vitamin- und Hormonforschung. Von Dr. Hellmut Brederick, Dozent an der Universität Leipzig, und Dr. Robert Wittig. Second edition. Boards. Price 7 maris. Pp. 138. Leipzig: S. Hirzel, 1938.

This is a technical review of recent chemical research on the vitamins and hormones and is the first volume of a series. The remaining three volumes will be concerned with the preparation of vitamin and hormone products. The sex hormones will be the subject of a separate volume, the fourth in the series.

It is interesting to note that the authors refer to vitamin A as "xanthoptol." This name is unfortunate because it refers to but one symptom of A deficiency in animals. Moreover the name is chemically uninformative. The discussion of the chemistry of vitamin A is brief and clear. There is included a description of the synthesis of vitamin A according to Kuhn. Vitamin B<sub>1</sub>, for which the authors have not used the preferred American term thiamin chloride, is also discussed briefly but in sufficient detail. The methods of preparation of riboflavin are described. Mention is made of some of the other members of the vitamin B complex, but no reference is made to nicotinic acid. Discussion of the organic chemistry of vitamin C is fairly

complete. There is a brief description of vitamins D and E, with many chemical formulas. Brief mention is also made of vitamins H, J, K and P. There is a section also on the relation between vitamins and ferments which is limited to a discussion of the yellow ferment co-carboxylase and ascorbic acid. The organic chemistry of the hormones accounts for the subject matter of a little more than half of the book. A goodly portion of this material is concerned with sex hormones. There is a discussion of insulin, including the recent work on its composition. Epinephrine and the cortical hormone are discussed in detail. The chemistry of thyroxine is discussed briefly but adequately. Brief mention is made of the chemistry of the parathyroid, the hypophysis and other ductless glands, and to histamine, acetylcholine and related compounds. There is practically no mention of the hormones of the intestinal tract. This is surprising in view of the brief discussion of plant hormones with which the book concludes.

**Emotion and the Educative Process. A Report of the Committee on the Relation of Emotion to the Educative Process.** By Daniel Alfred Prescott, Ed. D., Chairman, Professor of Education, Rutgers University, New Brunswick, N. J. Cloth. Price \$1.50. Pp. 323. Washington, D. C.: American Council on Education, 1938.

This work is a report to the American Council on Education by the Committee on the Relation of Emotion to the Educative Process. It is a thoroughgoing report which analyzes the mechanisms of emotion and their application to teaching. The literature has been combed, and the material evaluated. In the introduction the author of the volume gives credit to other members of his committee for supplying most of the material, nevertheless he has compiled and written it, and he assumes the chief responsibility for the work. There are twelve chapters. The first four deal with psychologic descriptions of emotion and affective phenomena with the physiologic basis of emotion and behavior, one is devoted to a discussion of how greatly emotion may be modified by training. The book then passes on through the next several chapters to discuss what is meant by maturity and emotional reaction and how the basic personality needs are modified by various conditions so that maturity might not be arrived at, and there are discussions of the effects of contemporary social institutions on emotion. The remainder of the book treats of the influence of emotion on learning and evaluates the importance of education in controlling and modifying emotion. There are a number of individual discussions in these chapters which are of great value, not the least of which are incorporated in the eleventh chapter, dealing with personnel problems in education. In this chapter the question is brought up whether the educational profession satisfies the personality needs of teachers and points out how important maladjusted teachers are in disorganizing a school system. There are also discussions of the pupil-teacher relationship and how to deal with emotional problems in the school. The last chapter is a summary of the whole project. There is an excellent bibliography covering 180 references dealing with emotion and teaching. The whole work is a serious, comprehensive and worthwhile monograph. There are no case histories. The material is not particularly predicated for the medical man, but the psychiatrist, particularly the one who deals with children should find the book of considerable interest in outlining the present status of emotion in terms of the psychology of learning and of education.

**Guiding Human Misfits. A Practical Application of Individual Psychology.** By Alexandra Adler, M.D., Research Fellow in Neurology, Harvard University. Cloth. Price \$1.75. Pp. 38. New York: Macmillan Company, 1938.

This little book is written by Alfred Adler's daughter. In a brief fashion Dr. Alexandra Adler attempts to cover the field of child guidance, neurosis in childhood, problems of adolescence, significance of dreams and earliest recollections, and some practical aspects of child guidance and psychotherapy, but since the book is not very extensive it is obvious that this must be carried out in a superficial fashion. Alexandra Adler's underlying psychiatric philosophy is that of her father with some modification, namely, that people who are in an inferior position in life as the result of organic defect, rank in the family or social inferiority compensate for this and either retreat from reality through neurosis or into bad behavior. She cites numerous examples, not in the form of complete case histories but rather

an interesting but superficial discussion of many cases. Each chapter describes one or two illustrative cases but, of course, the whole field of behavior disturbance or neurosis is not covered. The author's experience with children seems to be limited by the fact that her philosophy of treatment is confined chiefly to the so-called individual psychology school of mental treatment. While there is no frank criticism of other schools of psychiatric thought, her vision is so limited that modern psychiatrists will not find that this book gives either a new and useful point of view or even a complete understanding of the mechanisms of behavior problems in children or of their treatment.

**Alkoholemi** Studier over Rusen I Af Max Schmidt [Alcoholemia Studies on Intoxication] Denne Afhandling er af det lægekandidatlige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad. København. Læger. Pp. 328 with 20 illustrations. Copenhagen. NIT Nordisk Forlag. Arnold Busch. 1937.

This monograph is of great interest to physiologists, pharmacologists and physicians concerned with the medicolegal aspect of alcoholism. The author presents his own extensive studies of alcohol concentration in arterial, venous and capillary blood in cerebrospinal fluid and in urine during the first two hours after taking various quantities of alcohol, on the fasting stomach and after food and gives good critical summaries and evaluations of the relevant literature. The author's material includes also 400 medicolegal cases in which the amount of the alcohol ingested was unknown or in dispute. In the few cases tested the concentration of alcohol in the cerebrospinal fluid tended to exceed that in the arterial blood. The author studied also alcohol concentration in the blood of normal people not ingesting alcohol and accepts as probable the view that a trace of alcohol (production and ultimate oxidation) is part of normal metabolism and not dependent on fermentation of carbohydrates in the alimentary tract.

**Medicine in the Outpatient Department. An Introductory Handbook.** By Winthrop Wetherbee Jr. M.D. Junior Visiting Physician Boston City Hospital Boston. With a foreword by George R. Minot M.D. S.D. F.R.C.I. Professor of Medicine Harvard University Boston. Fabrikhold. Price \$1. Pp. 111. New York & London. Paul B. Hoeber Inc. 1938.

This excellent, simple book may be read with a great deal of pleasure and profit in about an hour. The author has collected many common experiences and routine procedures of medical practice which will help the student in his clinical study of the patient. Especially commendable is the collection of clinical maxims. Every student will appreciate these as his medical experience increases and every medical practitioner likewise will enjoy rereading them. This book supplies the long needed practical suggestions so definitely lacking in the textbooks of physical diagnosis. It is a notable contribution.

**Milk and Nutrition. New Experiments Reported to the Milk Nutrition Committee. Part III. The Effect of Commercial Pasteurization on the Nutritive Value of Milk as Determined by Experiments on Calves.** From the National Institute for Research in Dairying (University of Reading) and the Rowett Research Institute, Bucksburn, Aberdeen. Paper. Price 6s. Pp. 27. Sharnfield, Reading, England. National Institute for Research in Dairying. 1938.

This report of the Milk Nutrition Committee is concerned with the Aberdeen studies of the relative effects of pasteurized and raw milk in the feeding of calves. An earlier report of this comprehensive investigation on the nutritive value of milk was concerned with the relative effects of pasteurized or raw milk on the growth and health of school children. As in the feeding experiments with children, so in the present better controlled experiments with calves there was little difference observed in growth on pasteurized as compared with raw milk. Because of the safety of pasteurized milk, the conclusion may be drawn that the pasteurization of milk is a desirable procedure in the preparation of milk for human consumption.

**Text Book of Histology for Medical Students.** By Evelyn E. Hewer. D.Sc. Cloth. Price \$4.50. Pp. 365 with 340 illustrations. St. Louis. C. V. Mosby Company. 1938.

This is a concise, elementary textbook of histology written primarily for medical students. The text is generously illustrated with mediocre free hand drawings and photomicrographs. This publication lacks the fundamental detail necessary for understanding histology. It is far below the standard of textbooks of histology published in this country.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Evidence Admissibility of Statements Made by Examinee to Examining Physician.**—A physician, said the Supreme Court of Missouri, Division No. 2, who has been in attendance on a patient for the purpose of treatment, may testify as to present symptoms or complaints of his patient as told to him by his patient and also as to his observations from his examination of the patient. He may not testify, however, as to statements made by his patient with respect to his past physical condition or with respect to the circumstances surrounding the injury or the manner in which the injury was received. If, as was stated in the case of *Coghull v. Quincey O & K C R Co* (Mo.), 206 S. W. 912, the physician has examined a person for the purpose of preparing himself as a witness in a case then pending or which is expected to arise, different considerations must be recognized, for then there exists a temptation to falsify or at least magnify, the true condition.—*Evans v. Missouri Pac. R. Co* (Mo.), 116 S. W. (2d) 8.

**Workmen's Compensation Acts. Insurer May Recover Damages from Physician Who Negligently Treats Employee.**—Baker, in the course of his employment, injured his left leg and was treated by the company physician. A diagnosis of dislocation of the hip was made and treatment rendered accordingly. The patient, however, continued to complain of pain. About eight months after the injury, the physician discovered that "the man had really suffered a fracture of the bone at the neck of the femur, but thought he could see evidence of callous and 'thought probably he would get a fairly serviceable fibrous union'." No change in treatment was prescribed. Pain in the leg persisted, there was some looseness at the left hip joint and the left leg was shorter than the right. Later the industrial commission sent the workman to another physician, who performed a reconstruction operation during which an ununited fracture at the neck of the femur was found with almost complete absorption at the neck and a small devitalized shell representing the head of the femur. While the workman thereafter gradually improved, he was permanently partially disabled.

Compensation was paid Baker and all his medical and hospital bills were paid. Subsequently he brought suit for malpractice against the company physician. The industrial commission, being the administrator of the state insurance fund from which compensation had been paid to Baker, intervened, alleging that Baker's cause of action had by statute been assigned to it and that it was subrogated to his rights. The trial court denied the right of the workman to recover from the physician but rendered judgment in favor of the industrial commission in an amount in excess of what it had paid. Pending an appeal to the Supreme Court of Utah the physician died, and his administrator continued the action.

The workmen's compensation act of Utah contains this provision:

When any injury for which compensation is payable under this title shall have been caused by the wrongful act of a third person the injured employee or in case of death his dependents may at their option claim compensation under this title or have their action for damages against such third person and if compensation is claimed and awarded the employer or insurance carrier having paid the compensation shall be subrogated to the rights of such employee or his dependents to recover against such third person provided if such recovery shall be in excess of the amount of the compensation awarded and paid then such excess less the reasonable expenses of the action, shall be paid to the employee or his dependents.

Under this provision said the court, the industrial commission had the right to sue the company physician, for when Baker accepted compensation from the commission after he was aware of the negligence of the physician any right of action he had against the physician passed to the industrial commission. The trial court was warranted in finding, the Supreme Court thought, that the company physician in his

diagnosis and treatment did not exercise such reasonable care and diligence as is ordinarily exercised by physicians in the locality in which he practiced. Nor did the trial court err in admitting the testimony of physician witnesses as to what diagnosis in their opinion would have been made by the average practitioner in the community, having the roentgenograms before him and having had them taken under his orders or direction. The witnesses did not thereby pass on the question of negligence and thus invade the province of the jury. It is permissible, the court said, to allow a medical witness to testify as to what an ordinary physician in the locality holding himself out as able to interpret roentgenograms, could or should have seen in them.

Neither did the trial court err in rendering judgment for the industrial commission in a sum greater than the commission had paid out, the excess being payable to the injured workman. The workmen's compensation act clearly provides that a judgment against the third person tort-feasor may be recovered in excess of compensation awarded and paid but that excess must be paid to the workman.

For the reasons stated, the judgment in favor of the industrial commission against the physician was affirmed.—*Baker v. Vcoff (Utah)*, 79 P (2d) 77

Association for the Study of Internal Secretions St Louis May 13-14 Dr E Kost Shelton 921 Westwood Blvd Los Angeles Secretary

Association of American Physicians Atlantic City N J May 2-3 Dr Hugh J Morgan Vanderbilt University Hospital Nashville Tenn Secretary

Association of Military Surgeons of the United States Washington, D C May 8-10 Dr H L Gilchrist Army Medical Museum Washington D C Secretary

California Medical Association Del Monte May 1-4 Dr George H Kress 450 Sutter St San Francisco Secretary

District of Columbia, Medical Society of the Washington May 3-4 Mr Theodore Wiprud 1718 M St N W Washington Executive Secretary

Federation of American Societies for Experimental Biology Toronto Canada Apr 26-29 Dr D R Hooker 19 West Chase St. Baltimore Secretary

Florida Medical Association Daytona Beach May 1-3 Dr Shaler Richardson 111 W Adams St Jacksonville Secretary

Georgia Medical Association of Atlanta Apr 25-28 Dr Edgar D Shanks 478 Peachtree St N E Atlanta Secretary

Illinois State Medical Society Rockford May 2-4 Dr H M Camp 224 S Main St Monmouth Secretary

Iowa State Medical Society Des Moines Apr 25-27 Dr Robert L Parker 3510 Sixth Ave Des Moines Secretary

Kansas Medical Society Topeka May 1-4 Mr C G Munns 112 W 6th St Topeka Executive Secretary

Louisiana State Medical Society Alexandria Apr 24-26 Dr P T Talbot 1430 Tulane Ave New Orleans Secretary

Maryland Medical and Chirurgical Faculty of Baltimore Apr 23-26 Dr Walter Dent Wise 1211 Cathedral St Baltimore Secretary

Mississippi State Medical Association Gulfport May 9-11 Dr T M Dye McWilliams Bldg Clarksdale Secretary

Missouri State Medical Association Excelsior Springs Apr 10-12 Dr E J Goodwin 634 North Grand Blvd St Louis Secretary

Nebraska State Medical Association Grand Island May 2-4 Dr R B Adams 414 Federal Securities Bldg Lincoln Secretary

New Mexico Medical Society Gallup May 11-13 Dr L B Cohenour 219 W Central Ave Albuquerque Secretary

New York Medical Society of the State of Syracuse April 24-27 Dr Peter Irving 2 East 103d St New York Secretary

North Carolina Medical Society of the State of Cruise to Bermuda, May 9-14 Dr T W M Long Roanoke Rapids Secretary

North Dakota State Medical Association Fargo May 8-10 Dr Albert W Skelsey 20 1/2 Broadway Fargo Secretary

Ohio State Medical Association Toledo May 3-4 Mr C S Nelson, 79 E State St Columbus Executive Secretary

Oklahoma State Medical Association, Oklahoma City May 1-3 Dr L S Willour Third and Seminole McAlester Secretary

Pacific Coast Surgical Association San Francisco Oakland Del Monte March 28-31 Dr H Glenn Bell University of California Hospital San Francisco Secretary

Society for the Study of Asthma and Allied Conditions Atlantic City, N J Apr 29 Dr W C Spain 116 E 53d St New York Secretary

South Dakota State Medical Association Aberdeen Apr 24-26 Dr Clarence E Sherwood Madison Secretary

Tennessee State Medical Association Jackson Apr 11-13 Dr H H Shoulders 706 Church St Nashville Secretary

Texas State Medical Association of San Antonio May 8-11 Dr Holman Taylor, 1404 West El Paso St Fort Worth Secretary

### CENTRAL SOCIETY FOR CLINICAL RESEARCH

*Eleventh Annual Meeting Held in Chicago Nov. 4 and 5 1938*

The President, DR WILLIAM H BUNN, Youngstown, Ohio,  
in the Chair

(Continued from page 1017)

#### Serum Sickness Effective Treatment and Probable Prophylaxis by Means of Histaminase

DRS LEE FOSHAY, Cincinnati, and O L HACEBUSCH, St Louis. The important work presented to the society last year by Dr Grace Roth on histaminase indicated to us that this enzyme should be effective in controlling the symptoms and other manifestations of serum sickness. This expectation has been tested and verified by the treatment of twenty patients, selected at random, most of them with the severer forms of this disorder. Sixteen were treated on either the first or the second day of illness, and thirteen obtained relief in from eighteen to thirty-six hours or less. In most cases the clinical responses were actually dramatic. A beginning attempt at prophylaxis has been made, with extremely hopeful outlook. The treatment seems to be rational, highly effective, safe and devoid of untoward by-effects or after-effects.

#### DISCUSSION

DR LOUIS E PRICKMAN, Rochester, Minn. I have not used this preparation in the treatment of serum sickness but I have had considerable experience with it in the treatment of vasomotor rhinitis. The study of vasomotor rhinitis has one outstanding advantage. It permits one to observe objectively changes which may occur from time to time. Of twenty-six carefully selected and studied cases of vasomotor rhinitis definite relief from this preparation was obtained in only nine (34 per cent). In four cases the results were questionable, in the remaining thirteen cases (50 per cent) no relief whatever occurred. On the other hand striking beneficial results were obtained in certain cases in which my associates and I had tried many different means of relieving the distress without any benefit whatever. Although

certain of my patients have obtained satisfactory results from the use of this preparation, the results in the whole group of cases of vasomotor rhinitis are certainly in contrast to those reported by Drs Foshay and Roth. This discrepancy may be attributable to many factors only a few of which I shall mention. Vasomotor rhinitis is a chronic disease, in contrast to serum sickness, in which the symptoms are acute and not of long duration. One important point is the apparent variability of the material itself. This must certainly be reflected in the results reported, as it has been demonstrated both clinically and experimentally. Although the material is said to be nontoxic and although Dr Foshay has noticed no toxic effects in any of his cases I have some evidence that there may be a limit of tolerance to the oral administration of the preparation. One of my patients who obtained great relief of vasomotor rhinitis (due to food sensitivity) from this material noted that when the dose was increased beyond a certain point she had distressing abdominal cramps. She is still using the material but must be careful not to exceed a certain dose. Finally, when the material is found to be effective in vasomotor rhinitis its use must be continued; it therefore does not appear to be a desensitizing agent. It does not seem to affect the fundamental allergic nature of the patient but seems to have an effect on the allergic reaction.

DR GRACE ROTH, Rochester, Minn. I continue to obtain good results in patients who have a hypersensitivity to cold. I have added to that group some patients who are hypersensitive to insulin with whom I am doing equally well. I want to call attention to the batches of the preparation sent out. The last patient with local hypersensitivity to insulin was put on one batch and the local lesions disappeared. Then for two days I gave him tablets of another batch, and the local lesions returned. When I returned him to the tablets of the first batch the lesions disappeared, and he has had no further trouble.

DR HEINRICH NECHLES, Chicago. I should like to ask the authors whether my impression was correct that histaminase given intramuscularly had a longer latent period than that given by mouth. It is known from the work of Best and his co-workers that the body contains much histaminase and the dose of a few units of histaminase administered by the authors seems to be therefore insignificant in comparison to what the body actually contains. Taking into consideration what Drs Roth and Foshay said, I wonder whether the therapeutic effects reported may not be nonspecific rather than due to histaminase.

DR PHILIP W. BROWN, Rochester, Minn. I should like to ask the authors, for scientific as well as personal reasons, whether they have had opportunity to use this treatment for giant urticaria, or whether the rest of the discussers have had opportunity to use it.

DR LEE FOSHAY, Cincinnati. I realize that we know little about the composition of this compound. It is undoubtedly a mixed substance, and how much of it is actually histaminase has never been shown. I think one should be careful about the selection of proper patients for its use. I am sure it is going to be widely used and abused for a great variety of demonstrated and suspected so-called allergies. I have heard from two discussers today and from other persons that different batches of the material have varied in potency. As I have said, all of mine came from one batch. The effect of intramuscular injection appears sooner than that of oral administration. The shortest period observed was twenty minutes and three patients obtained marked relief after six, eight and ten hours respectively. We did not usually get such prompt results from patients using the enteric coated tablets by mouth. I believe that peptone injected intramuscularly produces considerable reaction. No untoward reactions were noted in our patients receiving injections. I have not used the substance in giant urticaria. I thought it wise to restrict its use to the one condition for which I had adequate controls, and one which is easily recognized clinically and is readily measurable with regard to severity and duration. I know of its use for one patient with angioneurotic edema. This patient was comfortable with great reduction in the edema during the time of administration of the tablets or the injections. However, the edema returned to its previous state from nine to fourteen hours after the cessation of injections or oral administration.

### The Cholinergic Nervous System and Its Relation to the Thyroid Gland

DRS A. R. MACLEAN, B. T. HORTON and A. C. DAVIS, Rochester, Minn. It has been previously understood that sympathetic stimulation occurs in hyperthyroid states. It is our opinion that any sympathetic (adrenergic) stimulation that may occur in the hyperthyroid state is overshadowed by a stimulation of the parasympathetic (cholinergic) nervous system. The stimulation of the cholinergic nervous system of normal persons with acetyl-beta-methylcholine chloride (mechoyl) produces signs and symptoms that simulate those of the hyperthyroid state. Persons who have hyperthyroidism have markedly increased sensitivity to this drug. Myxedematous patients appear to have a paralysis of this nervous system and an increased tolerance to mechoyl.

#### DISCUSSION

DR LOUIS N. KATZ, Chicago. I wonder whether the authors are not carrying their interpretations too far. I am sure they know that mechoyl, like other cholinergic substances, not only stimulates the parasympathetic myoneural junctions but acts on all synapses in the peripheral ganglions in the autonomic nervous system. Because of this, the cholinergic substances in the animal and in man have not only a parasympathetic but also a sympathetic stimulating action. In addition, it has been shown that cholinergic substances bring about an outpouring of epinephrine. A cholinergic substance like mechoyl cannot be used to distinguish between parasympathetic and sympathetic stimulation. I should like to ask the authors whether they used atropine to prevent the manifestations from mechoyl and whether they have used prostigmine, a derivative of physostigmine, in patients with thyroid disease. Prostigmine acts to enhance cholinergic activity and gives less dramatic but more protracted effects.

DR GRACE ROTH, Rochester, Minn. I think Dr Katz's criticism is well taken. I think the results should be taken only as a theoretical interpretation until more physiologic work is done, and care should be used in calling the stimulation either parasympathetic or sympathetic. However, in this study the basal metabolic rate was definitely increased by the subcutaneous injection of mechoyl.

DR A. C. DAVIS, Rochester, Minn. We realize that the interpretation which we have placed on our results is open to criticism from a number of angles. Of course it is rather difficult to say just why these patients overreact. Perhaps the reaction from hyperthyroidism is the same as overreaction of any kind—from nervous shock and many other nonspecific agents. However, it seems to us that the individual reaction to hyperthyroidism is similar to the reaction to an injection of mechoyl. With regard to Dr Katz's question in reference to prostigmine and physostigmine, we have not used them in this connection.

### Clinical Desensitization to Wheat with a Derivative of Acetylcholine

DR ENMET F. PEARSON, Springfield, Ill. Asthma, vasomotor rhinitis, eczema, urticaria and angioneurotic edema were reproduced in seven patients who complained of one or more of these symptoms by addition of wheat products to the diet. The symptoms subsided promptly on withdrawal of wheat. The same symptoms peculiar to the individual subject were reproduced at will by injection of approximately 10 mg. of acetyl-beta-methylcholine chloride (mechoyl). While wheat was eliminated from the diet the patients were given daily injections of mechoyl in increasing doses from 0.5 mg., as tolerated by the patient. After from thirty to sixty days wheat was again added to the diet, and the original symptoms did not recur. In four of the patients previous attempts to desensitize with wheat extract had been unsuccessful. Symptoms have now been controlled for at least six months. It is postulated that repeated cholinergic stimulation alters the status of the bodily reactions so that a tolerance is gained for other stimuli.

### Fatty Acids as Cholesterol Solvents in Bile

DRS CLARENCE F. G. BROWN and RALPH E. DOLKART and K. K. JONES, PH.D., Chicago. Gallstones rarely form spontaneously in dogs, sheep, cats and rabbits. In contradistinction, in human beings, oxen and hogs biliary calculi occur frequently. Experiments carried on by means of shaking human gallstones in solutions of animal bile, bile salts and other mediums and by

direct insertion of human gallstones into the gallbladders of dogs demonstrated that greater dissolution occurred in the bile of dogs and sheep and less in the bile of human beings, oxen and hogs. Fractionation of the bile showed that the capacity of the bile as a cholesterol solvent could be isolated in the saponifiable or fatty acid fraction. This fraction was found to be high in the bile of the dog and sheep and significantly reduced in amount in the bile of animals which form gallstones. Repetition of the shaking experiments with tablets made of pure cholesterol confirmed the observation of greater activity of fatty acids as cholesterol solvents as compared with solutions of bile salts. It was found in addition that for each mixture of a specific bile salt with varying concentrations of a fatty acid there was an optimal concentration which if exceeded or not reached resulted in an inhibition of the rate of dissolution obtained with the fatty acid alone. Our data indicate that the cholesterol is held in solution in the bile by the fatty acids rather than the bile salts.

#### Calcium Balance in Thyroid Disease

DRS. ITAIO D. PUPPEL, KARL P. KLASSEN and GEORGE M. CURTIS, Columbus, Ohio. Three normal persons maintained on a constant low intake of calcium remained in negative calcium balance. Four patients with exophthalmic goiter similarly maintained revealed an increased mobilization of calcium and a tremendous increase in excretion of this element through both the urinary and the gastrointestinal tract. Likewise, two patients with toxic nodular goiter showed an increase in excretion of calcium, but only slightly over normal. On the other hand two patients with nontoxic nodular goiter remained in physiologic calcium balance. Increased feeding of calcium to a normal person on a low intake of calcium produced an immediate positive calcium balance. Similar increased feeding of calcium to a patient with hyperthyroidism resulted in a retention of calcium which was six times normal and a consequent positive calcium balance. One patient with exophthalmic goiter had shown an increase in the negativity of the calcium balance prior to subtotal thyroidectomy. Examination two years postoperatively revealed an absence of all characteristic symptoms and a basal metabolic rate of  $-9$  per cent. Studies of calcium balance showed that the excretion of calcium was also normal and that the calcium balance had returned to within normal limits.

#### DISCUSSION

DR. RUSSELL M. WILDER, Rochester, Minn. I have long believed, as has Aub, that the loss of calcium from the skeleton in hyperthyroidism is not to be explained by increased activity of the parathyroids if for no other reason than that the level of calcium in the blood has never been found elevated. The observation of Drs. Puppel, Klassen and Curtis that calcium is excreted differently in toxic goiter, as compared to exophthalmic goiter, provides further support for the contention of Plummer that these two conditions are distinct entities. However, the evidence presented for a difference in the calcium balances is not entirely satisfactory, for the reason that the basal metabolic rate in the cases of toxic goiter was lower than in the cases of exophthalmic goiter. It would be desirable to compare patients with comparable basal metabolic rates.

DR. GEORGE M. CURTIS, Columbus, Ohio. Our determinations of the calcium balance of patients with thyroid disease have gone hand in hand with our studies of iodine balance. Ten years ago we set out to determine the total iodine balance in patients with hyperthyroidism. After the development of three successive methods for the biologic determination of iodine this has been accomplished with fifteen patients, the majority having thyroid disease. At the same time we determined the total calcium balance. We wished to compare the two owing to the close physiologic as well as clinical relations between the thyroid and parathyroid glands. A part of these combined studies have been reported (Puppel, I. D., and Curtis, G. M. Calcium and Iodine Metabolism in Thyroid Disease, *Arch. Int. Med.* 58:957 [Dec.] 1936). Others are being reported. It has been thought that exophthalmic goiter and toxic nodular goiter are two diseases. Nevertheless, some authors think that they are the same disease, the one representing a more acute manifestation of hyperthyroidism and the other a more chronic and hence more insidious form. The results which Dr. Puppel has presented reveal a difference between the calcium metabolism of exophthalmic goiter and toxic nodular goiter. Admittedly, this is a

small series on which to base conclusions, nevertheless it is indicative and in accord with the work of others. The two patients with toxic nodular goiter had a lower average basal metabolic rate  $+28$  per cent. The three with exophthalmic goiter had a higher rate, averaging  $+40$  per cent. Nevertheless, there appeared to be a difference in the management and utilization of calcium in the two diseases. Moreover, the iodine balance of these same patients revealed differences, giving further ground for regarding the two diseases as differing. The two patients with toxic nodular goiter showed a greater increase in the negativity of the iodine balance than the three patients with exophthalmic goiter. This in itself may not be so significant. Nevertheless, the increased excretion of iodine was greater in the urine of the patients with toxic nodular goiter and greater in the feces of the patients with exophthalmic goiter. In all we should consider these metabolic differences as indicative of corresponding differences between the two diseases. Comparing the disturbed iodine metabolism of patients with hyperthyroidism with the disturbed calcium metabolism of patients with hyperparathyroidism reveals a striking similarity.

#### Percutaneous Absorption of Estrogenic Substances by the Human Female, with Especial Reference to Growth of the Breast Induced by Local Application of Estrogenic Ointments

DR. CYRIL M. MACBRYDE, St. Louis. Several workers have produced local and general effects on the animal body by application of estrogenic substances to external surfaces. The application of appropriate amounts of the substances to any part of the skin has resulted in estrous changes and in mammary and uterine growth in certain spayed animals. DeFremery of Holland has reported that the best production of mammary growth in the virgin goat is accomplished by the application of estrogen directly to the skin of the udder. There are few studies of the effects of percutaneously applied estrogen in the human female and there are no reports of the effect of estrogen directly applied to the breast to induce mammary development. Studies were performed on three women lacking mammary development and exhibiting signs of hypogonadism. Estrogenic ointments were found to induce unilateral mammary growth when only one side received applications of the active material and the other side was treated with the inactive ointment base. The results are shown by caliper measurements and photographs. Vaginal smears changed from inactive to the active estrous state, and characteristic changes were noted in the vulva as the result of the percutaneously absorbed estrogen.

#### DISCUSSION

DR. PAUL STARR, Chicago. I wonder whether Dr. MacBryde mentioned some work by Hans Selve on mechanical stimulation of the breast in order to produce lactation. Is it possible that the factor of mechanical stimulation of the breast was not thoroughly controlled? It was dramatically shown by Dr. MacBryde that after injection treatment was discontinued atrophy was extremely rapid. Was that also true after the injection treatment?

DR. SAMUEL SOSKIN, Chicago. Dr. MacBryde's photographs are convincing. I do not think the members need doubt that he produced the results he reported. Nevertheless, I think it should be mentioned in a meeting of this sort that, while it may be permissible to produce a desirable effect by the use of estrogenic substance in a patient whose ovarian function is decreased or absent, one should not transfer such experiments to women with normal ovaries. It is well known that the prolonged use of small doses of estrogen may result in ovarian atrophy. It is also known that with larger doses one can get luteinization of the ovaries, which results in sterility and other phenomena. Therefore, one should be cautious about considering the use of such therapy in women in whom one wishes to preserve or improve ovarian function.

DR. CYRIL M. MACBRYDE, St. Louis. My work was purely experimental and I hope the procedure will not be introduced into general practice until a great deal more study has been done. The limitations and dangers of estrogen therapy by injection have not yet been clearly defined. In two patients who received the treatment I felt from my previous thorough study that there was probably no active ovarian tissue and so there

was no danger of injuring any possible gonadal function. In the third patient, who had some ovarian activity, I undertook the experiment with a great deal of trepidation. She has improved generally and has suffered no ill effects. However, I agree with Dr Soskin that the use of estrogen in normally menstruating women and women with presumably normal ovaries may have great potential danger, especially with large doses such as I used. In answer to Dr Starr about the effect of manipulation, I may say that as far as it was possible to determine there was exactly the same amount of mechanical stimulation on the two sides, but the breast which received the estrogenic ointment always grew at a much more rapid rate than the control breast. It is true that the breast will regress in size markedly and quickly after discontinuance of either injection orunction. Whether treatment with the ointment causes a persistence in size of the breast for any greater length of time than the injection treatment I am not sure as yet.

#### Urinary Excretion of Androgens Following the Injection of Testosterone Propionate

DRS E PERRY MCCULLAGH and J M RUMSFORD and W KENNETH CUYLER, MA, Cleveland. About 100 assays for urinary androgens are reported for sixteen men with hypogonadism and seven normal men. Single assays have been done in one group following single injections of varying doses, and the ratio of excretion to injection shown. Repeated assays for the same persons appeared to demonstrate diminished rates of excretion as injections continued. Single injections followed by daily assays for hypogonadal persons showed a prompt rise in excretion and a gradual fall to normal. With single doses of from 5 to 10 mg the excretion of androgen rises to near or to within the lower range of normal falling to previous levels within one or two days. With larger doses the elevation is much greater. With doses as high as 100 mg, relatively normal levels of excretion may be maintained for about five days. Single injections in a normal person caused a prompt rise followed by a distinct depression to below normal and finally a recovery of the original excretion rate in four or five days. If excreted androgens are calculated as androsterone, it is found that the amount of androgen which can be recovered from hypogonadal persons on the first day following injection of testosterone propionate is from 20 to 50 per cent of the injected quantity, whereas, if assays are done each day for five to seven days, quantities varying approximately from 25 to 75 per cent of the injected substance can be recovered.

#### Variations in Genital and Somatic Development with Bilateral Cryptorchidism

DRS W O THOMPSON and N J HECKEL, Chicago. A study has been made of eleven males from 15 to 29 years of age with bilateral cryptorchidism. In no instance was somatic development completely normal. When both testes remained within the abdominal cavity there commonly resulted infantile genitalia, a high pitched voice, long extremities, broad hips and absence of hair on the face and body. This was not uniform, as demonstrated by a normal-size penis in two cases in which neither testis could be palpated. In one patient with bilateral intra abdominal testes genital growth was produced with anterior pituitary like principle. Usually, however, growth could not be produced in such instances. Spermatogenesis was not observed in any patient, either before or during treatment with the anterior pituitary-like principle. Testes in the inguinal canal are more capable of function than those in the abdomen as demonstrated by frequent growth of the genitalia in such instances, with and without administration of the anterior pituitary like principle. Both testes can be completely normal only when they are in the scrotum. However, the interstitial cells may show a surprising degree of function even though both testes remain within the abdomen.

#### DISCUSSION

DR PAUL STARR, Chicago. There seem to be a number of variants, one of which is the factor controlling the response of the testes to the substance, evidently specifically suited to stimulating it when the testis is normal. Do I understand

that these studies indicate that the location of the testis in the abdomen renders it unlikely to respond to the anterior pituitary like principle? How is it possible, then, that in children in whom the testis is in the abdomen the material produces the onset of puberty and the descent of the testis? If that criticism is just, is the difference in responsiveness of these patients a matter of age rather than of location of the testis?

DR SAMUEL SOSKIN, Chicago. I should like to ask the authors to discuss some work reported six or eight months ago by T W MIMPRISS (Treatment of Retention of Testis, *Lancet* 1 533 [March 5] 1938), who presented evidence to show that if the testes were intra-abdominal the use of anterior pituitary-like principle, if it did not cause them to descend, might actually cause them to atrophy.

DR E P MCCULLAGH, Cleveland. The authors have come to the conclusion that the reason for failure of response of the testes in these patients to injection of anterior pituitary-like principle is that they lie in an abnormal position in the body. This may be true in some degree, but I believe that an alternative explanation might be considered. Two types of relatively severe hypogonadism are seen clinically. In one type the remnant of testicular tissue can be detected in the scrotum, and all the symptoms can be accounted for on a basis of deficiency of activity of the testes themselves. In the other there may be obvious testicular hormonal deficiency, but, in addition, there are other signs which cannot be accounted for purely on a basis of testicular hormonal failure. The authors' cases of cryptorchidism are of this latter type. It seems fair to assume that, if the mechanism which is involved in the bringing of these testes into normal position is severely damaged, the testes may be subnormally developed as well as lying in a markedly abnormal position. Under such circumstances, may it not be possible that the development of the testes themselves may be altered by deficiency in this mechanism? If this is true and the mechanism which causes testicular descent is more nearly normal, then the testes should be more nearly normally developed, as well as lying closer to their normal position. Therefore, I suggest that the lack of response in cases of severe cryptorchidism might be more intimately connected with a deficiency in the factor which causes their development and descent than to actual position in the body per se.

DR CLYDE L SEARINGHAUS, Madison, Wis. I should not want to minimize the position of the testis in its biologic response. I think there is an analogy in the position of the ovary. I have observed cases of primary amenorrhea or marked underactivity of the ovary which responded well to pituitary gonadotropic material. I have observed other cases in which there was little ability to respond to treatment with the same preparation. The ability to respond was measured by the intensity of the vaginal smear. Here one is dealing with an objective thing, the menstrual cycle, and it cannot be a matter of position because the ovaries function entirely within the abdomen. It must be something else, the ability of the gonad to respond to a given stimulation. Why do some ovaries never respond more than a little? There must be a similar problem in the testes. Unfortunately in the testes there is nothing to act as a measure of responding intensity except the size of the external genitalia.

DR W O THOMPSON, Chicago. I am sure Dr Starr did not understand what I said about location. In the boys I presented in whom we got a response to stimulation, one or both testes were either in the inguinal canal or deflected over the external oblique muscle a position in which we think they are more responsive to stimulation. Mimpriss recently wrote an interesting article on the whole problem of undescended testes. I do not know whether his evidence that the anterior pituitary-like principle causes atrophy if the testis is incapable of response is adequately supported by the data he presented. One of the most interesting things that Mimpriss pointed out is that the only testes which came down with treatment were those which would have come down spontaneously at the time of puberty if no treatment had been given. We have come to that conclusion.

independently as the result of a large number of observations over a period of about three years. Dr McCullagh questioned the wisdom of concluding that the position of the testis accounts for its failure to respond to administration of gonadotropic substance. With this point of view I heartily agree. It is possible that the testes remained within the abdomen because of lack of development, or they may have undergone atrophy or been replaced by scar tissue as a result of remaining within the abnormal environment of the abdomen for such a long period. It would therefore be unwise to conclude that position alone was the responsible factor. Rather, the changes associated with or resulting from long-standing position of the testes in the abdominal cavity produce the results observed. Dr Sevringhaus pointed out that in patients with underdeveloped ovaries striking response may be observed after the administration of the gonadotropic factor from the pituitary. He suggested, therefore, that not too much attention be paid to the position of the testis as a cause of failure of response. However, the situation is different in the two instances. The ovary is normally located in the abdominal cavity, while the testis is normally located within the scrotum. Absence of the normal environment is presumably the determining factor. It has been repeatedly demonstrated in both man and animals that, when testes which normally are in the scrotum are placed in the abdominal cavity, atrophy occurs and spermatogenesis ceases. In many instances normal size and function may be resumed if they are again placed in the scrotum.

#### Is the Potassium Tolerance Curve Specific for Detecting Adrenal Cortical Insufficiency in Disease?

DRS JAMES A GREENE and H LEVINE, Iowa City. The potassium tolerance curve has been advocated as a method for detecting adrenal cortical insufficiency. Before it can be accepted as a diagnostic criterion its specificity for adrenal cortical insufficiency must be ascertained. We have obtained the potassium tolerance curve in a variety of maladies, and it was altered in certain cases of asthenia, bromism and edema. The first two conditions may be confused with early Addison's disease. Therefore the similarity of the manifestations of Addison's disease and bromism and the possible causes for alteration of the potassium tolerance curve in association with conditions other than Addison's disease are discussed.

#### DISCUSSION

DR PAUL STARR, Chicago. Is it necessary to control the sodium chloride balance in these patients for some time before the test is given or is it sufficient to assume that a diet high in salt will do? Is it possible that patients with bromism had had an abnormally high potassium intake?

DR JAMES A GREENE, Iowa City. I cannot answer that question. In some cases of induced bromism we had to reduce the salt intake in order to induce bromism. In others we did not. Some patients were on a salt-free diet and others were on a general diet.

#### Measles Encephalitis

DRS M G PETERMAN and M J FOX, Milwaukee. It is our opinion that measles encephalitis, or encephalomyelitis complicating measles, is an entity as distinct as is the encephalitis following vaccination against smallpox. We believe that the disease is an acute inflammatory lesion of the brain caused by an attenuated virus of measles which has accumulated in the brain in certain patients. This entity must be kept in mind by every physician who deals with measles. It may easily be recognized if it is kept in mind. On or about the fourth day after the appearance of the rash the child suddenly becomes drowsy, lethargic or comatose or a convulsion may develop. Examination then reveals a comatose child with usually some degree of rigidity of the neck, dilated pupils and exaggerated reflexes. The blood count usually shows polymorphonuclear leukocytosis, the spinal fluid, pleocytosis, usually lymphocytic, an increase in globulin and a colloidal gold curve with the greatest change in color in the middle or meningeal zone (0123321000). The sugar content of the fluid is usually normal or elevated unless that of the blood is low. No further examinations are necessary or advisable to establish the diagnosis. There can be no question of interpretation of this clinical picture. In the matter of treatment we are convinced that good nursing care and symptomatic

treatment constitute the limits of present therapy. As in polio myelitis and all virus diseases, when the earliest symptoms are recognizable the virus has already completed an irreversible reaction with the nerve cells. There is no specific treatment, and the convalescent serum of measles cannot possibly be of value.

#### DISCUSSION

DR JAMES A GREENE, Iowa City. I should like to ask Dr Peterman if he thinks the disease represents a secondary infection or a complication of measles. I studied mumps and found that encephalitis as a complication of mumps occurred frequently. I wonder whether the cases described were of the more severe type and whether the milder type was overlooked.

DR LEE GOSHAY, Cincinnati. In view of the therapeutic results obtained by Dochez and his associates in distemper and by Tamura in venereal lymphogranuloma I do not think Dr Peterman's therapeutic pessimism should be accepted in its entirety. There are both specific and nonspecific modes of treatment that modify the course of some virus diseases. I know it is often stated that treatment is of no avail in any virus disease but I do not think this should hamper physicians in future trials of therapeutic procedures. I should like to ask the authors whether they think the recent use of human convalescent serum or of human placental globulin in attempted prophylaxis of the disease may have played any part in the apparent recent increase in the incidence of measles encephalitis.

DR M G PETERMAN, Milwaukee. It seems to us that measles encephalitis is a definite entity, that is the virus of the disease has invaded the nervous system. In that respect we may say it is a primary disease, and yet since it develops only with measles it must be a secondary infection. It apparently results from the same virus with perhaps an accumulation in the brain. We have seen mild meningitis with all the mild infectious diseases. Scarlet fever often has its onset with convulsions. Pneumonia may be associated with meningitic symptoms, and there may be changes in the spinal fluid which promptly subside, and we consider the meningitis a secondary symptom complicating pneumonia, whereas in measles encephalitis we consider that the virus has produced the disease and then a secondary extension has produced another disease of the central nervous system. I doubt that any case of typical complete measles encephalitis could be overlooked because of the severity of the symptoms and the duration of the disease. I doubt that the meningeal irritations or the milder cerebral symptoms can be classified as encephalitis because in all contagious diseases, particularly those mentioned as well as mumps some mild cerebral involvement may occur. Young children particularly have cerebral involvement with many infections in which there is high fever. I am pessimistic about the use of convalescent serum, probably as an attempt to counteract the scientific salesmen from the convalescent serum centers. I have heard physicians remark 'I had to give convalescent serum because the people demanded it. I think it should be understood that convalescent serum is of no value and has had no value in preventing encephalitis. After all only approximately 60 per cent of the persons coming in contact with measles will have measles, and that depends entirely on the intimacy and the duration of exposure. It is difficult to evaluate statistics on prophylaxis against measles.

#### Focal Epileptogenic Lesions of Birth and Infancy and Their Eventual Radical Treatment

DRS H M KEITH and WILDER PENFIELD, Montreal. This is a clinical study of patients who had craniotomy because of focal epileptogenic lesions which could be traced to injury at birth or in early infancy. The patients were carefully studied clinically, electrical explorations of the cortex were carried out at operation, and an attempt has been made to diagnose in retrospect the type of lesion that occurred at birth. Certain types of injury were found as follows: 1 Old fracture of the skull laceration of the brain, hemorrhage and scar formation. 2 Subdural hemorrhage with resultant subdural adhesions and convolutional atrophy. 3 Cerebral atrophy due to thrombosis of a large artery. 4 Focal atrophy due to compression ischemia. 5 Diffuse atrophy due to natal asphyxia. 6 Adhesions and convolutional atrophy due to infantile meningitis.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1924 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Synovial Sarcomas**—From a study of five personal cases of synovial sarcomas and a review of the literature, Berger concludes that histologically only those tumors should be considered of synovial nature which present one or more specific features of the normal synovial tissue. From a topographic point of view his cases show that synovial sarcomas may arise outside of and far from articulations, in the midst of soft tissues where they originate in serous bursae normal or irregular from a purely anatomic point of view. With regard to evolution, synovial sarcomas are highly malignant tumors, although they seem at first to grow slowly. Synovial sarcomas of serous bursae apparently take a more rapid course than those of articulations. Recurrences develop in almost all patients operated on. Death is generally due to pulmonary, exceptionally to cerebral metastases. Definite cure is exceptional and can be obtained only by early removal. Therapeutic measures should therefore be prompt and radical.

**Alcohol and Trichinosis**—Since there are reports that alcoholic beverages taken liberally with trichinous meat offers protection against infection and since the use of generous quantities of alcoholic liquors has been advised as therapy in trichinosis, McNaught and Pierce investigated this problem by *in vitro* studies and by experimentation on rats. Their conclusions are that while alcohol has little direct action on trichinella larvae *in vitro* and only halves the number of larvae which develop in the rat after a fixed dose of free Trichinella

is ingested, it reduces the severity of the infection by 80 per cent if the alcohol is taken at the same time as is trichinous meat. A single dose of alcohol taken together with trichinous meat reduced the number of Trichinella that encysted in the muscles of rats by 80 per cent, but when alcohol was taken in large quantities over a period of seven weeks during the maturation, larval bearing, migrating and encysting stages of the parasites it gave no protection. *In vitro* experiments suggest that this protective action is due to the fact that alcohol interferes with the digestive liberation of encysted Trichinella. Experiments on rats verify this. The daily ingestion of from 6 to 8 cc of absolute alcohol per kilogram of rat did not appreciably raise their blood alcohol values. Rats infected with Trichinella showed the highest blood eosinophilia during the third week of infection.

**Complement Fixation Reaction in Tuberculosis**—Kolmer and Mahoney performed tuberculosis complement fixation tests on the serums of 408 tuberculous individuals, of these 637 per cent gave positive reactions with an 8 year old antigen of partially degenerated human bacilli prepared and tested by the Kolmer method. The presence or absence of fever at the time the specimens of blood were collected had little or no influence on the results since positive reactions were obtained in sixty-three of the febrile and 641 per cent of the afebrile cases. Four of twenty-five serums from syphilitic nontuberculous donors gave positive tuberculosis complement fixation reactions presumably due to the fixation of complement by syphilitic antibody with the lipoids and waxes remaining in the partially degenerated bacilli of the tuberculosis antigen. The authors recommend the performance of the Wassermann test on all serums submitted for the tuberculosis complement fixation test, when the former gives a positive reaction, great caution is required in the interpretation of a positive tuberculosis reaction.

\*Practical Method of Analyzing the Precipitating Factors Producing Peptic Ulcer E. J. Callahan and D. W. Ingham Saratoga Springs N. Y.—p. 751

**Factors Producing Peptic Ulcer**—It is evident to Callahan and Ingham from the cursory review of the current theories that despite criticism against the neurogenic origin it is yet the most constant etiologic factor in peptic ulcer. The food habits of a patient with ulcer must be carefully studied, as a well arranged nonirritating low residue diet is the foundation on which treatment is built. Although studies in heredity have not clearly demonstrated that there is a transmitted tissue susceptibility to peptic ulcer, this may be assumed because there seems to be a correlation between body build, personality and other qualities and this common gastrointestinal lesion. The authors employ an uncomplicated office procedure in their practice of gastro-enterology. They have constructed two charts each containing an equilateral triangle the sides of which are represented by the letters A B C. The hereditary factor is represented by A, the psychogenic factor by B and the food factor by C. One chart represents the diagnostic or analytic chart and is constructed with the apex of the triangle downward, which symbolizes imbalance. This demonstrates to the patient the mechanism of his recurrences and recurrences by the ease with which this triangle is thrown

off balance. After a routine history and physical examination have been completed and a clinical diagnosis of peptic ulcer has been confirmed by fluoroscopic and x-ray examination, the first chart is shown to the patient. The cause of peptic ulcer may be projected on the sides of the triangle. The A side of the triangle is dismissed by explaining to the patient that he has an inherited susceptibility to peptic ulcer. The B side of the triangle may be divided into four main divisions: long illness in the family, financial troubles, unfaithful spouse and unexplained worry. The C side of the triangle, although the food habits of people with and without peptic ulcer are practically the same, is necessary to complete the hypothesis. After this survey has been made with the patient, the psychogenic factor is considered. The particular inciting agents responsible for the presenting complaint are elicited and identified. Careful and repeated questioning will reveal the psychic stimulus which by constant repetition produces the onset of his disease or a recurrence. A second chart is designated the therapeutic chart, in which the triangle is constructed with the base downward representing stability. The sides of the triangle are labeled in the same manner. Thus, the one factor which is within control is the food factor, hence it has been established as the base of the triangle. The remaining two sides are explained as follows. On the assumption that there is a hereditary trend in peptic ulcer the patient must accept this and try to live within this limit of ability. For example, if he is 25 per cent disabled by his disease he must strive to live 100 per cent of the 75 per cent and not more. The patient is urged to seek possible solutions for the anxieties which he may have. If the problem is of such magnitude that it cannot be dismissed with ease, he is cautioned to accept a philosophic view and do the best he can each day, be honest with himself and avoid fatigue and worry.

### Copper and Iron in Anemia from Therapeutic Malaria

—In the course of their work on the treatment of dementia paralytica with malaria Schube and Prescott often observed that the secondary anemias which almost invariably resulted were exceedingly alarming not only in their intensity but also in the persistence with which they remained after the termination of the malaria, and irrespective of the institution of ordinary iron or liver therapy. The combination of copper with iron was instituted in some of these cases, and the combination enhanced the formation of hemoglobin and erythrocyte. This was well illustrated in cases of secondary anemia of unknown origin, as the combination increased the hemoglobin and erythrocytes quite consistently in most instances. The hemoglobin and erythrocytes were both depressed in secondary anemia induced by malaria in dementia paralytica patients but untreated with

copper or iron and increased only many weeks after the termination of the malaria. When ferrous iron was administered regularly from the time of the malarial inoculation to the return of the blood picture to normal, the average curves of depression and the return of the blood elements to normal were approximately the same. But in the same type of patients when copper and iron were regularly administered from the time of the malarial inoculation to the return of the blood picture to normal the curve dropped slower, and before it had dropped half the distance of the other two groups it began to rise again and reached normal much sooner than those of either group. The time from the first temperature elevation to the lowest hemoglobin and erythrocyte counts was usually shorter, and the return to normal was generally more rapid. This lessened severity of the anemia coupled with the fact that it was more difficult for the malaria to produce the anemia and the fact that the erythrocyte counts and hemoglobin were rapidly restored to normal by means of copper and iron would indicate that these minerals are of value in combating the anemia incurred by malaria. Iron and copper did not interfere in any way with the expected therapeutic benefit from the malaria with the temperature rises or with the action of trypanamide. The authors feel that copper and iron can be used with impunity in dosages much larger than the ones (32 mg of ferrous iron and 1 mg of copper orally in capsules) they used. It is highly probable that larger doses would be more satisfactory. They believe that their work indicates that the reticulo endothelial system of man can be stimulated to such an extent that it can minimize the devastation wrought in the blood stream by malaria. It also indicates that the malaria did not materially affect the reticulo endothelial system of the cases studied and thereby intensify the anemia produced by direct erythrocyte destruction.

**Hemorrhoids**—Krause injected from 5 to 10 minims (0.3 to 0.6 cc) of 5 per cent phenol in sterile olive oil or 5 per cent quinine and urea hydrochloride in the treatment of seventy five cases of hemorrhoids. The ages of the patients ranged from 16 to 86 years. The injection was made around and above the hemorrhoid just beneath the mucous membrane. Chronic con-

stigation was complained of generally. Bleeding, pain and protrusion was a universal complaint. Itching occurred in 60 per cent of the cases, of which ten cases showed pruritus. The interval between injections varied from five to ten days, bleeding persisted in every case until the last ulcerated site had disappeared, for this reason the ulcerated spot was always chosen for the first injection. Symptoms of pain, bleeding and protrusion invariably improved following the first and second injection. Pruritus with itching was the most resistant condition and was the last to disappear. The patient is cautioned not to strain or defecate within from twelve to twenty-four hours after the injection. Seventy-one patients were ambulatory with normal activity restricted.

**Amphetamine in Depressed Psychoses**—Dub and Lurie selected, for treatment with amphetamine sulfate, forty-eight depressed female patients from a service of about 1,500 patients at Longview Hospital because of their pronounced depression as revealed by their mood, speech and actions. The ages of the women ranged from 18 to 75 years. They had been institutionalized for from ten months to twenty-six years. The patients were given 5 mg of amphetamine sulfate twice a day. The first dose was given at breakfast and the second with the noon meal. To those patients who refused to take the medication the drug was mixed with the food. In certain cases the dosage was increased to 10 mg twice a day. This was done if there was no improvement after a week's trial on the smaller dose. The medication was continued for three weeks. A lactose placebo was then substituted without the knowledge of the attendants or patients. The placebo was continued for three weeks, after which no medication was given for two weeks. Following this rest period the patients were again given the placebo for four weeks, after which amphetamine sulfate was again substituted and continued for six weeks. The effects of the treatment on the appetite, thirst, pulse, sleep, mood and psychomotor activity were recorded daily. Weight and blood pressure were recorded weekly. Forty-two of the women showed definite improvement when amphetamine was administered. A patient was considered benefited if she showed improvement in at least two of the following criteria: weight, cooperativeness and psychomotor activity. During treatment with the placebo, five patients became so violent that they could no longer participate in the experiment. Only five of the remaining forty-three patients maintained their initial improvement while thirty-eight relapsed when the lactose placebo was substituted for the amphetamine. During the rest period of two weeks, three more patients were lost to the experiment, one through discharge as apparently cured and two because they became violent. Of the remainder six remained improved while thirty-four remained unimproved. When the patients were again placed on placebo treatment only three held their gains. In other words, at the end of this period 92 per cent of the patients in this series were practically in the same mental condition that they had been in at the beginning of the experiment. But when amphetamine was again administered an immediate and striking improvement was observed in thirty-five, while only six failed to respond. An equally striking slump was observed when the amphetamine therapy was again discontinued, the results being practically the same as

those during the rest period. The best response was obtained in the paranoid and patients suffering from cerebral sclerosis, while the patients with dementia praecox responded the least. The duration of the disease seemed to have no bearing on the results obtained. Age, however, seemed to be of some significance as the women from 41 to 60 years of age showed the highest incidence of improvement.

Amblyomma Philippi New Tick from Texas and Mexico with a Key to Known Species of Amblyomma in the United States (Acarina Ixodidae) R A Cooley and G M Kohls—p 44

**Odor in Manufacture of Kraft Paper**—There are three types of obnoxious odors due to the process of manufacturing kraft paper. Dalla Valle and Dudley list them as (1) hydrogen sulfide, (2) volatile organic sulfur compounds and (3) chemical smoke containing sodium sulfate, sodium sulfide, traces of hydrogen sulfide and quantities of carbon and organic materials. Hydrogen sulfide is formed and released to the atmosphere at smelter furnaces where molten sodium carbonate and sodium sulfide are dropped into water and in the separator building in which this solution is filtered. The treatment of the fresh wood chips by the digester liquor containing sodium sulfide brings about the formation of many unknown volatile organic sulfur compounds. At nearly all points of the process at which the pulp is handled after the digestion, certain of these ill smelling volatile organic compounds are liberated. The greatest volume and concentration of these compounds are released from the turpentine condenser as steam is led from the digester tanks and when the pulp is blown from these tanks with the release of large quantities of steam containing many volatile constituents. The large quantities of smoke which are released through exhaust stacks release large amounts of sodium carbonate in a colloidal state. Although sodium carbonate in a pure state is odorless, much uncarbonized organic matter accompanies these particles, traces of hydrogen sulfide and various volatile oils of unknown composition. These organic materials, which are at least partially adsorbed on the colloidal particles of sodium carbonate, give rise to the peculiar odor when this smoke is blown across the ground. Methods of study are recommended which may lead to the control of the odor-generating processes. The possibilities of electrical precipitators to prevent an excess of chemical smoke are stressed.

**Lipoid Pneumonia in Infants and Children**—Bromer and Wolman studied twenty-seven cases of lipoid pneumonia at the Children's Hospital. Twelve of these were found in a series of 137 consecutive necropsies. Of the twenty-seven

patients, twenty-two died and postmortem studies were performed on twenty. The nature of the pulmonary lesion was recognized in only one, although roentgenograms of the chest were made of sixteen. In two thirds of the cases the pneumonia was associated with some sort of constitutional debility (prematurity, rickets, congenital syphilis, microcephaly, infantile scurvy, mongolism, spastic diplegia, amyotonia congenita, *intestinal malformations or congenital cardiac defects*). This indicates that physical weakness must be considered as an important predisposing factor of lipid pneumonia. Retardation of growth and poor nutrition, attributable in most instances to the constitutional disturbance rather than to the pneumonia, was present in twenty-one patients. The most common single symptom was chronic cough, present in six patients. As a rule the chest on physical examination seemed clear, although in a few instances minor signs were observed over the consolidated areas. None of the patients had a positive tuberculin test. The distribution of the pulmonary lesions at necropsy clearly indicated the exogenous origin of the lipid. The posterior dependent portions of the lungs, and especially the perihilar regions, were always affected. The right lung was more involved than the left, possibly because of the straighter course of its main bronchus. The nodules and solid lobules of lipid pneumonia were confluent, grouped or widely separated. Bands of scar tissue were sometimes present. The bronchopulmonary nodes were involved in a few instances. The roentgenograms of this series of patients, some showing a wide distribution, others an extremely slight involvement, emphasize the diverse x-ray variations. The pulmonary lesions can be classified as mild, moderate or severe, according to the extent of the involvement. This division is not dependent on the time that has elapsed following the aspiration of the oily substance or on the kind of oil aspirated. Experimental production of lipid pneumonia as reported in the literature suggests that cod liver oil causes an acute pneumonia which, after subsiding, leaves residual foci, whereas liquid petrolatum produces a more chronic reaction, which should result in an unchanged appearance in the serial roentgenograms. The extent of involvement depends on the quantity of oil in the lung regardless of whether it is aspirated in a single large amount or in repeated small quantities. The roentgenograms of the patients having only a mild involvement show an increase both in degree of density and in extent of the hilar shadows. The linear markings of the pulmonary fields are more exaggerated than normal. If small scattered areas of increased density are present they are usually situated along the descending branches of the right bronchus. The cardiac shadow obscures the left hilar markings. In the group with moderate involvement there is greater density of the perihilar shadows with widening in all directions. The dense shadows spread more or less homogeneously in all directions from the hilus. In several cases the left lung was unaffected. In the severe cases the perihilar shadows spread well out toward the peripheries of the lungs, although usually a clear zone is left between the dense shadow and the walls of the chest. As the child grows, this clear zone becomes wider unless the aspiration of oil continues. The edges of the lesions are either sharply demarcated or feathery. A definite lobal pneumonia shadow is not seen unless nonlipid pneumonia is present simultaneously. Coincident inflammation of the lungs was found frequently at necropsy. This may develop in the mild, moderate or severe cases. Serial roentgenograms are necessary to recognize its development and also to establish the chronicity of the process when no pneumonia supervenes. The positive diagnoses made in the five patients of the series who are still living were based on the x-ray observations, typical of severe involvement and proved chronic by serial roentgenograms.

**Bronchogenic Carcinoma**—Howes and Schenck report the pathologic features of eight fatal cases of bronchogenic carcinoma submitted to postmortem examination. Of the 737 new cases admitted to the Brooklyn Cancer Institute during 1937 there were seventeen of bronchogenic carcinoma, an incidence of slightly less than 3 per cent. In larger series of cases, bronchogenic carcinoma shows an incidence as high as 10 per cent of all cancers. The cause is still unknown, but

it is generally conceded that some form of chronic pulmonary irritation accounts for the development of the neoplasm in most instances. The symptoms are not unlike those observed in other chronic pulmonary diseases, especially tuberculosis, bronchiectasis, pulmonary abscess, mediastinal tumor and fluid cyst of the lung. X-ray study, including the instillation of iodized oil, reveals the true nature of the pulmonary pathologic changes in the majority of cases. In the presence of pleural fluid which obscures the underlying markings of the lungs, overpenetrated films or Potter-Bucky exposures should be made. With a mass in the region of the thoracic aorta, kymographic studies are indicated to exclude the possibility of an aneurysm. A necrotizing process in the lung, portrayed roentgenologically, does not exclude the possibility of a carcinoma which has undergone necrotic liquefaction. A negative bronchoscopic examination does not preclude the diagnosis of a primary pulmonary tumor, especially when the involvement is in the upper lobes or located in the finer bronchi. If the diagnosis is in doubt, biopsy of an available enlarged lymph node or mass should be performed. A metastatic process may present the first symptom of the disease. Clinically the skeletal system, regional lymph nodes and pleurae are the sites of metastatic predilection. In the osseous system the pelvis, femur, spine, skull and ribs are the more susceptible regions. Roentgenologically the skeletal lesions show osteolytic, osteoblastic or combined types of involvement. The majority of patients with bronchogenic carcinoma die within one or two years. The present recognized forms of treatment are irradiation and surgery. Irradiation with the present technic is at best palliative, surgery offers hope in selected cases. Microscopically three types are recognized—the squamous carcinoma, the adenocarcinoma and an undifferentiated group.

**Diagnosis and Treatment of Anemias**—Osgood states that the diagnosis of anemia should always be based on an accurate erythrocyte count and hemoglobin determination, since the symptoms of pallor, weakness, dizziness, shortness of breath and edema may be produced by other diseases and are absent in some cases of anemia. It is important to determine the reticulocyte count, the icterus index and the urobilinogen excretion in the urine in any case of anemia. If the reticulocyte count is above 4 per cent it indicates an increased rate of erythropoiesis and if below 4 per cent it indicates a decreased rate of erythropoiesis. An icterus index above 6 or the presence of clinical jaundice with a positive urobilinogen test in a dilution of 1 to 20 in the urine indicates an increased rate of hemoglobin destruction within the body if disease of the liver or obstruction of the biliary tract can be excluded. An icterus index below 4 indicates a decreased rate of erythrocyte destruction. Anemias should be classified as macrocytic, hypochromic, microcytic or normocytic by an accurate determination of the color, volume and saturation indexes. There is no longer a place for the old terms 'primary' and 'secondary' anemias, since all anemias are secondary to some usually determinable cause and intelligent treatment can be given only when this cause is determined and removed. Correct diagnosis is a prerequisite to intelligent therapy.

**Clinical Observations with Synthetic Estrogen**—Winter and MacGregor treated forty-five patients complaining of symptoms referable to an endocrine disturbance and six others in whom it was considered desirable to inhibit lactation with the synthetic estrogenic compound diethylstilbestrol. The responses obtained were similar to those which would have been expected from treatment with natural estrogen. Oral administration of the synthetic substance was found to be as effective as intramuscular therapy. Some of the patients experienced slight nausea during the treatment, but in only one was the treatment poorly tolerated.

**Therapy with Synthetic Estrogen**—Loeser used a synthetic estrogen (diethylstilbestrol) in the treatment of fifteen patients with minor degrees of ovarian insufficiency, climacteric disorders, dysmenorrhea, hypo oligomenorrhea, secondary amenorrhea, ovarian insufficiency and pruritus vulvae. The synthetic estrogen shows such definite estrogenic effects that it has a good substitution action in various forms of ovarian insufficiency. In six of the fifteen cases for which it was used, unpleasant secondary effects such as nausea or vomiting were produced.

**Agglutination Reaction in Typhoid Carriers**—Murray and Partner performed Widal tests on twenty-five known typhoid carriers. Eleven of these carriers gave negative blood agglutination reactions at a time when the organism of typhoid could be recovered from the stools. The authors state that a greater number of carriers will be detected if bacteriologic studies of the stools are always made. In this connection attention may be drawn to the long persistence of the passage of organisms, one person in the series dates the original infection to 1910.

**Horse Serum in Blood and Cerebrospinal Fluid**—Burtenshaw tried to find what proportion, if any, of therapeutic serum, administered parenterally to patients suffering from meningococcal meningitis, reached the cerebrospinal fluid. Since there is no simple method of assaying meningococcus antitoxin, it was thought that a test for the presence of the antitoxin-containing horse serum in the body fluids of subjects injected with the serum would furnish at least an indication of the presence of antitoxin. Such a test was provided by an adaptation of the precipitin reaction. Twenty-three patients with meningococcal meningitis and one from whom only a strain of staphylococcus was isolated received meningococcus antitoxin only by parenteral, usually intravenous, injection. Horse serum protein was detected in the cerebrospinal fluid in every one, though its concentration varied greatly from case to case and was always small compared with the simultaneous concentration in the blood. The values of the ratio horse serum in blood/horse serum in cerebrospinal fluid agree well with the observations of Freund for typhoid antibodies. Allott (1938) in a large series of cases, including the twenty-four of this investigation, finds similar variations of sulfanilamide content in the cerebrospinal fluid in spite of equivalent dosage, but in contrast to the behavior of horse serum the sulfanilamide concentration in the cerebrospinal fluid rapidly approximates, during the first twelve hours after administration that in the circulating blood. There is no apparent correlation between age and the permeability of the blood-brain barrier to horse serum, though this barrier may have varied with the intensity of the meningitis. Traces of foreign protein persisted for a long time, both in the blood and in the cerebrospinal fluid. Intrameningeal injections of serum ensure the immediate presence of large amounts of antibody at the site of infection, yet equally striking is the steepness of the drop in serum concentration from the heights reached by intrameningeal dosage. Within one or two days, however large the dose, the cerebrospinal fluid serum content has fallen to the low levels attained by parenteral administration alone.

**Treatment of Endocarditis with Sulfapyridine**—Ellis obtained much improvement in two cases of subacute bacterial endocarditis with sulfapyridine. The pyrexia in the first case was controlled in twenty-four hours by 2 Gm of sulfapyridine. The profound fall in temperature that can be produced by large doses makes the author wonder whether some temperature-reducing mechanism may not be at work other than the mere destruction of organisms. The fall in temperature is at least in part presumably due to a sterilizing of the blood stream, though there is as yet no certain proof of this. Obviously the ideal investigation which must be undertaken is daily blood cultures while the patient is apyrexial under the influence of the drug. As the dosage of sulfapyridine was reduced in the two cases cited, the temperature slowly rose, but it did not reach its former heights until the drug was practically stopped. It may be that there is partial sterilization of the blood, but not of the primary focus of infection, the endocardium. It seems that the mechanical problem of the locked up streptococci is still the stumbling block in the treatment of this type of endocarditis. Sulfapyridine is none the less, as far as the author is aware, the only drug which has ever been known definitely to reduce the temperature and temporarily to improve the clinical condition.

- \*Benign and Malignant Hypertension Their Relations to Kidney E Dicker—p 323  
Primary Abdominal Pregnancy Case M Vastesaegeer and G De Tauf—p 333

**Benign and Malignant Hypertension**—Dicker in discussing the pathogenesis of benign and malignant hypertension, reviews studies of other investigators and describes his own clinical and experimental observations. Summarizing the present status of the question he says that 1 The diminution of the irrigation of one or both kidneys suffices to induce a hypertension of long duration, without renal insufficiency 2 The hypertension that is secondary to renal ischemia does not have a nervous origin but is due to a humoral action 3 The vascular modifications that are observed in a man with benign hypertension and which consist essentially in a thickening of the media are the same as those which can be observed in dogs that have had hypertension for a long time but do not show renal insufficiency, thus they are secondary to hypertension and the late result of the renal intervention 4 Renal insufficiency alone never determines hypertension or anatomopathologic changes of the vessels 5 The necrotic lesions that are pathognomonic of malignant hypertension are the result of renal insufficiency developing unexpectedly in the course of an old hypertension. The kidney being responsible for the hypertension, it can be affirmed that in the last analysis the vascular changes are like wise the result of a renal intervention. Thus it can be seen to what extent the role assumed by the kidney is essential in the pathogenesis of hypertension. It remains to be determined what is the substance (or the complex of substances) which, originating from an ischemic kidney, is capable of producing a definite hypertension either directly or indirectly by means of endocrine products, finally it remains to be seen whether it is the same as that which, in case of renal insufficiency, is capable of bringing about necrosis of the arterioles and of transforming a benign hypertension into a malignant one

- \*Physiologic and Clinical Significance of Peroxidase Action of Blood M Polonovski and M Jayle—p 57  
Cerebrospinal Concussion F Pedrazzini—p 58

**Peroxidase Action of Blood**—In studying the biochemical mechanism of oxidation in human blood, Polonovski and Jayle show that the phenomena of oxidation are dependent on three types of enzymes: the dehydrogenases, the oxidases and the peroxidases. They demonstrate that there exist in human blood, apart from the peroxidases of the leukocytes, two peroxidase systems. The first is the peroxidase system A, its activity is related to 1 cc of plasma and expressed in iodine units (I U). The second is the peroxidase system B, 'the hemoglobin activator of the plasma', it is expressed by the same symbol and is related to 0.1 cc of plasma. In a table the authors compare the values for A and B in several healthy persons and in patients. From the biologic point of view, hemoglobin reveals itself as an animal peroxidase of catalytic action which is in all points comparable to that of vegetable peroxidases and like them capable of playing a part in the biologic oxidations of the tissues. From the clinical point of view, the existence and the pathologic variations of the hydro-alkyloperoxidase of the plasma (A) and of the plasmatic activator (B) of the peroxidase action of the hemoglobin permit certain prognostic deductions. The difference between A and B, which is normally positive, becomes in certain disorders the more negative as the prognosis becomes more unfavorable.

- \*Late Results of Stellectomy in Bronchial Asthma R Leriche and R Fontaine—p 475  
Differential Arteriographic Diagnosis Between Arterial Embolism and Acute Thrombosis R Fontaine and P Branzon—p 479

**Stellectomy in Bronchial Asthma**—From 1926 to 1934 Leriche and Fontaine resorted to stellectomy in fourteen cases of bronchial asthma. In order to evaluate the late results of the operation, eleven patients were followed up for some time

In seven cases in which unilateral stellectomy was performed the asthmatic crises immediately disappeared in two cases but the operation failed in five. Up to the present, the satisfactory results of unilateral stellectomy in one case have lasted for thirteen years (recovery) and in the other the crises, greatly attenuated, reappeared after a period of seven years of complete cessation of the attacks. In four cases of bilateral stellectomy the operation was followed by immediate disappearance of the asthmatic crises. In one case, recovery has lasted up till now (seven and a half years after the operation). In the other three cases the crises reappeared greatly attenuated both in frequency and in intensity. The satisfactory results in the last three cases have lasted from three to five years after the operation. The authors state that the preliminary infiltrations of the stellate ganglion before stellectomy is of value in attenuating or arresting the development of asthmatic crises while the patients are being prepared for stellectomy. Generally, but not in all cases, the patients who have a favorable reaction to the preliminary infiltration of the stellate ganglion have also a favorable response to stellectomy. They point out the dangers and lack of satisfactory results of other surgical treatments (vagotomy or resection of the posterior bronchial plexus) which are resorted to by some authors in the treatment of bronchial asthma. They emphasize the satisfactory results of bilateral stellectomy, especially in intractable forms of bronchial asthma. The operation involves a simple technic and is well tolerated by the patients and is dependable for immediate and late results.

Simulated Pregnancy Case W Neuweiler—p 32

**Treatment of Diarrhea with Salt-Free Diet**—Salomon shows that the treatment of diarrhea has undergone considerable changes in recent decades. Whereas formerly it was the rule first to remove the "materia peccans" by means of purgatives it is now believed that the intestine purges itself sufficiently in the course of a severe diarrhea. The author says that he as well as others have long defended this opinion, because the administration of purgatives in the course of diarrhea may have serious results. He further cites the experiments with tea and fruit juices which he carried out in 1909, the experiences of Heisler and Mora made with the apple cure and other observations. He agrees with von Noorden's opinion according to which the absence of sodium chloride is the essential factor in the fruit diet as well as in other measures that prove effective in diarrhea. He cites clinical histories to prove that the salt-free diet is effective in diarrhea. If the salt-free diet is employed in diarrhea, it should be carried out along lines similar to those employed in nephrosis. Sweet foods are especially desirable; the sugar replaces the salt to a considerable extent. The fluid intake should consist chiefly of fruit juices and indifferent mineral waters. Discussing the action mechanism of the salt-free diet in diarrhea the author shows that it is readily understandable on the basis of the laws of osmosis.

Septicemia Abscess of Kidney and Perinephric Phlegmon in Newborn Infant D A Giraldes—p 636

**Erythema Nodosum and Pulmonary Tuberculosis**—The Rascovskys report six cases of erythema nodosum in children ranging in age from 4 to 9 years. The condition developed in the course of a febrile attack similar to grip, during which the patients had a cough without any sputum. Four patients had a history of contact with patients who had pulmonary tuberculosis. The clinical examination for pulmonary tuberculosis gave negative results in three cases and positive results in three. The Mantoux test gave strongly positive results in all cases except the third, which became positive during aggravation of

the febrile and pulmonary symptoms. Roentgenograms were taken in the course of the febrile attack during which erythema developed. They showed secondary tuberculous infiltration at the hilus of the lung in three cases, secondary infiltration around the hilus in one case and primary infection in another. One of the patients was apparently in good health, but since the father had pulmonary tuberculosis a roentgenogram was made of the child's thorax, which showed the presence of a typical primary complex of recent development at the upper lobe of the lung. Three years later erythema nodosum developed three months later measles. Roentgenograms made in the course of the disease showed that the primary complex was entirely effaced. Two of the patients in the group developed allergic hypersensitivity and asthma within a year after the erythema disappeared but which improved after desensitization.

**Virus Elementary Bodies in Pemphigus** —Wolfram gives a brief survey over the efforts that have been made to detect an infectious causal agent of pemphigus and thinks that the supposed agent probably belongs to the invisible viruses rather than to the bacteria. At his request a search was made for virus bodies in pemphigus blisters at Gerlach's institute. When this investigation gave positive results, the author decided to study all cases of pemphigus seen in his clinic for the presence of virus bodies. Investigations were made on eight cases of pemphigus and on six cases of dermatitis herpetiformis. Duhning staining with victoria blue and with the primulin method was done in all cases. If the outcome was the same with the two stains, the results were regarded as positive provided the other criteria were fulfilled. The positive results of specimens that were stained according to Paschen's method or with Morosow's silver stain were accepted as valid only if at least one or both of the first two staining methods gave the same results. In all examined cases and in the majority of the examined specimens, granular formations were detected which were in every respect like the virus elementary bodies of the virus infections.

\*Vascular Diseases After Poisoning with Mercury K Fellingner and F Schweitzer —p 269

**Vascular Diseases After Mercury Poisoning** —Fellinger and Schweitzer report the clinical histories of three patients in whom severe vascular impairments developed in connection with mercury poisoning. To be sure it is justifiable to inquire whether the vascular lesions are actually the result of a mercury intoxication or whether their concurrence with mercury poisoning is merely accidental. Although positive proof is lacking, many factors militate for a causal role of the mercury poisoning. In all three cases the vascular lesions developed at a time at which although the early signs of mercury poisoning had disappeared, the chronic manifestations and sequels (dental lesions, tremor and psychic changes) were completely developed. This appearance at a time when late lesions and sequels develop seems to indicate that the vascular changes belong to the other manifestations of mercury poisoning the more so as the chronological connection is similar to that which is observed in lead poisoning, in which vascular impairments are comparatively

frequent. Moreover it appears improbable that, in comparatively young and hitherto entirely healthy persons, vascular lesions should develop with great rapidity, when it is considered that Raynaud's and Buerger's disease generally develop at first insidiously, causing only minor symptoms. These and other considerations make it probable that these vascular lesions and their sequels have a causal connection with the mercury poisoning. It was impossible to make anatomic studies on the vessels of the three patients with mercury poisoning, but the clinical manifestations of the vascular lesions resemble those of the various forms of obliterating endarteritis, however, in their unusually rapid, almost fulminant, course they differ from idiopathic vascular diseases.

Epinephrine Effecting Inhibition of Resorption in Alimentary Alcoholism B Siegmund —p 1842  
\*Therapy of Nontropical Sprue H W Hotz —p 1843

**Pathogenesis of Essential Hypochromic Anemia** —Thiele directs attention to an anemia of the hypochromic type which frequently concurs with achlorhydria or achylia and occasionally with atrophies of the pharyngeal and esophageal mucosa. Moreover, it is often accompanied by koilonychia and by paresthesia, and it develops chiefly in women between the ages of 20 and 40. As regards the etiology of this form of anemia the opinions are still divided, but the role of the stomach has been discussed repeatedly. Those who investigated the problem of postoperative anemias have pointed out that the precipitated evacuation of the stomach plays an important part in the pathogenesis of these anemias. The author noted that in essential hypochromic anemia the gastrointestinal passage is almost regularly excessively accelerated. The evacuation of the stomach and of the upper portion of the small intestine is so rapid that after an hour the jejunum is empty and the chyme is already in the ileum. The author shows that the accelerated gastrointestinal passage of essential hypochromic anemia must be regarded as peculiar to this disease and the question arises whether this accelerated passage leads to disturbances in the resorption. He cites several investigators who are of the opinion that an accelerated passage of the ingesta through the small intestine impairs the resorption. The resorption of iron takes place chiefly in the duodenum and so it may be concluded that only a part of the iron content of the food is utilized during the accelerated transport in patients with essential hypochromic anemia. The author cites animal experiments made by M B Schmidt which demonstrated that hypochromic anemias produced by iron deficiency increase in severity in successive generations. This was explained as resulting from the depleted iron depots in the maternal organism. In this connection the author points out that essential hypochromic anemia often shows familial appearance. Moreover, it has been observed in families in which other members had pernicious anemia, achlorhydria or achylia. Deficiencies in acidity and ferments are often detected in the female forebears of patients with anemia. The author reasons that children from mothers who have an impaired intestinal resorption probably inherit a subnormal iron storage, although they may not develop anemia. It may be assumed that this deficient iron depot is incapable of coping with extraordinary demands such as menstruations and pregnancies and so it is explained why essential hypochromic anemia appears chiefly in women.

**Therapy of Nontropical Sprue** —Hotz says that it is not justified to regard the prognosis of nontropical sprue as entirely unfavorable. He shows that, although complete cure is rare, a suitable therapy will produce in the majority of cases freedom from symptoms. To be sure, since relapses are frequent the patients must remain under the supervision of the physician. Of twenty-two patients who were observed and treated

by the author, four were cured, thirteen were so greatly improved that they were able to resume their work, and five died of complications. The treatment requires much patience on the part of the physician as well as of the patient and it necessitates hospitalization. It consists chiefly in dietetic measures and in the administration of liver extracts. The intake of fats and carbohydrates should be reduced, but proteins, vegetables and fruits should be given in generous amounts. The liver extract must be given in large doses for a long time by parenteral administration. As soon as remission of the anemia is obtained, the liver therapy should be combined with oral and, if necessary, with intravenous administration of iron. With the administration of adrenal cortex extract and of yeast, a treatment which Verzar recommended for nontropical sprue, the author obtained no results which even approximately compared with those obtained by his own dietetic and liver therapy.

 Roentgenologic Appearance of Disappearance of a Cavity K V Pometsov—p 49  
 Roentgenologic Demonstration of Fresh and Old Cavities A Ya Rabinova—p 60  
 Healing of Tuberculous Cavity T N Olenov—p 69

**Tuberculous Lobitis**—According to Zvonnikov, lobitis in the majority of cases is a manifestation of a primary infiltrating flare-up of the tuberculous process. Three factors play a part in the formation of a lobitis: the interlobar septum as the point of origin, local sensitization of the pulmonary tissue and a partial atelectasis accompanying the inflammatory process. Correct topographic diagnosis is arrived at through oblique and frontal roentgenograms. Diagnostic errors are committed principally in the cases of tuberculous lobitis with an acute onset. The differential diagnosis includes nonspecific pneumonia, cancer of the lung and lobar atelectasis. The prognosis of tuberculous lobitis is governed by two contrary tendencies. On the one hand the process tends to remain limited to the lobe for a long time, on the other, it displays an early tendency to break down and form cavities. Spontaneous recovery is possible but is extremely rare. Regressive alterations in favorable cases are those of resorption, scar formation or gradual resorption with disappearance of the interlobar septum. The therapy of lobitis is collapse. Artificial pneumothorax or phrenic exeresis is recommended for the acute cases and thoracoplasty for the old fibrocavernous forms. In the author's material artificial pneumothorax gave a satisfactory clinical effect in 48 per cent of the cases and phrenic exeresis in 21 per cent. The relative effectiveness of the two methods, however, cannot be arrived at from these figures because of the dissimilarity in the gravity of the cases.

 Some Cases of Transplantation After Orell's Method W Risinger—p 152  
 Congenital Pseudarthrosis of the Leg K Stenport—p 181  
 \*Different Types of Tuberculosis of Hip in Children G Odelberg Johnson—p 197

**Plastic Operations in Loss of Thumb**—Koster shows that extreme conservatism is necessary in operations on the thumb. If in spite of this it becomes necessary to amputate a thumb though the metacarpus is preserved and the carpometacarpal joint is mobile, it is advisable to mobilize the metacarpus by phalangization, a fissure being formed between the first and the second metacarpus. The author reports three cases in which this operation was successful. Descriptions are given of some of the numerous forms of plastic operations on the fingers such as finger substitution of Lucksch and the plastic operations on the fingers according to Nicoladoni. These operations, aside from being technically difficult, rarely produce the desired

results, that is, free mobility of the transplanted parts. Phalangization is the easiest operation, it rapidly produces a useful finger and it answers the demands which must be made on a finger substitute: strength, motility and sensitivity.

**Tuberculosis of Hip**—Odelberg-Johnson reports seven cases of tuberculous coxitis in children, illustrating the following types of this disease: (1) coxitis with primary destruction of the acetabulum, (2) coxitis with primary luxation, (3) focus in the neck of the femur with perforation into the joint and (4) sequestration of the capital epiphysis. It is pointed out that in the early stages of tuberculous coxitis weight put on the extremities as well as muscular contracture may contribute to the deformity of the atrophic bony components of the joint and also to the development of bone destruction in adjacent parts of bones. Moreover, "extra-articular pseudarthrosis" usually develops after coxitis in early childhood and this morbid condition often is the final stage of infantile coxitis with primary luxation.

### Ugeskrift for Læger, Copenhagen

100 1367 1396 (Dec 8) 1938

- (Chlamydia in Men I Andresen—p 1367  
 \*Treatment of Retention of Testis with Special Regard to Hormonal Treatment and Indications for It E Guldberg—p 1368  
 \*Some Cases of Apicitis H Rasmussen and T Meyer—p 1375

**Treatment of Retention of Testis with Special Regard to Glandular Therapy and Indications for It**—Guldberg advocates the institution of glandular therapy at the age of 10 in all cases of uncomplicated retention of the testis and in cases complicated with hernia. He says that if the treatment is not effective it will not lessen the chance for successful operative treatment and often considerably improves it. This view, he affirms, is supported by his results in the seven cases reported in which glandular therapy was given, in three instances followed by operative treatment. Cases in which the testis is fixed by stenoses in the inguinal canal, adhesions and so on are considered unsuited for endocrine treatment, they call for operation and later glandular therapy if needed. Glandular therapy is contraindicated in cases of malignant degeneration and ectopia, also in cases with threatening incarceration of the testis, which might increase to a fateful degree on glandular therapy. A complicating hernia may by rapid growth or incarceration indicate early operation regardless of the patient's age. In these cases one must try to avoid such changes in the anatomic conditions as might hinder a later spontaneous descent of the testis or a descent effected by glandular therapy.

**Some Cases of Apicitis**—Eight cases are reported, six in children from 6 to 12 years of age. In seven the diagnosis of apicitis was verified roentgenologically, in one only at necropsy. Rasmussen and Meyer state that the clinical symptoms vary greatly and may be vague or entirely absent and that only a ray examination establishes the presence of a destructive process in the apex. There was paresis of the abducens nerve, together with characteristic pain in three cases in two of which the paresis set in on the thirtieth and forty-sixth day respectively, in one there was double vision from the first day of the otitis. Five patients, including two of those with paresis of the abducens, had increased cell count in the spinal fluid. In three instances pronounced changes in the apex were manifest on the first x-ray examination on the eleventh, eighteenth and twenty-first day respectively of the apicitis. In the other four, marked changes appeared on later examinations. That the apicitis was accompanied by sphenoid sinusitis in five cases points to the advisability of careful examination of the sphenoid sinus in apicitis. In the first fatal case Ramadier's operation failed because there was not enough space between the carotid canal and the promontory to allow access to the apex. Operation on the apex with evacuation was done in four cases on the twelfth to the thirty-eighth day, in two by Ramadier's method. In all four there were soft cells in the apex with granulations or pus. One of these patients died from meningitis after a revision operation. The remaining three patients, two with marked processes in the apex, recovered although only ordinary chiseling was performed, with emptying of the perilabyrinthine cells. The author feels that more definite guides are needed for the treatment of apicitis, also for the time for operation.

## THE PERIODIC HEALTH EXAMINATION AS A METHOD OF CLINICAL INVESTIGATION

REGINALD FITZ, M D

BOSTON

In 1923 I became interested in periodic health examinations and determined, for my own satisfaction, to discover whether or not such examinations were of use. In this paper I shall report certain results of my observations during the last fifteen years, stressing particularly my conviction that the periodic health examination method opens an interesting approach to a certain type of useful clinical investigation.

The beginning of the periodic health examination plan is of considerable historical interest. Lemuel Shattuck<sup>1</sup> of Boston, schoolmaster and visionary, deserves credit for first having promulgated it in this country. In 1850 in his famous report he recommended that individuals be encouraged to have frequent sanitary examinations made of themselves in an effort to promote their health and to prevent disease. For, said he, in the literature on health too much importance is attached to public health and too little to personal health. In order to maintain personal health, the history and condition of each individual's constitution should be studied and the character of the blood that courses in his veins should be ascertained from time to time. "Our persons should be *preserved* and *strengthened* by wise and uniform care and training. We should *cleanse* our persons by daily ablutions properly applied at suitable times and of the right kind and temperature, *strengthen* our persons, physically and intellectually by regular and progressive, not transient and excessive, exercise and labor, and should *refresh* our persons by rest and sleep, at proper times, in right places, by suitable means, and in sufficient quantities." He predicted that if careful personal sanitary examinations were periodically conducted there would be much less of the ravages of cholera, typhus and other epidemics in the community, and less also of isolated "sporadic diseases." Eleven years later Dr. Horace Dobell<sup>2</sup> advocated the same idea in England, and in 1900 Dr. George M. Gould<sup>3</sup> again put in a plea for it in the United States "as a means for adequately and scientifically conducting life." These three pioneers, however, like so many others, were never taken seriously by either physicians or laymen.

In 1913 a group of progressive business men foregathered and concluded that the periodic health examination idea not only was a good one for the client but also might be made a commercial success. At first these business men propagated the idea more effectively among the public than among physicians. But in 1922 the American Medical Association<sup>4</sup> became interested and appointed a committee to outline procedures and devise examination forms for the making of such examinations.

In reviewing the literature on periodic health examinations that has accumulated, one is struck by two peculiarities: the layman, on the whole, apparently can be easily interested in the plan and would like to cooperate in it; the physician, on the other hand, has been lukewarm to it, rather incredulous of its value and so far has not grasped its complete potentialities. This is in large measure due to the fact that individual physicians have but rarely taken the matter seriously.

### THE METHOD OF PERIODIC HEALTH EXAMINATION

The periodic health examination technic is not difficult. It entails no more than a history of the case methodically recorded and a complete physical examination of the patient repeated at intervals as time goes on. It need include as a routine only the simplest laboratory work: a Wassermann test, urinalysis, examination of a blood smear and estimation of the hemoglobin concentration. Occasionally more complicated procedures will be required such as x-ray studies or a determination of the basal metabolic rate. Chiefly the method requires a good system of records and follow-up, reasonable clinical judgment, a great deal of patient listening and, above all, in order to make the patients return from time to time, willingness on the examiner's part to assume a vital interest in the life of the person whom he examines.

In the cases reported here, the histories and physical examinations were uniformly made on a Mayo Clinic<sup>5</sup> history form, and in each instance such laboratory procedures were carried out as seemed indicated at the time of any examination. The patients were followed up in different ways, mainly by personal periodic rechecking at annual intervals or less or by correspondence with patients or their friends, by correspondence with physicians or hospitals, or even through the death notice column of various newspapers. In this manner a considerable volume of material has been assembled from which to construct the life history of a group of persons from the time they were first examined until they died. Thus an effort has been made on a small

scale to develop knowledge regarding the clinical beginnings of a variety of fatal disorders

There is one difficulty about the technic of the periodic physical examination which cannot be overstressed. As judged by my own experience it is well nigh impossible to train oneself to be sufficiently systematic in one's work and to be properly thorough. My own conscience is by no means clear. I can recall at least one rectal cancer that developed under observation without

Fig 1—The apparent disappearance of murmurs in a patient supposed to have rheumatic heart disease

a note as to any initial rectal examination, an ovarian tumor that grew with never a vaginal examination being reported until too late and a neoplasm of the testis which through superficial and hasty examination was thought to be hydrocele. If one wishes to use the periodic health examination as a method of clinical investigation one must be as scientific in its use as in the use of any other research method, one must always be workman-like and painstakingly thorough lest the one important clue to the early manifestations of a disease be unrecognized through carelessness.

#### THE COMMON CAUSES OF DEATH IN THE UNITED STATES

Dublin and Lotka<sup>6</sup> have published interesting tables giving the common causes of death among the policyholders of the Metropolitan Life Insurance Company. In 1935, according to their figures, and they probably are as accurate as any, the ten leading causes of death in the United States were those given in table 1. Statistics such as these are necessarily significant to the periodic health examiner. What can be learned from the manner in which common causes of death develop that may be useful in preventing them or in mitigating their course once they have developed as a form of disease clinically recognizable?

Of heart disease there is little to be said. There were many cases of rheumatic and syphilitic heart disease and a few of congenital heart disease in this series, but the lesions were firmly established and incurable by the time the patients were first observed. In recent years, certainly, much has been accomplished to make the life of the cardiac patient longer and more useful, a good deal is being done, as Sir William Osler so fervently hoped, to jugulate syphilis and thus prevent syphilitic heart disease, but the problem of preventing or curing rheumatic heart disease still faces us. That possibly rheumatic heart disease is at times curable is suggested by the observations of Bland, Jones, and White,<sup>7</sup> who found in a group of 1,000 young persons

with clinical signs of rheumatic heart disease that in the course of time the physical signs characteristic of valvular disease disappeared in eighty-three instances. I have occasionally encountered such cases, always an experience sufficiently impressive to discount some of one's natural pessimism concerning the incurability of rheumatic heart lesions in young persons.

A girl aged 14 years had double mastoiditis in September 1926 followed by an attack of swollen and painful joints. In May 1927 her joints again became painful, and in June, when she was first examined, the blood pressure was 105 systolic, 60 diastolic, there was a blowing systolic murmur at the apex and a low pitched diastolic murmur along the sternum. She was later examined at intervals for several years. At first there was no change in the character of the murmurs, in 1930 all that could be heard was an apical systolic murmur, and after 1933 the heart sounds appeared entirely normal. The last time she was seen was in the fall of 1938, when she appeared the picture of health and had a heart that seemed normal in every way.

What makes certain persons able to recover from heart disease?

**Cancer**—Malignant disease indeed presents a bewildering problem. Table 2 illustrates the manner in which various tumors developed in patients under observation and emphasizes the difficulties entailed in early diagnosis.

To me the impressive feature of watching such cases was the apparent suddenness of onset of important symptoms. More data of this type should be recorded to confirm or refute the impression that cancer often begins its clinical course not insidiously but suddenly and that to recognize cancer early is impossible by present methods because the disease in its early stages produces no recognizable manifestations. If this is true, what is badly needed is a test for cancer analogous to the tuberculin test for tuberculosis and the Wassermann test for syphilis, by which cancer may be recognized.

Fig 2—The development of cardiac hypertrophy, hypertension, peripheral vascular and retinal lesions in polycystic kidney disease

in its preclinical state. Until such a test is developed cancer inevitably must continue to be discovered in most cases when it is already far advanced.

**Accidents**—These are a constant threat. In this series two patients died from having fish bones stuck in their throats. Several found the vicissitudes of life unbearable and succumbed to self-inflicted trauma. One patient was run over, another was shot, a third was killed in an airplane crash. A man with well compensated valvular heart disease suddenly dropped dead

7 Bland P. B., Jones T. D. and White P. D. Disappearance of Physical Signs of Rheumatic Heart Disease. J. A. M. A. 107: 569-573 (Aug. 22) 1936.

from the exertion of attempting to save property from his barn, which had caught on fire. A somewhat older man was driving his motor car during a bad snowstorm when visibility was poor and collided with a railroad train. Were any of these fatalities preventable? They were discouraging because they seemed so unnecessary.

TABLE 1—Ten Leading Causes of Death in the United States in 1935

Diseases	Death Rate per 100 000 (Standardized for Color, Sex, and Age)
1. Diseases of the heart	138.6
2. Cancer	86.8
3. Influenza and pneumonia	67.8
4. Accidents (all forms)	57.5
5. Tuberculosis (all forms)	50.4
6. Chronic nephritis	52.0
7. Cerebral hemorrhage	47.0
8. Diseases of the coronary arteries and angina pectoris	32.4
9. Diabetes mellitus	20.5
10. Appendicitis	11.5

And yet how could they have been forestalled? Even a simple clinical study of a series of fatal accidents with analysis of the patient's previous medical history and of the events leading up to death might throw important light on a public health problem of increasing magnitude.

**Tuberculosis**—This is always a surprising disease. It keeps cropping up unexpectedly. Several years ago Dr. W. G. Smilie and I became interested in the problem of tuberculosis in medical students. A group of supposedly healthy students were tuberculin tested each year during their medical student life. It was surprising to see the proportion of negative reactors who became positive during that interval of time.

Having a positive tuberculin reaction is not the same thing, however, as having clinical tuberculosis. The onset of clinical tuberculosis, at least in certain instances, is strikingly acute.

In 1927 a robust looking young man went away on a vacation. He was in good condition so far as he knew. He played a violent game of tennis one morning and immediately after it began to raise large quantities of bloody sputum. Over the right upper lobe were rales and exaggerated voice and breath sounds. Roentgenograms of the chest showed marked infiltration through both lungs, suggesting an acute bronchopneumonia. The sputum contained tubercle bacilli.

To recognize the reactivation of a latent tuberculosis is a much more difficult matter.

A man aged 34 complained of a sore mouth in June 1933 which had apparently developed from bands on his teeth. Since the soreness persisted, a bit of tissue was removed from the floor of the mouth for microscopic examination. This showed no significant changes. Finally, because the symptoms continued, the sublingual glands were dissected out and proved to be tuberculous. This finding led to a chest film. There was infiltration in both lungs with lesions which appeared discrete and inactive. There was nothing in the past history to suggest when the lesion developed except that as a youngster the patient had been liable to "colds" and that he had been very ill with influenza in 1918. He was advised to take things easily for a few months until his mouth entirely healed up. He gained 20 pounds (9 Kg.) and felt perfectly well. In February 1936, having been in perfect health for a year, he began to complain of a sense of stiffness in his neck and of recurrent attacks of vertigo. Eventually these symptoms proved to be due to a tuberculoma of the left cerebellar hemisphere and to tuberculous meningitis.

When and how did the disease originally commence?

If a positive tuberculin reaction means what it is thought to mean, namely a form of tuberculosis either inactive or active within the body, we shall continue to

see a great deal of tuberculosis for many years to come. In order to combat the disease most intelligently we must continue to improve methods for treating it when it is active. Also we must continue to develop methods for recognizing it in its early stages. For the latter purpose the periodic health examination method should be important. There is a vast literature on tuberculosis and its treatment after the disease has developed, on the other hand there is very little description in carefully studied cases of how it begins. A critical analysis of the mode of onset of the disease in patients studied before as well as after they fall ill would be surprisingly useful in the antituberculosis campaign.

**The Cardiorenal Group Including Chronic Nephritis, Cerebral Hemorrhage and Diseases of the Coronary Arteries and Angina Pectoris**—Vascular disease in one of its various forms is by all odds the most common disease encountered in practice. Yet of its origin and early diagnosis little or nothing is known.

A man aged 48 was interested in periodic health examinations because he happened to occupy an unusually responsible position in the business world. In October 1924 he felt well. He was slightly overweight. His blood pressure was 150 systolic, 80 diastolic. The urine was normal. The heart was normal in shape as judged by ordinary physical and x-ray examinations. There were no murmurs. The eyegrounds showed nothing remarkable. The peripheral vessels were palpable and slightly thickened but were not sclerosed or tortuous.

In October 1925 he still felt well. No appreciable change in his physical condition had taken place. The blood pressure level was the same. The peripheral and retinal vessels were

unchanged. The size and shape of the heart were unchanged, and the heart sounds continued to be normal. He died two months later of a sudden coronary thrombosis.

The widow of a patient with a similar history asked me how it is that a vigorous man in apparently splendid health can have such a frail hold on life. I wish I knew the answer.

I have made a conscientious effort to pick out even one case in which I could truthfully say that arterio-sclerosis had developed under observation. I must

confess that the onset of vascular disease has seemed so insidious that it has been beyond my power to recognize it

My nearest approach to watching the development of arteriosclerosis and hypertension was in a patient with polycystic kidney disease whose course was followed for nine years. My observations are of some interest, though I do not feel sure that they throw any light on how or why arterial degeneration develops

Fig 3—The growth of the kidneys in polycystic kidney disease

As can be seen (fig 2), vascular changes, hypertension, cardiac hypertrophy and retinal changes developed during the progress of a notably chronic renal insufficiency. Was the renal disease primarily responsible for the whole picture or had the patient two independent lesions, one in the kidney and the other in the vascular system?

There are several questions of this kind that can be answered only by following individual patients through all stages of vascular disease from before its beginning until its end, and this method of approach is obtainable only through the periodic health examination method. I venture to predict that if as small a group as 100 individuals were carefully studied from birth until death by the periodic health examination method, the information obtained from such a clinical investigation would throw considerable light on the early manifestations of several chronic diseases.

**Diabetes**—Joslin<sup>8</sup> says that the date of onset of diabetes is usually indefinite. Then he adds "It will be worth while to endeavor to learn more accurately the type of onset of diabetes. It will furnish assistance in a search for the etiology and will raise queries in the minds of the pathologists, it should indicate the character of the methods which must be adopted for prevention, it may be of value in classification and prognosis."

I can recall having seen four patients under supervision in whom diabetes developed. As in the case of cancer, in each instance I have been struck not by the indefiniteness with which the disease began but rather with its suddenness.

A man aged 30 was treated at the Peter Bent Brigham Hospital in 1921 for lobar pneumonia. During his hospital stay three samples of urine were examined, one of which contained a trace of sugar, the other two being sugar free. Six weeks later he reentered the hospital. After leaving he had felt splendid, gaining 16 pounds (7.3 Kg) and recovering all his strength. Suddenly he developed a ravenous appetite and a marked thirst and he began to lose weight. He was then discovered to have diabetes.

A man aged 47, 6 feet (183 cm) tall, weighed 227 pounds (103 Kg) in July 1930. His urine was normal. The blood sugar concentration after a hearty noon meal was 0.12 per cent.

In April 1932 his weight was unchanged. He was advised to lose weight lest by remaining fat he run the risk of having diabetes develop. He followed this advice for a time, so that in June 1933 he weighed 206 pounds (93.4 Kg). The urine was sugar free and the blood concentration was 0.11 per cent. In October 1935 he returned with 6 per cent sugar in his urine and a blood sugar concentration of 0.29 per cent. A few weeks previously he had suddenly noticed a little urgency of urination, nocturia and itching of the glans penis.

A man aged 45 was studied at the Robert Dawson Evans Memorial in October 1933. His blood sugar concentration was normal in several tests and the urine was sugar free. In May 1937 he suddenly developed a ravenous appetite, began to drink a great deal of water each day and pass large quantities of urine. Now the blood sugar concentration was 0.28 per cent and the urine contained 2.2 per cent of sugar.

A woman aged 60 entered the Robert Dawson Evans Memorial in July 1936. Because she had myxedema with a basal metabolic rate of -27 per cent she was given a sugar tolerance test. This was not abnormal. She was given thyroid and in January 1937 with a basal metabolic rate of -6 per cent the sugar tolerance test was repeated and again was found normal. In January 1938 her basal metabolic rate was +10 per cent, the blood sugar concentration was 0.12 per cent and the urine was sugar free. Last July during the berrying season she suddenly noticed one day when it was warm that she could not seem to get enough to drink. The thirst persisted. Soon she found that she was becoming unusually hungry and she noticed that she was losing weight. She reentered the hospital in September with a basal metabolic rate of -8 per cent, now with 1.5 per cent of sugar in the urine and with a blood sugar concentration of 0.49 per cent.

In each of these four cases the diabetes apparently developed suddenly. It would be extremely interesting to have reported the mode of onset of diabetes in a large group of cases in which the disorder had developed under observation. As Joslin suggests, a clinical investigation of this character might well be of assistance in discovering the etiology of diabetes and might well indicate new methods for preventing the disease.

Fig 4—The pathologic changes of polycystic renal disease gross appearance of kidneys combined weight 7500 Gm

and for learning more of its life history. The periodic health examination offers a good method for such an investigation. Why will not some physician undertake it?

**Appendicitis**—That appendicitis is an important cause of death in the United States is a great pity. Considering how much is known of the disease, of its early diagnosis and of its treatment, it seems peculiar that so many people each year should die as a result of it. One

<sup>8</sup> Joslin E P. The Treatment of Diabetes Mellitus ed 6 Philadelphia Lea & Febiger 1937

case looms large in my mind, making me raise the question as to whether prophylactic appendectomy does not deserve a certain amount of consideration in selected cases

A woman aged 71 wished to live comfortably as long as she could and felt that periodic health examinations might be of some use to her for this purpose In 1927, when she was

Fig 5—Section reduced from a photomicrograph under medium power showing portion of pyramid No glomeruli present The collecting tubules are dilated and filled with polymorphonuclear leukocytes There is an acute inflammatory infiltration of the interstitial substance (Courtesy of Dr Kenneth Mallory Boston City Hospital)

first examined, she had a considerable degree of vascular disease with tension of 190 systolic and 80 diastolic The urine was normal The renal function was normal The eyegrounds showed evidence of vascular disease but no hemorrhages or exudates In 1928, 1929 and 1930 she appeared to show no signs of wear and tear Nothing about her general condition had changed except that she had lost a little weight in an effort to obey the medical advice given her May 5, 1930, she seemed as well as ever Two months later an attack of pain developed in the right lower quadrant with fever, nausea and vomiting She did nothing about all this for three days, and then it was too late She had a ruptured appendix with pelvic peritonitis and a terminal acute nephritis

Could she have enjoyed life longer and more effectively had her appendix been removed before it had become acutely inflamed?

**Miscellaneous Diseases**—Fifteen years' experience with the periodic health examination method is too short a time in which to draw any sweeping conclusions as to its ultimate usefulness During this period, however, I have seen isolated examples of the beginnings of several other diseases of obscure etiology in addition to the cases cited I believe that data obtained through the use of this method are bound to yield important results as literature on the clinical beginnings of such diseases accumulate For instance, in this series there were three patients with dementia praecox who were observed first as well persons, then as persons who appeared peculiar but harmless and finally as persons who needed institutional care A detailed report of a large series of such cases similarly observed would be helpful Two cases of multiple sclerosis were followed from the time when even expert neurologists were unable to make any diagnosis until at last the classic clinical features of the disease developed Certainly further knowledge is needed of what multiple sclerosis is and how it commences One patient was regarded as perfectly healthy until she had what appeared to be a trivial acute infection of unknown etiology From

this beginning a progressive organic disease of the spinal cord steadily developed which the pathologist was unable satisfactorily to classify In one patient myelogenous leukemia seemingly developed after she had been considered for several years to have polycythemia vera, and in another acute fulminating lymphatic leukemia developed under observation Exophthalmic goiter, gout, duodenal ulcer, gallstone disease, renal stones and fibroid tumors of the uterus have become apparent in patients without physical signs of such abnormalities when they were first examined On the whole, it is almost certain from this short experience that, if any physician will but stop to realize that man is naturally a long lived animal with peculiar liabilities to disease, if he will be patient, if he will be methodical and accurate in his description of the phenomena he observes, he has abundant opportunity at hand to inquire into the beginnings of a variety of clinical conditions by the periodic health examination method and thus to add significantly to clinical knowledge

HUMAN RELATIONS AND HEALTH

Finally, the periodic health examination method affords a technic for studying the very baffling problem of human relations and health There can be no doubt that factors such as fear, worry, happiness and unhappiness influence the way people feel By studying persons periodically and recording how their bodies react to external stimuli such as poverty, prosperity, contentment and discontentment, data may be obtained which can be expressed in measurable terms and thus be susceptible of analysis

A patient had a gastro enterostomy in 1920 The possible effect of social and economic misfortunes in relation to subsequent hemorrhage is shown graphically Whatever may be the

Fig 6—Human relations and health The possible relation of unhappiness and poverty to intestinal hemorrhage

underlying pathologic condition, it is a reasonable conclusion that no treatment for this patient will be successful which does not include in its program correction of aggravation, discouragement and financial worry as well as correction of any mechanical fault in the digestive tract

CONCLUSION

On the whole, the periodic health examination method should be regarded seriously as an important tool for clinical investigation In the light of present knowl-

edge so little is known of the mode of origin of many diseases that to expect the periodic health examination to be very useful in preventive medicine is unsound. The method, however, affords a means for studying the beginnings of a variety of disorders. Too little emphasis has been placed on the fascination of investigating how chronic disease begins. Accurate descriptions of the beginnings of all chronic disease are needed before rational preventive measures can be established.

To use the method of periodic health examination to full advantage requires the critical observation of a large group of persons over a long period of time. No one physician in his lifetime can expect to add more than a fragment of knowledge to all that can be obtained by the use of this method. Every physician, however, has an opportunity, as Sir William Osler said, to observe, record, tabulate, communicate. In this manner he has the chance to add bits of knowledge to the general fund of what little is known of the clinical beginnings of the common causes of death. The importance of the periodic health examination as a method of clinical investigation should be recognized. It should be utilized more generally.

78 East Concord Street

## THE TOXIC MANIFESTATIONS OF THE THIOCYANATES

MAURICE H WALD, MD

HOWARD A LINDBERG, MD

AND

M HERBERT BARKER, MD

CHICAGO

The increasing use of the thiocyanates in the treatment of hypertension suggests the need of a statement relative to the toxicity of this drug. Heretofore the only reports on this phase of therapy have been sporadic accounts of severe intoxication. Under such circumstances it may be understood that a great disparity of opinion relative to the advisability of using the thiocyanates therapeutically has arisen. This was justified in the face of the lack of satisfactory guides to its proper dosage. After ten years' experience with cyanate therapy, carefully controlled by determinations of the blood content of the drug, we feel prepared to offer a critical analysis of the literature on the subject of its toxicity and to make some suggestions for the clinical guidance to the toxicology and therapeutics of this salt.

It is essential at the outset of this communication to reemphasize the importance of the relationship between thiocyanate toxicity and the actual quantity of the electrolyte present in the blood of the patient. The drug is stored in the body, there being widely distributed in the body fluids<sup>1</sup> and tissues, and its toxic action is cumulative (table 1). The content of the thiocyanate in the blood is an index of the thiocyanate content of the tissues, and this depends on the intake and the rate of excretion of the drug through the kidneys. The rate of excretion of thiocyanates from the body is extremely variable. The only correlation

that we have seen between cyanate clearance and urea clearance is a rather general tendency of the former to be depressed when the latter is quite low. However, patients with normal or elevated urea clearance may also have a low thiocyanate clearance (table 2).

Since it has also been shown that the optimum "safe" level at which the blood cyanate content may be maintained seems to be between 8 and 14 mg (the level at which the hypotensive effect of the drug is fully effective), determination of blood cyanate levels constitutes the present safest guide to dosage. In the light of this information we are able to divide the manifestations of thiocyanate toxicity into two groups: first, those toxic manifestations observed in patients whose blood thiocyanate content is within "safe" limits, though therapeutically effective, for example between 8 and 14 mg per hundred cubic centimeters of blood; second, those toxic manifestations observed in patients whose blood thiocyanate content exceeds these limits, namely between 15 and 20 mg per hundred cubic centimeters of blood or higher. This distinction is of the utmost importance if a true evaluation of thiocyanate therapy of hypertension is to be achieved. A careful review of the literature on this subject has disclosed no instance in which blood determinations were made with a view to controlling dosage. The maintenance dosage in our experience ranges from 0.3 Gm (5 grains) a week to as much as 1 Gm (15 grains) a day, depending on the patient's rate of excretion of the drug at a particular time. Fluctuations in the dosage are seen frequently in the course of therapy in many cases. It is apparent, then, that a statement by an author of the dosage of thiocyanate administered to any one patient cannot be accepted as a guide to therapy or as a criterion of the possible presence of saturation.<sup>2</sup>

In reviewing the reports in the literature we cannot avoid an inclination to group the toxic manifestations which the authors present in terms of our own experience. The tabular review of the literature has been subdivided into three groups according to our interpretation of the toxic phenomena reported. Those symptoms listed in the "mild" category are those which we feel secure in stating were present with blood thiocyanate levels within a "safe" range. Interpretation of those symptoms which are listed in the last column in table 3 as "severe" all fall into a second group associated with very high blood thiocyanate levels. The middle column represents symptoms which might appear in either grouping.

The most common manifestations of cyanate toxicity in the first group are sensations of weakness and fatigue. These are such frequent complaints during the early weeks of cyanate therapy (occurring in 75 per cent of the cases) that we have come to look on them as hardly toxic states. That they should be classed as such is borne out by the occasional patient in whom fatigue and marked weakness are constant complaints during the administration of cyanate, and they are relieved only by discontinuance of the drug. In most cases these symptoms disappear spontaneously from the second to the sixth week of therapy. Some of the fatigue of which the patients complain is not always due to the thiocyanate itself but seems to be due to the hypotensive effect of the drug. It is well

2 As a guide to those interested in the use of this preparation it has been our usual routine to administer two doses of 5 grains (0.3 Gm) a day for three days followed by a blood cyanate determination for patients being observed in the hospital while for those observed only in office or clinic ten doses for a week are prescribed and a blood thiocyanate determination done on the eighth day. Reprints setting forth the simple technique of blood thiocyanate determinations may be had on request.

known that the hypertensive patient whose blood pressure is reduced by any means whatever often complains of marked fatigue and lethargy, as the blood pressure rises toward its former level the patient again feels especially well.

This common symptom of fatigue is not a serious toxic manifestation, and it appears with blood thiocyanate concentrations of less than 8 mg per hundred

TABLE 1—Distribution of the Thiocyanate Ion in the Body Tissue\*

		0.165†	0.272†						

\* Figures for blood thiocyanate content are in milligrams per hundred cubic centimeters of the ion in the blood serum. Figures for the various tissues are in milligrams per gram of the washed whole tissue and represent the average of two or more determinations of separate samples of tissue.

† Values derived from dehydrated and defatted specimens; these are the actual figures obtained on single analysis of the organs.

cubic centimeters. Taubmann and Heilborn<sup>3</sup> found that muscles of guinea pigs treated with thiocyanates showed a greater tendency to fatigue on electrical stimulation than did muscles of normal animals.

Aching and even cramping in the muscles of the calf are common complaints associated with this transitory period of fatigue. As to the cause of the actual cramping in the extremities, it is suggested that this might be on the basis of a reduced circulation, as evidenced by two of our carefully studied cases presenting known peripheral arteriosclerosis, in which pain, cramps and numbness developed repeatedly in the extremities when the blood pressure fell below 160 mm of mercury. These cramps developed with the blood cyanate below critical levels and disappeared as soon as the blood pressure reached 180 mm of mercury.

It will be noted in table 3 that several authors have written on the increased nervousness and irritability associated with the initiation of a cyanate regimen. McNeill,<sup>4</sup> Ayman<sup>5</sup> and Paul,<sup>6</sup> on the contrary, have reported on the supposed sedative action of thiocyanate and several have recorded good results in the treatment of neurasthenia and neurosis. We appreciate the fact that it is difficult to evaluate symptomatic relief of hypertensive states, but it is our feeling that patients do sleep better and are less irritable on treatment. They often report that they feel calm and quiet rather than that they have a feeling of constant drive and anxiety. Many patients feel actually sleepy while taking cyanates. This is often associated with the fatigue state previously mentioned. These conditions are noted even though there is no immediate drop in blood pressure. Nichols<sup>7</sup> also commented that there was a marked relief of nervous symptoms, but he did not believe that this was a true sedative action.

Toxic dermatitis, about which much has been written, has been encountered only six times in our series of patients with controlled blood cyanate levels. This has

taken the form of a maculopapular itching, scaling eruption which is poorly defined, appearing usually on the flexor surfaces of the wrists and forearms or on the lower third of the leg. Occasionally the rash is seen on the face, around the corners of the eyes and lips or over the scapular region. We have never found this to be of serious consequence, it causes little discomfort to the patient and has disappeared on withdrawal of the drug. In most cases we have been able to resume the drug after the dermatitis has disappeared, and there has been no recurrence of the rash. On one occasion the rash did appear the second time but it did not recur on subsequent administration. Only one patient has shown a dermatitis which has recurred on the third attempt at renewal of the drug. Although recognizing that dermatitis is customarily one of the toxicoses resulting from overdosage, we are inclined to classify it in the mild group. The reports in the literature describe severe exfoliating forms of dermatitis with fever, edema of the face and marked general symptoms of intoxication. This may be the result of excessive dosage, but we have not encountered any such severe reaction.

The goiter which occasionally appears seems to correspond to the thyroid enlargement observed by Chesney, Clausen and Webster<sup>8</sup> in rabbits fed a diet of cabbage. Clinically it appears as a benign enlargement of the gland, usually diffuse, with normal or slightly lowered metabolic rate. In one case which was of nodular form there appeared to be a rapid enlargement of a small adenoma which had been present for many years. We have had no opportunity to study these glands pathologically. Enlargement of the thyroid has appeared only after long continued administration of cyanate and with blood values constantly in the lower brackets, and it decreases with feeding of thyroid.

TABLE 2—The Wide Individual Variation in Renal Thiocyanate Clearance, the Lack of Relationship Between Blood Thiocyanate Level and Thiocyanate Clearance and the Marked Difference Existing Between Thiocyanate and Renal Urea Clearance\*

Case	Sex	Age	Type of Case	Urea Clearance, per Cent	Thiocyanate Clearance, Cc per Minute	Thiocyanate Blood Level, Mg per Cent
1	♂	35	Normal	55	3.50	5.70
2	♀	35	Normal	77	1.9	3.80
3	♂	50	Superhypertension	108	0.62	4.70
4	♀	68	Hypertension cardiac decompensation	44	0.32	5.20
5	♂	50	Chronic nephritis advanced	31	0.31	17.1
6	♂	31	Chronic nephritis advanced	5.5	0.62	11.4
7	♂	50	Hypertension	72	0.32	16.2

\* It will be noted however that although a high urea clearance may be accompanied by a low thiocyanate clearance, the latter is consistently low when the urea clearance is low.

The degree of severity of the various gastrointestinal disturbances may well be an index of the height of serum thiocyanate. Mild gastrointestinal complaints do occur, however, with the usual therapeutic levels. These usually consist of pyrosis, abdominal discomfort, anorexia, nausea and, rarely, vomiting. Above the safe blood level, gastrointestinal disturbances consisting mainly of nausea and vomiting are among the first signs of thiocyanate toxicity. Severe diarrhea, much

abdominal pain and cramping may occur independently or as part of a general extreme toxic state. However, we have seen this only twice in ten years. In normal dogs fed toxic doses of the drug over a comparatively long period there always develops severe bloody diarrhea with associated dehydration.

It is well to point out at this time that some hypertensive persons display rather marked gastrointestinal symptoms, as already described, as part of the hypertensive syndrome, which go away with reduction of the blood pressure. These are to be distinguished from

The dogs in our experimental series, slowly intoxicated over a long period of time, showed first loss of weight progressing to marked emaciation, secondly, anorexia and diarrhea of a bloody type developed with marked signs of dehydration. Later spasticity of the hind legs developed, associated with marked weakness. The dogs that did not die from marked inanition developed severe generalized convulsions with marked opisthotonos and died in twenty-four hours. Blood studies that were made during this period showed a severe depression of certain of the blood elements

thiocyanate toxicity most conveniently by determinations of the cyanate in the blood. If serum thiocyanate is within safe limits, we believe that one need have no cause to fear the presence of poisoning.

The work of Nichols<sup>7</sup> with animals intoxicated with thiocyanates stands as the most complete exposition on this subject to date. Using guinea pigs and dogs, and administering various dosages by oral and parenteral routes, he noted sluggishness, diarrhea, anal hemorrhage, marked loss of weight, spinal irritation, spasticity of the hind legs, general rigidity, convulsions, coma and death. The speed of the course of events roughly paralleled the size of the dose. Taubmann and Heilborn<sup>8</sup> noted anorexia, weakness, spastic paralysis and convulsions in their experimental animals.

These, which are to be reported elsewhere, further attest the toxic origin of the syndrome associated with the maintenance of excessive blood levels of this substance.

In the white rat, a single lethal dose injected subcutaneously produces the irritative phenomena with death in a few hours. Chronic poisoning resembles that observed in the dog. The diuresis that Nichols observed in rabbits has not been noted by us in animals but it is of interest because of the occasional diuresis that we have observed in human beings.

Healy's<sup>9</sup> observations on toxicity in rabbits were similar, and he correlated them with what he observed clinically. In addition, he reported pigmentation of the

9 Healy J C New England M J 205 581 (Sept 17) 1931

skin and felt, because of the asthenia and hypotension in the syndrome of intoxication with this drug, that "hypo adrena" resembling Addison's disease must be an important factor in its production. One of his rabbits, dead of thiocyanate poisoning, had large soft adrenal glands which gave a strongly positive reaction with ferric chloride when the cut surfaces were tested for the content of thiocyanate. In an attempt to repeat this work on dogs, however, we have been unable to confirm Healy's observations on rabbits. Grossly, the adrenal glands of several dogs appeared normal. There were no chemical changes of the blood which are ordinarily associated with hypoadrenia. Adrenal tissue analyzed for thiocyanate content showed no qualitative changes that were markedly different from any other tissue. Microscopically, so far as we could ascertain, there were no abnormal structural changes.

The signs of toxicity which we shall place in the second group are those which, in our experience, have been seen only in the presence of high blood thiocyanate levels. Those toxic manifestations enumerated in the first group may, of course, appear in this group as well. Vascular collapse may or may not be associated with one or more of the other major toxic reactions. Cerebral thromboses, as reported by Barker,<sup>10</sup> although next in importance, are probably not primary toxic effects but are secondary to the severe vascular insufficiency resulting from a sudden and marked depression of arterial tension.

The cerebral manifestations seen following the use of potassium thiocyanate seem to be truly toxic. These appear as a rule when the level has reached 20 mg or more per hundred cubic centimeters of blood. They are very important signs and should be watched for in all cases in which cyanate is given. The earliest sign is that of slurring speech associated with word aphasia. The patients very often do not realize that they have this difficulty and it is first noted by some member of the family. They have no other sign of toxicity although the blood thiocyanate level has always been found to be high. Later marked confusion develops and even delirium.

This type of toxic manifestation should not be confused with the cerebral symptoms that might develop in the advanced senile arteriosclerotic patient as a result of hypotension and vascular insufficiency. Among our cases is that of a Negro aged 75 years, with severe generalized arteriosclerosis and marked evidence of cerebral arteriosclerosis, including typical psychic changes. A superimposed confusional state has repeatedly developed during periods of thiocyanate therapy for a severe hypertension. This occurred in spite of the fact that the blood cyanate level did not exceed 12 mg per hundred cubic centimeters and no blood pressure reduction was obtained.

In the whole subject of the toxicology of the thiocyanates there is perhaps a no more confused chapter than that dealing with the relationship between cardiac pain and cyanate poisoning. In addition, the importance of the related incidence of angina pectoris and hypertension must not be overlooked, since our clinical material and that of most other writers on the subject are drawn almost exclusively from the ranks of patients suffering from hypertension. In the series of 3,000 patients with cardiac disorders published by White and Jones<sup>11</sup> angina pectoris was present in 11.8 per cent,

and 33.1 per cent of those patients had complicated or uncomplicated hypertension. Palmer,<sup>12</sup> Palmer, Silver and White<sup>13</sup> and Palmer and Sprague<sup>14</sup> have pointed out the apparent relationship existing between cardiac pain and the administration of the thiocyanates in the therapy of hypertension. They expressed the opinion that the thiocyanates increased the frequency of anginal attacks in patients who had previously experienced such attacks and that in others the onset of angina was initiated by the administration of this drug.

In the hope of lending some clarity to this phase of cyanate toxicology, we present herewith an analysis of the records of forty-seven unselected hypertensive patients who have been observed in our outpatient clinic over relatively long periods. We have considered all instances of precordial pain or pain in the left side of the chest, with or without radiation, as cardiac in origin. In none of these cases have other pathologic changes been demonstrated that might account for this pain. For convenience in this discussion we have grouped our patients with regard to the presence or absence of cardiac pain. Group 1 includes all patients who gave a

TABLE 4—Therapeutic Responses to Thiocyanate Therapy and to Other Treatment\*

	Thiocyanate Therapy		Other Treatment		Totals	
	Num ber	Per Cent	Num ber	Per Cent	Num ber	Per Cent
No history of previous pain (groups 1 and 3)	24	100	7	100	31	100

Pain unaffected	2	18.2	1	20	3	18.75

\* All cases in which thiocyanate was given at any time are included whether or not the level of blood thiocyanate was considered within the therapeutically (as regards blood pressure) effective range. In no case listed was blood thiocyanate ever displayed in the toxic range.

clearly negative history of cardiac pain and in whom pain never developed while under our observation. The total number of cases in this group was twenty-seven (57.4 per cent). Group 2, totaling sixteen patients (34.1 per cent), includes those who gave a clearly positive history of pain before coming under our supervision. Group 3 constitutes patients who gave a clearly negative history of cardiac pain but in whom pain developed while under our care, of these there were four cases (8.5 per cent).

Table 4 presents a brief summary of the therapeutic responses of this group of forty-seven patients. The only comment that we wish to make on this group of patients, which we consider representative of the entire series of patients we have observed, is relative to the work of Palmer and his associates. Our experience seems to indicate that no patient who previously experienced angina suffered a greater degree of angina during administration of thiocyanate. While it is true that the administration of cyanate was associated with the onset of angina, the percentage of patients thus affected has been no greater than in the group treated by other means. Notwithstanding this fact, we are certain that

in a few cases in the last group the angina has developed as a direct result of the hypotensive effect of the drug. The patients who have been studied carefully from the electrocardiographic standpoint and who have had serial tracings made at various times before, during and after thiocyanate therapy have shown no alterations in the original configuration as a result of the therapy.

From our observations on animals and from the well documented reports in the literature on both animals and man, we do not question that coma, convulsions and death do occur as a result of thiocyanate poisoning, although we have not observed these occurrences in human beings. The mechanism of death is not known. Two possibilities seem logical: first, that ischemia of the central nervous system with subsequent thrombosis or vascular collapse may be responsible for the chain of events that follows, which may end fatally; second, that there may exist an acute poisoning of the cells of the brain and cord.

therapy. Today, after from five to ten years of constant and vigorous treatment with satisfactory blood pressure readings, they present a picture of anemia, emaciation and muscular wasting. They are constantly fatigued and have little ambition. As we have pointed out, all these things are observed in experimental animals that have been deliberately poisoned with thiocyanate over long periods of time. Similar degenerative features are also characteristic of severe progressive hypertensive vascular disease of many years' duration. This is particularly true in those who survive a vascular accident and live for years with a substantially lowered blood pressure. It is, then, possible that this picture is a manifestation of the progress of the vascular disease in a patient who many years earlier might have died of heart failure or a cerebral or coronary accident. Although the blood pressure is held in sufficient abeyance to prevent the acute catastrophe, we are witnessing the ultimate complete bodily deterioration secondary to the continued existence of

TABLE 5—Analysis of Deaths Recorded in Table 3, Reported to Be Result of Thiocyanate Poisoning

Author	Dosage	Clinical Course	Comment
Lesser (1898) cited by Nichols <sup>7</sup>	Unknown	Suicidal attempt death in 10 hours no clinical course reported	Necropsy Corrosion and hemorrhage of gastric mucosa
Robert (1906) cited by Nichols <sup>7</sup>	0.3 Gm	Convulsions	Doubtful case
Vintilescu and Popesco (1916), cited by Nichols <sup>7</sup>	100 Gm ??	Delirium convulsions anuria cold sweats unconsciousness extensor rigidity of spine and neck	Necropsy Negative except for presence of poison in tissues
Saleeby	15 grains t i d	Severe pruritic exanthem acute respiratory infection	Coronary and mesenteric thrombosis
Healy	15 grains t i d (1 week) b i d (4 days)	Hypotension associated with weakness which progressed to delirium vasomotor collapse and coma in spite of discontinuation of treatment after 11 days	Death in coma 3½ weeks after beginning treatment
Healy	15 grains t i d (1 week) b i d (3 days)	Progressive weakness hypotension semi coma vasomotor failure coma	Death after 10 days treatment and 1 month after starting treatment
Goldring and Chasis	9.77 Gm (total in 15 days)	Nausea delirium hallucinations motor restlessness nystagmus, convulsions disorientation anuria coma (blood pressure remained high) death 66 hours after discontinuation of treatment	Necropsy Pulmonary congestion pericardial effusion inactive mitral stenosis subendocardial hemorrhages atheroma and ulceration of abdominal aorta nephrosclerosis and profound renal arteriolar sclerosis cerebral edema
Goldring and Chasis	14.49 Gm (total in 18 days)	Same as reported above	Death 6 days after discontinuation of treatment

Analysis of the eight deaths reported in the literature (table 5), which are shown in the right hand column of table 3, shows that one patient died ten hours after the ingestion of an unknown quantity of thiocyanate, another died forty hours after entering the hospital following a suicidal attempt by ingestion of a large quantity of a thiocyanate salt. A third is reported to have died twenty-eight hours after taking 0.3 Gm by mouth. The possibility of this death being due to cyanate poisoning is remote. In the case reported by Saleeby,<sup>16</sup> death resulted from multiple arterial thrombosis, which might have been due to the marked hypotensive effect produced by severe poisoning, although no blood pressure studies were reported in the protocol. The remaining four deaths reported all agree in the antecedent clinical course with that described for experimental animals poisoned with thiocyanates. It appears thus far that in six of these eight deaths reported there is sufficient evidence on which to base an opinion of cyanate poisoning.

The possibility of inducing chronic poisoning by the continued use of thiocyanate over a period of years is an important question. Several elderly patients with severe grades of progressive vascular disease with hypertension, who were at first plethoric and obese and had good muscular development, were placed on cyanate

the basic vascular breakdown. Younger patients with a more elastic type of hypertension and less primary degenerative disease do not seem to show this same effect.

#### COMMENTS

We have made an attempt to present a summary of the toxicology of the inorganic thiocyanates now being more widely used in the treatment of hypertension. That thiocyanates are toxic and, indeed, that their beneficial action in cases of hypertension depends in part on their peculiar toxicology, are extremely important facts of which to be fully aware. We have tried to differentiate those toxic signs and symptoms which might occur normally in the hypertensive person from those which occur directly as a result of cyanate intoxication. We have analyzed the literature for the purpose of interpreting toxic manifestations and even deaths due to thiocyanate poisoning.

We hope that our interpretation may serve as a warning of the dangerous possibilities as well as a useful guide to those using this drug. Most important of all is the interpretation of symptoms as they appear in the light of the level of the blood cyanates. Without blood cyanate-determinations, this drug should not be used.

303 East Chicago Avenue

THE FATAL IONIC MANIFESTATIONS  
OF THE THIOCYANATES

CURTIS F. GARVIN, M.D.

CLEVELAND

The purpose of this report is to draw attention to the fatal toxic manifestations of the thiocyanates.

Ever since the first pharmacologic investigation of the thiocyanates in 1857 by Claude Bernard<sup>1</sup> there have been numerous references to the toxic properties of this drug. However, the observations of Pauli<sup>2</sup> in 1903 that thiocyanates were effective in reducing high blood pressure caused the use of the drug to gain favor. Untoward symptoms occurred so frequently, however, that the drug fell into disrepute until it was reintroduced in the treatment of hypertension by Westphal<sup>3</sup> in 1925. Since that time some investigators have felt that the thiocyanates were valuable drugs,<sup>4</sup> others have felt that they were not only useless but dangerous.

The published work of others and personal observations would indicate that in many instances the continued administration of thiocyanates leads to lowering of the blood pressure. There is a strong impression, however, that this is a secondary consequence of the toxic effects.

At all events there is no doubt that the drug may cause untoward results. Some patients show phenomena analogous to iodism: i.e. coryza, cutaneous eruptions and even exfoliative dermatitis. The usual effect, however, is vertigo and uncomfortable weakness of the arms and legs. In a lesser number of instances mental symptoms develop, in fact, the thiocyanates may cause a toxic psychosis similar to bromide mania with disorientation, hallucinations, mania and ideas of persecution. Finally convulsions, coma and death may intervene. Accordingly to date the Council on Pharmacy and Chemistry<sup>5</sup> has advised against the use of thiocyanates. It has pointed out that the evidence for their value is far from conclusive and has stated the contraindications to their use.

The toxic effects in animals were reinvestigated in 1933 by Jahr,<sup>6</sup> who found that death may occur suddenly but that usually the effects develop gradually with vomiting, diarrhea and emaciation among the first signs. The animals then show weakness, unsteadiness, tremors, inability to gain an upright position after being placed on the side or back, general tonic and clonic convulsions, coma and death.

The minimum lethal dose of sodium thiocyanate varies with different animals but is usually stated to be about 500 mg per kilogram of body weight. Nichols,<sup>8</sup> working with guinea pigs, found the lethal dose to range between 200 and 400 mg per kilogram. In the same ratio, the minimum lethal dose of sodium thiocyanate

for a medium sized man (weighing 70 Kg, or 154 pounds) would be from 15 to 30 Gm (from one-half to 1 ounce).

Search of the literature reveals seven human fatalities due to thiocyanates, in three instances the drug was taken with suicidal intent and in four instances it was administered for therapeutic purposes.

Lesser<sup>9</sup> reported the case of a magician aged 58 who used thiocyanate to convert iron-containing water into "red wine." With suicidal intent he consumed an unknown quantity of the salt dissolved in beer. He died in about ten hours. Autopsy showed corrosions and hemorrhages of the gastric mucosa, and traces of potassium thiocyanate were demonstrated in many of the viscera.

Kobert<sup>10</sup> described the case of a woman who, after taking ammonium thiocyanate 5 grains (0.3 Gm), had convulsions and died in twenty-eight hours. The amount of the drug seems entirely insufficient to produce any material effects. However, perhaps the statement of the amount taken was erroneous.

Vintilescu and Popesco<sup>11</sup> have recorded the case of a man aged 27 who after the ingestion of 100 Gm of ammonium thiocyanate had a toxic psychosis with extreme cerebral agitation, delirium, occasional convulsions and finally death. Autopsy was negative except that numerous organs gave strong reactions for the presence of thiocyanate.

Healy<sup>12</sup> reported the case of a woman aged 67 with hypertension and generalized arteriosclerosis. Before treatment the blood pressure was 205 mm of mercury systolic and 100 diastolic. She received potassium thiocyanate 5 grains (0.3 Gm) three times a day for one week. The dose was then decreased to 5 grains (0.3 Gm) twice a day. On the tenth day there was marked weakness and the blood pressure was 145 mm of mercury systolic and 90 diastolic. The drug was stopped but the symptoms progressed, the patient became profoundly weak, finally semicomatose, and died in shock nineteen days after the discontinuance of the drug. Autopsy was not performed.

Healy<sup>12</sup> also reported the case of a woman aged 63 with hypertension, the blood pressure being 200 mm of mercury systolic and 120 diastolic. Potassium thiocyanate was administered as in the previous case. On the tenth day the pressure had dropped to 170 mm of mercury systolic and 88 diastolic, but the patient felt worse than she had before the drug was given. The medication was stopped, but weakness, delirium, coma and shock ensued and the patient died two weeks after the drug was discontinued. Autopsy was not performed.

Goldring and Chasis<sup>13</sup> reported the case of a woman aged 40 who received potassium thiocyanate for hypertension in a dosage of 10 grains (0.652 Gm) daily. On the fourteenth day the patient was nauseated and weak. On the fifteenth day she was confused and her speech was incoherent. Administration of the drug was accordingly discontinued, a total of 9.77 Gm having been given in fifteen days. The blood pressure continued to be high, and the following day the patient was violently delirious with hallucinations of sight and hearing, extreme motor restlessness, nystagmus and frequent convulsive movements of the extremities. She

was completely disoriented, continually muttering and thrashing about so violently as to require mechanical restraint. During the last twenty-four hours she voided almost no urine and became profoundly stuporous. Death occurred sixty-six hours after the thiocyanate had been discontinued. Even on the day of death the blood pressure had not dropped. At autopsy the lungs showed congestion, there was a pericardial effusion, cardiac hypertrophy and an inactive mitral stenosis. The kidneys showed nephrosclerosis with profound arteriolar sclerosis and the brain was edematous.

Goldring and Chasis<sup>13</sup> also reported the case of a woman aged 56 who, because of hypertension, received potassium thiocyanate in a daily dose of 12 grams (0.805 Gm) a day. After taking a total of 14.9 Gm in eighteen days she complained of nausea. The thiocyanate was immediately discontinued, but forty-eight hours later nervous manifestations almost identical with those described in their other patient developed. This state persisted six days before death occurred. Autopsy was not performed.

This communication records another death from potassium thiocyanate and has added interest in that the level of the blood cyanates was controlled. The danger of potassium thiocyanate therapy becomes more apparent when it is realized that untoward symptoms occurred while the blood cyanates were at a supposedly nontoxic level.

#### REPORT OF CASE

B W, a Negro woman aged 71, admitted to the Cleveland City Hospital Oct 5, 1936, complained chiefly of headache. She had had increasing hypertension and progressively severe headaches since 1930. On examination the patient was well developed, well nourished and neither acutely nor chronically ill. She weighed 57 Kg (125 pounds). The ocular fundi showed marked vascular sclerosis but no hemorrhages. The heart was slightly enlarged, there was a systolic murmur at the apex. Neurologic examination was negative.

The leukocytes, erythrocytes and hemoglobin were normal, urinalysis gave negative results. Reactions to the Wassermann and Kline tests were negative. The level of the blood urea nitrogen was 12.3 mg per hundred cubic centimeters. A concentration test showed the urine to have a maximum specific gravity of 1.022, a dilution test showed a minimum specific gravity of 1.003. The electrocardiogram showed left axis deviation. Numerous blood pressure readings averaged 250 mm of mercury systolic and 120 diastolic.

Beginning Oct 8, 1936, the patient received potassium thiocyanate 5 grains (0.3 Gm) daily. The blood cyanates rose from zero to 3.8 mg per hundred cubic centimeters on October 13. The following day the potassium thiocyanate dosage was increased to 5 grains (0.3 Gm) twice a day. October 19 the blood cyanates were 10.1 mg per hundred cubic centimeters. The blood pressure had not fallen in fact, on that particular day the systolic value was 300 mm of mercury.

The dosage of potassium thiocyanate was raised to 5 grains (0.3 Gm) three times a day on October 20. The following day the blood cyanates were 13.6 mg per hundred cubic centimeters and it was noted that the patient was agitated and apprehensive at times. The next day she was definitely psychotic, being noisy, excited, resistive and restless. She had delusions of persecution and various sorts of hallucinations. The potassium thiocyanate was discontinued, the patient having received a total of 135 grains, or 9 Gm, of the drug in fifteen days.

The next day, October 23, the blood cyanate level was 18.7 mg per hundred cubic centimeters. The blood pressure had not fallen. The patient was still noisy and mentally confused and required restraint. There was little change the following day, the patient muttering incoherently, making convulsive movements of the extremities and refusing food. October 25 the blood cyanates had fallen to 15.6 mg but the patient showed no improvement. She received food and fluids by means of stomach tube and hypodermoclysis.

During the next four days the patient's condition changed but little. October 29 the cyanates were 9.4 mg per hundred cubic centimeters of blood. October 30 the patient passed into coma and died. Death occurred nine days after the onset of the psychosis and eight days after the discontinuance of the thiocyanates. Terminally there was clinical evidence of bronchopneumonia at the base of the right lung. No dermatitis was noted at any time.

#### AUTOPSY

External examination revealed no abnormality. On section the viscera were found to be normally placed. The heart weighed 425 Gm. Except for hypertrophy there were no abnormalities. The aorta showed moderate arteriosclerosis. The lungs showed hyperemia and edema. There was a patchy bronchopneumonia in the right lower lobe posteriorly. The kidneys weighed 110 Gm apiece and showed arteriolar nephrosclerosis of moderate severity. The brain was completely normal externally, and on section there were no areas of encephalomalacia, hemorrhage or glial proliferation. The cerebral arteries showed slight to moderate arteriosclerosis. The remaining viscera showed no abnormalities.

Microscopic examination of the various viscera confirmed the diagnosis made on gross examination. There was generalized arteriolar sclerosis of moderate severity.

#### COMMENT

The observations of others and the case here reported indicate that the thiocyanates possess considerable potential toxicity. In general, from experiments on animals and from a study of human fatalities it can be said that death due to the thiocyanates is preceded by a rather characteristic train of symptoms and signs. In animals this consists of intense irritation of the spinal cord, in human beings there is in addition an associated toxic psychosis.

The case here described presented manifestations similar to previous human fatalities and comparable to those described in animals. The patient showed mental and physical excitement, delusions of persecution, disorientation, hallucinations, confusion and convulsive movements of the extremities. Finally coma and death occurred. The pathologic examination gave similar results to those of the three previously reported autopsies on patients who had died of thiocyanate poisoning in that there were no characteristic anatomic changes.

The case is especially instructive in that the psychosis began when the blood cyanate level was 13.6 mg per hundred cubic centimeters. During the psychosis the highest value of the blood cyanates was 18.7 mg per hundred cubic centimeters and this had fallen to 9.4 mg the day before death.

It has been stated by Barker<sup>1</sup> that the "optimum therapeutic level would seem to range between 8 and 12 mg [of cyanates] per hundred cubic centimeters of blood" and that "significant toxicity begins to appear at from 15 to 30 mg." Barker found that "toxicity increased rapidly above the blood cyanate level of 20 mg but that serious manifestations were not noted until levels of from 35 to 50 mg were reached."

This case indicates that the blood cyanate level can not be completely relied on as an indicator of the point at which toxic manifestations may appear. In this patient, toxic manifestations appeared when the blood cyanates were at a supposedly nontoxic level. Apparently certain persons, for reasons which are not clear, show an idiosyncrasy to the cyanates and have little if any margin of safety between the therapeutic and the toxic dose. Since such instances of intolerance to the drug cannot be recognized in advance, use of the thiocyanates, even when controlled by determinations of the blood level, must be considered dangerous.

## SUMMARY

This case presenting fatal toxic manifestations of the thioeynates is especially significant in that untoward symptoms occurred while the blood eynates were at a supposedly nontoxic level. Death was apparently due to an idiosyncrasy to the drug and, since such intolerance cannot be recognized in advance, thioeynate therapy must be considered dangerous.

CROSS INFECTION IN PNEUMOCOCCIC  
PNEUMONIA

JULIEN E. BENJAMIN, M.D.  
JAMES M. RUEGSEGGER, M.D.  
AND  
FANNY A. SENIOR  
CINCINNATI

Pneumonia presents another instance in which medical science is attempting to prevent disease before its pathogenesis is clearly understood. The cause of lobar pneumonia was discovered many years ago. Not only have recent bacteriologic and immunologic studies of the pneumococcus and its products made possible a much better understanding of the pathologic picture but, in the field of therapeutics, results have been so promising that already attention is being focused on the prevention rather than the treatment of the disease. Yet, despite these advances in our knowledge, no accurate information exists as to how the disease is contracted. Hence prevention for the present must be largely empirical.

As with many other diseases of the respiratory tract, the high incidence of morbidity during the colder months of the year has long been noted. Obviously this exciting cause does not suggest any angle of attack. For many years lobar pneumonia was considered a primary disease. Recently, however, it has been found on careful study that in a majority of instances a cold or infection of the upper respiratory tract precedes pneumonia. Here the approach to the problem of prevention resolves itself into one of mass policing or mass education as to general hygienic principles.

From the standpoint of etiology, two reservoirs of infection present themselves: patients and carriers. Pneumonia has long been classed as a contagious disease, yet it is rarely a reportable disease and the general failure to segregate or isolate patients with pneumonia implies that its contagiousness may be either underestimated or even mythical. In the midst of a pneumonia program at the Cincinnati General Hospital the importance of the patient as a source of infection was emphasized by several incidents, always by implication but with sufficient force to preclude the ignoring of this factor in the control of the disease. We are therefore reporting in some detail several series of cases.

In the course of studies<sup>1</sup> of the diagnosis and treatment of the pneumonias according to types, conducted at the Cincinnati General Hospital during the past three

years, those in attendance were so impressed by the fact that cross infection occurred in the open wards that now all pneumonia is treated as though contagious. Occasionally members of the family of a patient afflicted with pneumonia contracted the disease. Careful scrutiny of the data gathered brought out some interesting features concerning epidemiology.

Unless pneumococci are identified by type, such studies as these cannot be made, as any suspected cross infection must be verified by a homologous invasion in all those concerned. In presenting the contagious aspect of the disease, certain arbitrary categories, into which the cases fall, have been set up. Category 1: Epidemics in dormitories. Category 2: Disease contracted in the hospital: (a) patient to patient, (b) patient to doctor and (c) in the laboratory. Category 3: Disease contracted within the family (in the home): (a) simultaneous infection, (b) patient to nurse and (c) from a family carrier.

## CATEGORY 1. EPIDEMICS IN DORMITORIES

During the peak of the economic depression there existed in Cincinnati two bureaus for the care of homeless men, one for the local inhabitants and a federal one for transients. The inmates, ranging in age from 16 to 55 years, slept in large dormitories. Overcrowding was one of several unfavorable factors, for the buildings were merely lofts made ready for emergency use. Epidemics of type I pneumonia were encountered in each dormitory as shown in table 1.

It is noteworthy that the outbreaks occurred in the two buildings, at some distance from each other, suddenly and at about the same time and that the epidemics stopped equally suddenly. Two deaths occurred in each group. All patients were received and treated at the Cincinnati General Hospital.

The following November there was another outbreak at the Federal Bureau, Armleder Building. There were in residence at the time several hundred men. Within one month nine patients were admitted to the hospital, as shown in table 2. Of this group, all recovered. It is of interest that patient 50 was admitted in both the February and the November outbreak from the same dormitory with the same type of the disease.

Unfortunately many valuable data are missing. The proximity in the dormitories of one person to another is not known, nor is information available as to the number of carriers of type I pneumococci among the inmates. The actual number of men who had infections of the upper respiratory tract is not known, but that many had colds is definitely established. This agrees with the observation of Smilie,<sup>2</sup> who found that colds may be a factor which determines the transfer and establishment of type I and type II pneumococci from the infected to the uninfected.

CATEGORY 2. DISEASE CONTRACTED IN THE  
HOSPITAL

A. *Patient to Patient*.—We have abundant evidence that hospital contacts are frequently infected from pneumonia sufferers. In Smilie's<sup>3</sup> studies he concluded that only about 2 per cent of the hospital contacts contracted the homologous disease. This of itself would justify segregation of infected persons. In table 3 are listed all the patients treated in the medical wards of the Cincinnati General Hospital in two years whose

infection definitely pointed to the fact that it was contracted from another patient in the same ward who had a homologous type of pneumonia. The patients listed were all hospitalized for some reason other than pneumonia and were unfortunately infected after their admission. Thirteen were treated in the winter of 1936-1937, which so significantly emphasized the contagious aspect of the disease that a technic for isolation or segregation was soon enforced. Only two of the patients were treated in the winter of 1937-1938, a most encouraging sign that our precautions have reaped their reward.

It might be of interest to report that in the winter of 1936-1937, when thirteen patients with cross infection were encountered in the medical wards, there were also five patients with pneumonia who had been admitted to the hospital for other illnesses but whose pneumococcal infection could not be traced to any other patient.

The following winter, 1937-1938, after rigid precautions had been enforced and when only two patients had pneumonia which could be attributed to cross infection, there were just two patients with pneumonia which developed in the medical wards whose infection could not be accounted for.

Space does not permit a detailed account of every case listed in table 3. Just a few of them will be briefly mentioned.

CASE 57—W B, a Negro aged 41 with asthma, had been in the hospital five days when he was seized with symptoms of pneumonia and his temperature rose to 104 F. He died a few days later notwithstanding the administration of 140,000 units of serum. On each side of him and in an opposite bed

were patients who were seriously sick with type II pneumonia and had been in the ward with him for several days. The position of these patients is shown in the accompanying diagram.

Position of patient 57 in the ward

Not all the patients who contracted pneumonia in the ward were as completely surrounded as this one by patients harboring the type of organism that proved to be the infecting agent, but perfect isolation was not

TABLE 2—Second Epidemic of Type I Pneumonia Among Transients at the Armleder Building

Case No	Age	Admission	Discharge
48	34	11/ 9/35	11/20/35
49	39	11/20/35	12/ 4/35
50	28	11/23/35	12/ 4/35

54	27	12/ 3/35	12/16/35
55	33	12/ 8/35	12/13/35
56	36	12/13/35	1/14/36

in practice and the same nurses and physicians were in attendance on all. As the diagram indicates extra beds were placed down the center of the wards in order to accommodate more patients during the heavy service of the winter months. The ward capacity was thus increased 15 per cent. This represented overcrowding, as the wards were not designed for the extra number. As all medical patients are cared for in the open wards of a general hospital, it was decided that the overcrowding meant an undue hazard for cross infection and the custom is no longer permitted.

CASE 58—A S, a Negro located two beds distant from patient 10, had been in the hospital thirty-three days for clinical study. The diagnosis was periarthritis nodosa. Very suddenly five days after patient 57 was infected, the temperature rose to 104 F and pneumonia developed. Pneumococci of type II were found in the sputum. He died within fourteen hours, although he was given serum immediately.

CASE 59—C P, a white youth aged 18, who contracted two infections while in the ward, was admitted to the hospital Dec 21, 1936, with a diagnosis of acute rheumatic fever with myocardial and endocardial damage. His temperature, due to rheumatic fever, gradually returned to normal and remained so for twenty-one days. Otitis media then developed, followed two days later by pneumonia, with a temperature of 105 F. Type II pneumococci were found in the sputum. With homologous serum good results were promptly obtained. After eight days his temperature rose again, his condition became much worse and examination of the sputum revealed type III and type II pneumococci, with a preponderance of the former. The patient recovered. In the same ward at this time and close by were two patients with type II and two patients with type III pneumonia. The order of infection in this instance is most striking and leaves little doubt that patient 59 was infected twice from patients already sick with the disease.

While cross infections have been due, in the majority of cases, to type I and II pneumococci, instances were encountered in which other types have been responsible.

CASE 60—O H, a white woman aged 62, admitted to the hospital Dec 31, 1936, suffering from bronchial asthma, Jan 7 1937 suddenly showed alarming signs of pneumonia and died five days later. There were three other patients with type III pneumonia in the ward at the same time, one directly opposite her. These three patients had had their infections for several days prior to the onset of the disease contracted in the ward.

CASE 61—S H, a white woman aged 65, admitted to the hospital Dec 14, 1936, with a diagnosis of diabetes and myocardial failure, Jan 10 1937, suddenly showed severe symptoms of pneumonia. Type VII pneumococci were found in the sputum. There was another patient in the ward at this time, two beds distant, who had a type VII infection. She had been admitted January 5.

CASE 62—W O, a white man aged 47, admitted to the hospital Sept 18 1936, for a malignant growth in the abdomen, contracted type VIII pneumonia. October 29 with severe bacteremia. Five days previously, October 24 a patient had been admitted to the same ward seriously sick with type VIII pneumonia. One other patient with type VIII pneumonia was in the ward at this time.

In these cases and in the cases cited in table 3 infection could be traced to a patient in the ward who had primary pneumonia of a homologous type.

*B Patient to Doctor*—The following case is illustrative of infection from patient to doctor.

CASE 63—E G, a white man aged 26, an intern in the medical service, who had an acute exacerbation of chronic

instruments was neglected. She recalled that she had thoughtlessly handled instruments which had been used on a mouse infected with type VII pneumococci and without washing her hands had been putting cough lozenges in her mouth. Her recovery with serum was prompt.

#### CATEGORY 3 DISEASE CONTRACTED WITHIN THE FAMILY

It has been shown<sup>3</sup> that 20 per cent of immediate family contacts harbor the homologous strain in the nasopharynx. That a certain number of these carriers actually contract the disease is likewise true.

#### A Simultaneous Infection—

CASES 66 and 67—G H, a white woman aged 47, was admitted to the hospital Jan 9, 1937, critically ill with type II lobar pneumonia. The infection was an overwhelming one, with bacteria present in the blood and spinal fluid. She had been sick for ten days and died January 11. E H, her husband, a white man aged 48, admitted Jan 10, 1937, with severe type II pneumonia had been ill for one week. His infection was just as overwhelming as his wife's, with bacteremia and invasion of the spinal fluid. He died nine days later.

sinusitis Oct 2 1936 first examined and administered serum to a moribund patient with type I pneumonia. During the procedure the patient coughed in his face. One week later October 9 he showed severe signs of pneumonia found to be due to type I pneumococci. He made an uneventful recovery. During the interval of a week he had examined no other patient with pneumonia.

In this instance a conjecture as to the incubation period could be made. In the other cases cited this important period was ill defined. Apparently it must vary for the different types and the same types under varying circumstances.

*C In the Laboratory*—That those working with infectious material in the laboratory must be constantly protected seems self evident. Two instances of infection contracted in this manner are of interest.

CASE 64—C D, a woman aged 29, a laboratory technician early in September was testing some type I antipneumococcus serum for mouse protection titer. She was suffering severely with hay fever at the time and, owing to the necessary frequent use of handkerchiefs while at work, was probably careless in her technique. She suddenly showed symptoms of otitis media. Type I pneumococci were recovered from the exudate.

CASE 65—E F, a woman aged 32, a laboratory technician who showed signs of acute lobar pneumonia due to type VII pneumococci March 28, 1936 for one week had had a cold involving especially the trachea. Three days before the onset of pneumonia the gas was temporarily turned off in the laboratory and for a brief time the sterilizing of equipment and

The following instance of the simultaneous infection of two elderly sisters is of unusual interest because their infections produced symptoms and signs so strikingly similar.

CASES 68 and 69—Mrs E S, a white woman aged 65, a private patient of Dr Leon Schiff, had been sick for several days. She lived alone with her sister, Mrs H, aged 68, who ministered to her needs during her illness. Mrs E S died Dec 6 1936. Throat swabs and blood cultures revealed an infection due to type IV pneumococci. X-ray examination showed consolidation of the upper lobe of the right lung. No sputum could be obtained. Mrs H fell ill December 7, and the course of her illness followed in almost every detail that of her sister. In each case the disease had to be diagnosed by means of throat swabs and verified by blood cultures and roentgenograms. Both patients had involvement of the upper lobe of the right lung and one sister followed the other in death within a few days.

We have in our series one other instance of simultaneous infection.

CASES 70 and 71—M H, a Negress aged 48, and J H, a Negro aged 42 husband and wife, were admitted to the hospital Dec 26 1937, with type VIII pneumonia. Both received rabbit antipneumococcus serum and both had an immediate crisis with subsequent recovery.

#### B Patient to Nurse—

CASE 72—D C, a white woman aged 47, a nurse, admitted to the hospital Jan 17, 1937, with well established lobar pneumonia due to type V pneumococci, twelve days previously had

contracted a cold. Four days later she was called to nurse a patient sick with pneumonia, whom she attended for four days. The patient she was caring for was sent to the hospital January 13 and was found to have type V pneumonia with bacteremia. (In spite of serum therapy she died January 14.) The nurse made an uneventful recovery after the administration of serum. The train of events seems clear. Undoubtedly the nurse was infected by a virulent homologous organism from the patient she was attending. The incubation period would seem to have been eight days.

CASE 73—E L, a woman aged 50, had nursed for one day her son, aged 23, who was admitted to the hospital Jan 20, 1938, with type II pneumonia. January 24 she had a chill, and February 2 she came to the hospital with type II pneumonia.

This case corroborates Smillie's<sup>3</sup> one day exposure theory.

C From a Family Carrier.—It is probable that persons who have recently recovered from pneumonia may serve as carriers for a protracted period. Three patients encountered in these studies were of the immediate family of a patient who had returned from the hospital after recovery from a homologous infection.

CASE 74—E C, a white woman aged 54, was admitted to the hospital May 6, 1936, with a diagnosis of type I pneumonia and was discharged May 26. Two weeks after her homecoming her husband, C C, aged 54, was admitted to the hospital with pneumonia, also of type I.

CASE 75—E R, a white woman aged 44, was admitted to the hospital Feb 26, 1936, and "signed herself out" March 16. She had type II pneumonia, and just five weeks after her return home her son, H R, aged 16, was admitted to the hospital, also suffering with type II pneumonia.

CASE 76—J C, a white youth aged 20 admitted to the hospital March 23, 1938, had had a severe chill March 19. He had type XIX pneumonia of the lower lobe of the left lung. Seven days before, his child P C, had returned from the hospital after having the same type of pneumonia, with empyema.

These three instances immediately suggest the advisability of taking material for culture from the nose and throat of each patient convalescing from pneumonia before discharge from the hospital.

#### COMMENT

Physicians are, so to speak, at the halfway mark in the campaign against the pneumonias. Early diagnosis according to the specific etiologic organism and prompt administration of the specific curative serum have been conclusively shown to reduce the mortality in a most impressive manner. In the Cincinnati General Hospital in the nine years previous to the organized use of curative serum, the crude mortality rate from the pneumonias was between 30 and 50 per cent. The crude mortality rate has now been reduced to 11 per cent, and only those patients sick ninety-six hours or less have been serum treated. This figure represents an analysis of 600 cases observed during a three year period.

The 300 or more deaths from lobar pneumonia which are recorded each year in Cincinnati occur preponderantly between November and May, when most of the diseases of the respiratory tract are prevalent. When the first few cases appear we invariably stop to discuss the possible source of infection. While little is known of the incubation period of the infection and many other important features, it is reasonably sure that the disease is spread by two agents: (1) carriers of virulent type-specific pneumococci,<sup>4</sup> who may infect their contacts,

producing either (a) pneumonia or (b) simple carriers, and (2) patients with pneumonia who infect contacts with homologous strains.

While Smillie and others have doubted the probability or likelihood that a patient with pneumonia infects another person, ample proof has been recorded to assure the fact that this happens not infrequently. Only those patients are included in this report who showed evidence of having contracted their disease by cross infection. Many others for whom proof was not so conclusive, have been omitted. This being the case, and it seems unimportant whether the disease is highly contagious or not (tuberculosis is not), each patient with pneumonia should be regarded as a focus for the spread of the infection. The care of each patient should include those measures which have been found serviceable in the treatment of other communicable diseases.

It is essential that each patient be segregated in a cubicle and not treated in the open ward. Physicians and nurses should be required to observe the same precautions in caring for such patients as are usual in contagious disease wards. The wearing of gowns and masks and the washing of hands after each examination or treatment should be strictly enforced. Visitors to the patients should likewise be protected. Since these regulations have been adopted at the Cincinnati General Hospital, we have been convinced of their merits.

The part played by colds and other diseases of the respiratory tract, such as asthma, sinusitis and hay fever, may not be finally established. However, in these studies it was felt that colds have a definite relationship to the prevalence of homologous types of pneumococci in contacts with lobar pneumonia. This was particularly noted in the two epidemics reported in dormitories. While it may be truer of types I and II, as pointed out by Smillie,<sup>4</sup> it occurs with other types.

While overcrowding *per se* may not be a predisposing factor in the spread of pneumonia, our studies indicate that the disease exists in greater numbers under this condition. The two epidemics mentioned occurred when persons were crowded in dormitories. Only type I pneumonia was encountered in these outbreaks.

In a report which will appear later it will be shown that by far the greatest number of cases of pneumonia as well as the greatest number of deaths from the disease occur in a certain few census tracts where not only are overcrowding and economic conditions the worst in the city but also the incidence of other communicable diseases is the highest.

#### CONCLUSIONS

1 Pneumococcal pneumonia, a contagious disease, may infect contacts with homologous strains. This report indicates that physicians, nurses, other patients and other members of the family may be the victims.

2 Pneumococcal pneumonia should be treated as a contagious disease in the hospital and in the home and as a public health problem in the city. All cases should be reported by type.

NOTE.—In a study of the pneumonias in private hospitals two instances were noted of a husband and wife who entered the hospital on the same day with the same type of pneumonia. In one pair the diagnosis was type I pneumonia and in the other type IV pneumonia. Another example of family infection was in a man aged 48 who entered the hospital with type I pneumonia and was followed in five days by his daughter, aged 17, with the same diagnosis. A case of type II infection was encountered in which both the sister who was nursing the patient and the doctor contracted the disease. The patient and doctor both died but the sister recovered.

POSTOPERATIVE PARATHYROID  
TETANYCOMPLETE CONTROL OF THE MANIFESTATIONS  
BY MEANS OF DIHYDROTACHYSTEROI  
REPORT OF A CASE

H M MARGOLIS, MD

PITTSBURGH  
AND

GILBERT KRAUSE, MD

BRADDOCK, PA

The case of postoperative parathyroid tetany that we are reporting here merits, we believe the attention of the practitioner because of the dramatically efficacious control of the disease effected by means of dihydrotachysterol (A T 10) whereas every form of treatment attempted previously was without any beneficial result. There are, moreover, few reports in the American literature dealing with the clinical use of dihydrotachysterol in the treatment of postoperative parathyroid tetany.

Despite all precautions and meticulous surgical technique, postoperative parathyroid tetany, following subtotal thyroidectomy, still occurs in about 15 per cent of cases. The prevailing impression that with the advent of solution of parathyroid an answer was found to the problem of controlling every case of parathyroid tetany has been shown, as in the case to be reported here, to be erroneous. Although parathyroid tetany may yield readily to treatment with adequate dosage of calcium and cod liver oil, cases occur in which there is no improvement under such treatment and among these are some which are refractory even to the addition of apparently adequate amounts of solution of parathyroid.

## REPORT OF CASE

**History**—A white man aged 30, married, seen July 28, 1937, complained of loss of weight, palpitation, nervousness, restlessness and insomnia. These symptoms dating back to May 1937, began with loss of weight of slight degree at first but more pronounced in the four weeks previous to admission. Thus from an initial weight of 190 pounds (86 Kg) in May 1937 there was a decline to 180 pounds (81.6 Kg) in June and to 147 pounds (66.7 Kg) in July 1937. He complained of marked nervousness and stated that he was restless and fidgety and unable to sleep. He had also become subject to palpitation and shortness of breath on usual exertion during the previous year. There were no other significant complaints. The past medical and family history were essentially negative.

**Physical Examination**—The patient was well nourished and appeared extremely restless and fidgety. There was only the slightest exophthalmos but a pronounced staring expression of the eyes and somewhat increased blinking but no edema of the eyelids. The thyroid was not palpably enlarged and bruits could not be heard over it. There was marked tachycardia, the pulse rate averaging 105 per minute. The heart was normal, except for the rapid rate. The blood pressure in millimeters of mercury was 135 systolic and 65 diastolic, yielding a higher pulse pressure than normal, characteristic of hyperthyroidism. There was moderate weakness of the quadriceps muscles. Physical examination was otherwise entirely negative.

Urinalysis determinations of hemoglobin, erythrocyte and leukocyte counts and the Wassermann and Kahn tests revealed essentially negative results. Roentgenograms of the chest revealed some cardiac enlargement but were otherwise negative. A substernal thyroid was not visualized. The basal metabolic rate on admission to the hospital was plus 93 per cent.

A diagnosis of exophthalmic goiter (diffuse hyperplasia of the thyroid) was made, and treatment with compound solution

of iodine 10 minims (0.65 cc) three times a day was instituted preparatory to subtotal thyroidectomy. The treatment otherwise consisted of rest in bed, a high caloric diet and sedatives as required.

Subsequent determinations of the basal metabolic rate yielded the following readings: August 3, after seven days' treatment with compound solution of iodine, +65 per cent; August 9, after thirteen days of this treatment, +65 per cent; and August 11, after fifteen days of this treatment, +44 per cent.

Examination August 11 revealed marked lessening of the degree of thyrotoxicosis. The patient volunteered that he felt much improved, he was less restless and nervous and the pulse rate was slower. Despite the basal metabolic rate of +44 per cent, it was felt that the clinical condition was entirely satisfactory for thyroidectomy to be performed.

**Operation**—Subtotal thyroidectomy was performed August 12, the greater part of both lateral lobes being excised, leaving a small remnant of thyroid gland in the tracheo-esophageal groove on each side.

**Histopathologic Report**—The specimen consisted of thyroid gland tissue in two pieces, each measuring 4 by 3 by 2 cm. The gland was firm in consistency and on being sectioned presented a somewhat beefy appearance. There were no discrete nodules. Microscopic sections revealed areas of marked hyperplasia with poorly stained colloid. The cells were of the high columnar type and, in certain areas, more than two layers deep. Other parts presented involuted areas with dilated acini, little colloid, flattened epithelium and occasional areas of lymphocytic infiltration. The histologic appearance was that of hyperplasia of the thyroid with involution.

**Subsequent Course**—September 21, sixteen days after dismissal from the hospital the patient was seen by one of us (H M M), at which time the patient stated that almost immediately after he left the hospital marked tingling in the hands and feet and frequent spastic contractures of the fingers, toes and muscles of the calves of the legs developed. This occurred even at rest but was aggravated by activity. Driving an automobile had become almost impossible because of the frequent spasms of the leg muscles. He had gained 5 pounds (2.3 Kg), slept well and felt perfectly well in every other way. The patient recalled that during his postoperative period at the hospital he had noted slight, intermittent tingling in the extremities but those symptoms were so mild and evanescent that he did not mention them at any time.

His attending physician (G K), who had seen the patient because of these complaints shortly after dismissal from the hospital, diagnosed postoperative parathyroid tetany and prescribed calcium gluconate and later calcium lactate<sup>1</sup> in doses of two teaspoonsfuls (8 Gm) three times a day. The symptoms were not relieved, however, and the carpopedal spasm was, in fact, apparently becoming more and more pronounced.

Examination September 21 revealed no evidence of thyrotoxicosis, the staring expression was gone and there was no exophthalmos. The pulse rate was 84 per minute, the blood pressure 115 systolic, 90 diastolic. The Chvostek and Trousseau signs were markedly positive, indicative of moderately severe parathyroid tetany.

Urinalysis was negative and the blood count was normal. The serum calcium (Kramer and Tisdall method) was 9 mg per hundred cubic centimeters of blood and the serum phosphorus (Bell and Doisy method) 5 mg per hundred cubic centimeters of blood.

Because of the subjective and objective manifestations of tetany, despite the normal concentration of serum calcium at this time, the dose of calcium lactate was increased to three tablespoonfuls (45 Gm) a day, and lactose in doses of 1 drachm (4 Gm) three times a day was prescribed in an attempt to lower the phosphate level of the blood. One capsule of cod liver oil and viosterol, three times a day, was also given.

October 6 the patient reported that despite strict adherence to the prescribed therapeutic regimen he had experienced no relief, annoying and frequently severe tetany having occurred almost continuously. Examination again confirmed the existence of tetany: the Chvostek and Trousseau signs were still

<sup>1</sup> The calcium medication at this time and throughout the period of observation was given between meals.

markedly positive. Solution of parathyroid (Collip) was added to the previous therapeutic regimen in doses of 0.5 cc (50 units) daily, with the suggestion that it be increased to 0.75 cc (75 units) daily if necessary. The patient was taught to administer the injections of the solution of parathyroid himself.

Feb. 21, 1938, the patient was still complaining bitterly of the disability caused by tetany. Despite the daily use of 75 units of solution of parathyroid, plus the large doses of calcium lactate, lactose and halibut liver oil and viosterol taken, he had had, he complained, a great deal of tetany in the hands, legs and, more recently, also in the muscles of the throat and larynx. There were, in addition, prims in the muscles all over the body, he tired easily, had a tendency to drowsiness in the daytime and was gaining weight, the weight having risen from 142 pounds (64.4 kg.) before operation to 177½ pounds (80.4 kg.).

Examination again revealed signs of marked tetany, with pronounced positive Chvostek and Trousseau signs. He had become quite obese and the face was pudgy. There was a distinct exophthalmos of slight degree and puffiness about the upper eyelids. There were no clinical manifestations to suggest either myxedema or hyperthyroidism, however. The basal metabolic rate at this time was minus 5 per cent. The serum calcium was 6.2 mg., serum phosphorus 5.5 mg. and blood cholesterol 200 mg. per hundred cubic centimeters of blood. A blood count was normal.

The dose of calcium lactate was increased to six tablespoonfuls and was administered in divided doses six times a day. Cod liver oil, in doses of a tablespoonful three times a day, was given in place of halibut liver oil and viosterol capsules, but since the patient did not tolerate cod liver oil well he resumed the halibut liver oil and viosterol medication after several days. He continued the ingestion of lactose and the subcutaneous injections of solution of parathyroid in doses of 0.35 cc (35 units) twice a day.

The symptoms of tetany continued practically unabated, however, and were becoming more and more burdensome to the patient. He complained of much general weakness, in addition lacrimation associated with definite proptosis of the eyes and persistent edema of the upper lids had developed. Again there were no indications of hyperthyroidism or

TABLE 1—Calcium and Phosphorus Concentration in Blood Serum Before and After Institution of Treatment with Dihydrotachysterol

Date	Serum Calcium, Mg. per 100 Cc.	Serum Phosphorus, Mg. per 100 Cc.	Dihydrotachysterol, Daily Dose	Symptoms of Tetany
9/22/37	9.0	5.0	None	Marked
2/22/38	6.2	5.5	None	Marked
4/7/38	6.0	5.5	None	Marked
4/12/38	6.0	7.4	None	Marked
4/14/38	7.1	6.6	None	Marked
4/15/38			1 cc	Marked
4/16 and 17/38			0.5 cc	Marked
4/18/38	10.0	6.7	0.5 cc	Slight
4/19/38			1 cc	Very slight
4/20/38	10.0	7.0	2 cc	None
4/21 and 22/38			2 cc	None
4/23/38 8 a. m.	11.0	6.0	{ 2 cc	{ None
4/23/38 1 p. m.	10.1	6.9		
4/23/38 10 p. m.	10.8	7.2		
4/29/38	9.0	6.2	1 cc	None
6/7/38	8.1	6.6	10 drops every other day	None

myxedema. The skin presented numerous dry, scaly areas over which there were numerous minute, dry, papules.

Owing to persistence of tetany and our inability to control its manifestations despite a seemingly adequate intake of calcium, halibut liver oil and viosterol, and solution of parathyroid, the patient was readmitted to the hospital April 5 for closer observation and for a trial of dihydrotachysterol if necessary.

While he was in bed for several days and receiving one and one-half tablespoonfuls of calcium lactate six times a day and one capsule of halibut liver oil and viosterol twice a day as well as a low phosphorus diet, spasms of the muscles of the face, hands feet and glottis continued. There was definite hypocalcemia and an increased concentration of phosphorus, the values ranging from 7 to 7.5 mg. of calcium per hundred

cubic centimeters of blood, and of phosphorus from 7.6 to 7.4 mg. per hundred cubic centimeters of blood (table 1). After a period of ten days without any indication of the slightest improvement, treatment with dihydrotachysterol in addition to the medication previously prescribed was instituted in the dosage given in table 2.

After three days of treatment with this drug, during which time he had consumed a total of 13 cc of dihydrotachysterol, the blood calcium concentration reached a level of 10 mg. and the blood phosphorus a level of 6.7 mg. per hundred cubic

TABLE 2—Course of Dosage of Dihydrotachysterol	
Date	Dosage
4/10/38	3 cc daily
4/16 to 4/18/38	0.5 cc daily
4/19 to 4/20/38	7 cc daily
4/21 to 4/24/38	2 cc daily
4/24 to 5/2/38	1 cc daily
5/21/38 to date	10 drops every other day

centimeters of blood (table 1). He felt much improved, there being but few symptoms of tetany.

Four days later, after an intake of an additional 15 cc of dihydrotachysterol, he was practically entirely relieved of tetany except for slight spasm of the fingers of the right hand in the morning, on arising, this lasting but a minute or so, after which he could get around and exercise without precipitating tetany. He was dismissed April 24 entirely relieved of his tetany, taking six tablespoonfuls of calcium lactate, two halibut liver oil and viosterol capsules, and 1 cc of dihydrotachysterol daily.

Since dismissal from the hospital he has remained entirely free from tetany and has been able to resume his former occupation. The skin has resumed a normal appearance and texture and the blood calcium concentration has remained normal, although the blood phosphorus level, when last seen June 7, was 5.6 mg. per hundred cubic centimeters of blood. On examination he presented the faintest Chvostek reaction on both sides, which disappeared after several consecutive attempts to elicit it, the Trousseau sign was absent. He still complained of excessive lacrimation, and exophthalmos, measuring 25 mm. on the right and 26 mm. on the left, was still present. He was also found to have hyperopia with astigmatism in both eyes, for which adequate correction with glasses was prescribed.

COMMENT

Dihydrotachysterol (C<sub>24</sub>H<sub>400</sub>) is derived from tachysterol, a chemical fraction of irradiated ergosterol which exerts a specific and profound influence on the concentration of calcium in the blood. It is available under the designation A-1-10 in the form of a clear oily solution which is stable indefinitely and is suitable for peroral administration. The use of dihydrotachysterol for the treatment of postoperative parathyroid tetany was introduced first by Holtz,<sup>1</sup> and among the clinical reports of its use are those of Snapper,<sup>2</sup> Campbell<sup>3</sup> and Arnold and Blum.<sup>4</sup>

Like solution of parathyroid, dihydrotachysterol causes a rise in the calcium level of the blood, but unlike the relatively transitory effect of solution of parathyroid the action of dihydrotachysterol begins more slowly and is much more prolonged, the action of a single dose extending at times over many days. Because of this prolonged action of dihydrotachysterol it has found a most useful place in the clinical management of various forms of postoperative tetany. More important still is the fact that peroral administration

of a small amount of the drug can, as in our case, effectually control the disturbance of parathyroid insufficiency even when all other recognized means previously available including the use of solution of parathyroid, are entirely ineffectual. Solution of parathyroid must moreover, be given by injection, whereas dihydrotachysterol is effective when taken by mouth. Another advantage of the latter drug is that, once the blood calcium level has been restored to normal, frequent administration is unnecessary, small maintenance doses sufficing to prevent recurrences.

In the case reported here, treatment with large doses of calcium lactate, lactose, halibut liver oil and viosterol and solution of parathyroid was without the slightest effect on the clinical symptoms. The patient's manifestations of tetany were in fact progressing despite these measures and he had reached a state of marked disability, not to say danger, with the appearance of spasm of the glottis just before the administration of dihydrotachysterol was begun. By the fourth day of the administration of this drug however, the symptoms of tetany were strikingly anchored and within six days all manifestations of tetany, except the slightest symptoms for a minute or so on rising had disappeared. The rapid control of all the clinical manifestations of parathyroid insufficiency, as well as a return of the blood calcium and phosphorus levels to normal, was strikingly dramatic and most gratifying both to the patient and to ourselves. The therapeutic effect in our case was not less dramatic than that of insulin in the control of diabetes. It has been particularly gratifying to observe the continued maintenance of the improvement attained by the administration of as small a dose of dihydrotachysterol as ten drops every other day. The disappearance of the trophic cutaneous changes which had begun to appear was not only gratifying in itself but suggested also that by maintaining complete control of the parathyroid insufficiency indefinitely we might possibly also avert the development of cataracts, which otherwise appeared as another threatening menace.

Whether such perfect control of parathyroid insufficiency as was effected in our case by dihydrotachysterol can be uniformly achieved in every instance of parathyroid tetany remains to be learned from wide experience with this drug.

The toxic effects of overdosage with dihydrotachysterol have been reported to be essentially the same as those of overdosage with parathyroid extract and other calcium mobilizing factors. The manifestations of overdosage are languor, anorexia, nausea and vomiting, and, if more pronounced, there appear also headache, stupor, ataxia of the lower extremities, thirst, albuminuria and exanthems. These symptoms are associated of course, with hypercalcemia, which may range upward from 13 mg of calcium per hundred cubic centimeters of blood. The toxic manifestations of overdosage generally yield to cessation of further administration of the drug, bed rest, a liberal intake of fluids, and laxatives. Control of the symptoms of overdosage and a return of the calcium level of the blood to normal may require a number of days. Close observation of the patient and frequent determinations of the calcium concentration of the blood at the start of treatment

and at intervals thereafter are essential to avert overdosage, because the drug has some cumulative action. It is probably best to keep the calcium level of the blood at the lower border of normal, that is, between 9 and 10 mg per hundred cubic centimeters. By careful observation and frequent checking of the calcium and phosphorus concentrations in the blood in our case we have aimed at and achieved complete control of the parathyroid insufficiency without inducing hypercalcemia and its attendant toxic manifestations.

#### SUMMARY

The case reported is one of postoperative parathyroid tetany, refractory to treatment and progressively more disabling, despite the use of large doses of calcium, halibut liver oil and viosterol and solution of parathyroid, in which the symptoms were promptly and entirely relieved and the metabolic effects of the parathyroid insufficiency were satisfactorily controlled by means of dihydrotachysterol.

The therapeutic effect of dihydrotachysterol in the control of parathyroid insufficiency in our case was not less dramatic than that of insulin in the control of diabetes.

## SYPHILIS AND THE LAW

WITH A DISCUSSION OF THE FALSE POSITIVE  
BLOOD SEROLOGIC TEST

JOHN H. STOKES, M.D.

AND

NORMAN R. INGRAHAM, JR., M.D.

PHILADELPHIA

The United States, following its well known predilection, is on the edge if not actually near the crest of a wave of legislative enactment in a newly discovered though very old public health field that of venereal disease control. It therefore behooves the physician who wishes to understand, influence and cooperate to be informed on many as yet little appreciated aspects of the problem.

#### THE LAW IN ENACTMENT AND IMPLICATION

Law on the question of the transmission of infectious disease rests fundamentally on police powers conveyed by the legal enactments establishing state boards of health and supported by favorable decisions in the courts on issues involving quarantine and the protection of the public against the dissemination of infection. On this broad legal base rests a structure of local ordinances varied occasionally by legislative supplements from higher sources, so to speak, as in more sweeping types of laws governing groups such as food handlers and barbers. In many instances the local ordinances thus far tend to concern themselves principally with special groups of public employees such as policemen and firemen, in whose selection and welfare the state exercises some medical power. Rules adopted by private industrial concerns would not find place among existing laws because of their lack of connection with the police power, but they have nonetheless substantial force by way of the hiring and firing or job control

7 Since our report was submitted for publication MacBryde has reported seven cases in which the symptoms of tetany and the chronic hypercalcemia were controlled with dihydrotachysterol. MacBryde C. M. The Treatment of Parathyroid Tetany with Dihydrotachysterol. J. A. M. A. 111:304-307 (July 23) 1938.

From the Department of Dermatology and Syphilology, University of Pennsylvania School of Medicine and the Institute for the Control of Syphilis, Hospital of the University of Pennsylvania, state department of health cooperating.

of the employable population. The most recent type of enactment, essentially a product of the widespread public agitation and interest caused by a campaign against syphilis, has taken on both a broader sweep and a more sketchy disposition of powers and responsibilities. Amateur and unguided lay legislative handiwork can easily be recognized in some of the marital and pregnancy enactments now in existence. It is not improper to point out that medical persons unfamiliar with the diseases which it is planned to control by legislation, and even public health officers in similar situations may be responsible for confusion, injustice and unenforceability in the laws or regulations to which their efforts give birth.

#### PURPOSES OF LEGISLATIVE ENACTMENT

All law, and public health law in particular, should be an expression of educated public demand and should arise not from waves of fear, sentiment, hysteria or propagandist activity but from the broad base of intelligent comprehension of the problem involved. Yet law may also subserve an educative function. Probably the fairest statement of a practical relationship between educated demand and educational possibilities is that a law should be drawn by educators and educated or expert persons for purposes of teaching as well as for the function of enforcement and protection. In the case of syphilis there exists a sufficient body of expert knowledge as to what constitutes public health protection and a sufficient unanimity of opinion on treatment control to make the framing of sound legislation practically<sup>1</sup>. Such a statement could hardly be made, under existing knowledge, for example, of a disease like gonorrhea or venereal lymphogranuloma.

World experience with venereal disease control by law also affords some important sidelights on the background of legislative enactment. The United States is at the moment drawing its practice largely from Scandinavian example. The Scandinavian plan of venereal disease control is probably the oldest in the world, the most thoroughly systematized, and rests on the firmest foundation of national character, national homogeneity and national intelligence of any body of health legislation in the world. It is essentially an enforcement plan which takes education for granted. It is perhaps to be expected that from Scandinavian sources the legislatively minded will draw inspiration which unfortunately is not always as effective in a new

milieu as its proponents expect, it is not received by nor has it the educational and constructive effect on a different type of mind that those who frame it desire. In contrast with the Scandinavian technique and reaction stand the experiences of countries like Great Britain and the Netherlands, in which law and enforcement play a negligible part. Successive surveys of the situation in Great Britain and the Netherlands have disclosed results apparently practically equal to those of the Scandinavian countries. The inference that among such peoples as the British and the Dutch practically no fabric of legal enactment is necessary to secure adequate venereal disease control, at least in the field of syphilis, is as important for us as is our Scandinavian model. While the comparisons drawn, for example, by the recent British commission under Colonel Harrison<sup>3</sup> between Scandinavian and Dutch-British practice lack some of the absolute control features which might be desired, particularly in the direction of a long standing statistical summarization of the years preceding active public health interest in venereal disease in Britain, and to an even greater extent in the Netherlands, it is a fair inference that figures which show an almost identical trend when placed side by side and yet which are obtained by two apparently diametrically opposite methods of approach deserve careful study by framers of syphilis laws. It is a matter for real questioning whether the patchwork population of the United States will learn more and learn it better under a regime of legislative definition and enforcement than they would under an intensive application of educational methods through the press, through medical authorities and through public health agencies, lay and official, and most of all through the educated patient himself.<sup>4</sup>

Since it seems for the moment almost inevitable that the legislating technique will for a time have the upper hand in this country, it may be well to indicate the principles that the law must recognize with respect to syphilis if it is to remain at all in harmony with the known practicalities of the situation, medically speaking, as well as from the standpoint of public health.

It would seem, first of all, that laws regulating the control of syphilis should take account of the enormous variability in individual cases and the positive necessity for expert medical interpretation wherever a serious question arises. Laws governing syphilis will tend to be too specific and drawn in too great detail. So far as they preserve the right of the state to allow its public health officers to decide by individual local or official regulation in a flexible manner the processes of enforcement and judgment, subject to cooperative interpretation by the court, they are likely to be good. So far as the enactments tend to define in days and weeks and to specify in degrees of positiveness and negativeness of specific tests, they will tend to run into difficulties both in the infliction of injustice on individuals and in unenforceability in the light of expert testimony in the courts. It is therefore worth while for any one who contemplates the advocacy of legislation for the control of venereal disease to read with care the model of a venereal disease control law prepared as long ago as 1921

by the American Social Hygiene Association.<sup>5</sup> This law in its essentials does little more than define the venereal diseases as infectious and communicable, call for their reporting for statistical purposes and relegate the control of the diseased patient to competent medical authority. Since the infectious person is deprived of certain fundamental rights, provision must be made by the state as depriver for a restoration of those rights following the administration of adequate treatment. Since such treatment is by inference the condition on a restoration of full individual rights, it must be provided regardless of the economic status of the individual, in other words, free. The same provision applies in the model law to diagnosis, both clinical and laboratory. They must be freely available to all. Having thus placed the status of the infected person below that of the non-infected and provided for a free means of restoration to full or normal status, the state may then, and only then, proceed to enforcement, namely, the isolation of the infected person during his period of infectiousness, if necessary, without his own volition if he is recalcitrant or negligent. An additional very proper and necessary provision in sanitary and *ipso facto* in venereal disease control law is power to investigate the source of infection. This implies of necessity, and in the modern acceptable laws is provided for specifically by an authorization to compel, the examination of an individual reasonably suspected of being infected with a venereal disease. The alternate to refusal is isolation or quarantine.

Precisely at this point will come some of the difficult questions of interpretation in individually contested cases, if past history in this type of legislation is any guide. Generally speaking, the police power of the public health officer has been maintained by the courts when persons of doubtful reputation have been involved. Another practical situation of serious implication for the ultimate value of law in this field arises here. Anticipating failure of support from the courts on the purely medical issue of infectiousness, there has been a marked tendency on the part of some public health authorities to shift from the sanitary to the moral ground in controlling persons with venereal disease, remanding the individual to custody for criminal conduct as distinguished from public health necessity. The ultimate implications, both for education and for enforcement, of this obvious shift from the public health to the moral point of view, especially in the field of venereal disease, already so gravely encumbered with sexual stigma, is a matter for serious thought. It should influence not only the drawing of legislation but the reaction of both public health officers and courts toward its enforcement. The fact that morals charges in general hold in the practice of the court against women but cannot be made to hold against men (or at least have not been made to do so) introduces still another element of injustice and public health inadequacy into the legal practice in this field.

Let it be accepted, then, that a proposed law should be drawn in sufficiently general terms to permit an adequate exercise of individual expert medical judgment and provide for public health expediency in the individual case without invading the province of morals. In thus allowing adequate exercise of expert medical judgment it is a further though unfortunate necessity

that some provision must be made for the prevention of evasion through connivance between patient and physician. This contingency is well met in the New Jersey law,<sup>6</sup> for example, which grants to the health officer of the jurisdiction power of review over medical decisions in individual cases, and even power to appoint his own medical examiner to check the original findings.

Within this framework of legal and philosophic generalities one may now proceed to put a venereal disease control law to work. The medical principles with respect to syphilis which all law enforcement must recognize are essentially these:

First, no single test or single procedure uncontrolled or unchecked should be allowed to make a diagnosis of syphilis. This applies even to the dark field identification of *Spirochaeta pallida*, a procedure on which even the reasonably experienced may make serious mistakes and over which some form of control of expertness in judgment should be exercised. It should be further a clearly defined principle that serologic syphilis and clinical syphilis from the standpoint of public health are by no means identically significant. There exists a serologic syphilis which has virtually no public health significance, and there exists a clinical syphilis without serologic confirmation which is of the highest importance from the standpoint of the transmission of the disease. Framed briefly for everyday use, such a principle might read that the positive blood test is never an arbiter of the question of infectiousness versus noninfectiousness, and the negative blood test may be found under any and all circumstances to be without any significance whatever. It follows, therefore, that law and regulatory practice in the control of syphilis which makes the result of the blood test, checked or unchecked, false or true, the arbiter of decisions involving the civil rights and individual freedom of persons cannot stand critical review in the courts of a liberty loving and intelligently guided people. Such a law is subject to constant though variable miscarriage and abuse not only through the shortcomings of the laboratory procedures on which it rests as such but through misinterpretation which takes no account of clinical facts. The congenital syphilitic man or woman, particularly, who has reached adult life with an irreversibly positive blood reaction for syphilis can suffer all the penalties of the law with little or no justification. The patient with a primary lesion still in the seronegative stage or an infection reduced to temporary invisibility and serologic negativity by inadequate treatment can be a public danger of the first magnitude and yet remain entirely outside the control of a law so drafted.

A second principle based on the characteristics of syphilis as a disease and one which when confronted in its full meaning is extremely embarrassing to venereal disease control officers is the definition of infectiousness and noninfectiousness. Deeply though we all desire it, it must be conceded that no absolute definition of noninfectiousness and no means of infallibly attaining it exists at the present day. There will always be in practice patients who have had sufficient treatment to exceed a reasonable standard of control of infectiousness, who are still periodically relapsing and periodically infectious. Conspicuous in this uncontrolled and uncontrollable group is the woman with syphilis. As with gonorrhea, the definition of noninfectiousness may

<sup>5</sup> Social Hygiene Legislation Manual publication 312 New York Am. Social Hyg. A 1921 p. 63. Johnson Bascom. State Laws and Regulations of State Boards of Health Which Deal with Venereal Diseases J. Social Hyg. 24: 514 (Nov.) 1938.

<sup>6</sup> The Venereal Disease Control Law chapter 253 N. J. P. L. 1918 as amended by chapter 261 N. J. P. L. 1933 (section 7) New Jersey State Department of Health circular 154 (revised) August 1933.

be tantamount to the definition of cure, and cure by present methods be undemonstrable or even unattainable save over a period of years amounting to a lifetime. In this field again, public health practice finds itself obliged by the practicalities of the situation to deal with averages and mass results rather than to be too finicky about the details or even the occasional injustice done an individual person. It is therefore one of the first duties in research on syphilis to attempt to define broad categories of infectiousness and noninfectiousness. To this end the United States Public Health Service with the assistance of the Cooperative Clinical Group has been particularly active. Even though one is driven to the point of saying that the standards of noninfectiousness as secured by treatment must be identical with the expectancy standard for cure, one has not uttered something absolutely unpractical. The standard of cure has a 90 per cent validity, with a little more than one third more treatment required than the so-called 20-20 or minimum standard of treatment for infectiousness. Somewhere between the minimum and the maximum within the next several years one may expect a public health median to be drawn beyond which the exceptions will be few and far between and not difficult to provide for by appropriate special judgment and methods, much as in the case of the "typhoid Marys."

Let it then be clearly realized that special legislation for the control of venereal disease should not be written to depend purely and simply on laboratory tests. The factor of expert medical judgment must be drawn into the phraseology in a way to provide for a necessary latitude in interpretation, yet without permitting escape of the individual through a loophole of professional ignorance or connivance.

Finally, a group of facts connected with syphilis which as yet has received virtually no consideration in legislative enactment and which perhaps can be left out of the main framework of law entirely is that of the damaged goods aspect of the disease. Syphilis is, in an as yet not clearly defined proportion of cases, a reducer of efficiency and a producer of hazard and disability in life, in industry and in the social order at large. The person who has a syphilitic infection may fail his family at the critical juncture of its life history, he may fail his fellow workers in an executive post, he may fail the public at the head of a fast-moving train, he may fail a co-worker at a critical or dangerous point in industrial machine and other processing, he may even fail a patient as his physician or surgeon.

Inclusive law on venereal disease control might well take account of these relationships within the broad field of industrial syphilis.<sup>7</sup> If it does so, the protection of the worker against the very understandable but sometimes overexercised disposition of the employer to protect himself from the injured or defective employee, the sometimes hysterical desire of the clientele or the public to be protected from imaginary risks, the unwillingness of the employee to sustain the risk of refusal of employment or discharge from a job already satisfactorily held merely because of the identification of concealed and possibly industrially unimportant disease must all have equal weight.

#### THE MARRIAGE AND ANTEPARTUM TESTING TYPE OF LAW IN THE LIGHT OF THESE PRINCIPLES

At this writing nine states have actual laws regulating venereal disease with respect to marriage, and fourteen additional states in 1938 considered bills to amend their marriage laws or to impose various restrictions. In only four of the latter states have such bills been passed and become laws. An excellent digest of today's legal situation on this front is given by Bascom Johnson.<sup>9</sup>

The barrage of questions to which syphilologists have been subjected by state health officers suddenly confronted with the obligation to enforce insufficiently studied legal enactments indicates quite clearly some of the difficulties likely to be encountered. It is obvious that a law in an individual state is not sufficient to meet the situation. Until legal enactment becomes general throughout the country, evasion must inevitably be expected. Since it is extremely difficult to define the amount of treatment which cures syphilis and impossible at this writing to define exactly what cure is, marriage legislation should limit itself to the use of the term "noninfectiousness" if it proposes to withhold license to marry as long as a person can be regarded as capable of transmitting the disease. The practical difficulties in the way of even such a seemingly modest requirement are well realized by the public health authorities of this country, and they have not yet been adequately met.

While marriage laws in respect to the transmission of venereal disease, similar to those which are being enacted by the various state legislatures in this country, have been in existence in the Scandinavian countries for a number of years information as to their effectiveness is not apparently readily available. One gains the impression from the report of the survey conducted by the British Ministry of Health<sup>10</sup> that the penal code invoking punishment for exposing others to risk of infection through marriage or otherwise is seldom invoked and that when action is taken the proceedings are abandoned before sentence is passed in a large proportion of cases.

Realists in the matter of marriage legislation directed toward preventing the transmission of an infectious disease must continue inevitably to draw the distinction between marriage *de facto* and marriage *de jure*, which must be part of the everyday thinking of the syphilologist. The fact that sexual intercourse has preceded application for the certificate is such a commonplace that it is a question whether the mere withholding of its issuance until a medical examination is performed has more than a small fraction of the preventive significance which is attached to it. As a freer or more indiscriminate sexual practice tends to prevail, the virtue of marriage legislation will diminish, and it will be relegated to the function assigned to it by Hall<sup>10</sup> in an examination of marriage laws a number of years ago—that of an educational agent. It becomes essentially a chance for a fatherly talk with the doctor who draws the blood.

Here, however, the American medical profession will confront squarely its clinical obligations to the disease.

<sup>10</sup> Hall, F. S. Medical Certification for Marriage. An Account of Administration of Wisconsin Law as It Relates to the Venereal Disease. New York. Russel Sage Foundation 1925.

Certain it is that the decision as to the advisability of marriage in the case of syphilitic persons in many individual cases cannot be left to the ignorance of some practitioners or even to specialists in other fields. It is therefore necessary that those charged with enforcement make known to the public in some satisfactory fashion the existence and whereabouts of referee authorities to whom persons with doubtful or individualizable cases may go for opinion. This part of a state mechanism in the control of venereal disease is too easily overlooked by public health officers and should be made a matter for critical study and organization.

The ultimate question as to whether the state can on any serologic grounds at least, and perhaps even on any combination of clinical and serologic grounds, definitely and finally, or even indefinitely withhold permission to marry must ultimately be decided by the courts. As syphilologists we must take a definite stand against the validity of purely serologic criteria in decisions of this sort. In fact the showdown may find us astride the fence as to whether individual cases can ever reach a clearcut decision by any method of refereeship. If the law is pushed to this extreme at any point public health policy with reference to the control of infectious disease will have a critical review such as it has never sustained in all its past.

#### COLLATERAL FACTORS IN HEALTH AND VENEREAL DISEASE CONTROL LAWS

The operability and effect of venereal disease control legislation is materially influenced by a number of considerations, some of which become evident only on an actual attempt at enforcement of previously framed legislation or ordinance. An excellent example and one of the oldest so far as American practice is concerned, is the so-called food handlers' law, which is in existence and enforced with varying degrees of effectiveness and ineffectiveness in a number of states and cities in this country. From a collection of this legislation examples of practically every good, bad and indifferent mode of framing can be drawn. The usual procedure is to lump together those engaged in occupations having personal contact as an essential part of their activities and those engaged in the handling of food. The New York State law as circularized to district state health officers makes no mention of food handlers and limits its positive listing by specification to any occupation involving intimate contact with children or as nurse, domestic servant, barber, hairdresser, chiropodist, manicurist, bath attendant or masseur.<sup>11</sup> A provision requiring isolation for syphilis of any patient who conducts himself so as to become a menace to public health is perhaps sufficiently broad to cover many special groups. The New York City regulation, however, more broadly drawn and approaching by way of the general principles governing the control of infectiousness, forbids any person in an infectious stage of a disease from eating or drinking in any hotel, restaurant, drugstore, saloon or other public eating or drinking place. As to occupations, it specifies the manufacture of foods, drinks, beverages, cigars, tobacco, liquor, smoking pipes, cigar or cigaret holders and toothbrushes intended for human use.<sup>12</sup> The New

Jersey law as amended in 1933<sup>13</sup> again uses the broad provision that no person with a venereal disease in an infectious stage shall conduct himself in such a manner as to expose others to the infection. Under this heading specific prohibitions of employment are provided for those who are engaged in the preparation, manufacture or handling of milk, milk products or other foodstuffs. Such persons shall not be employed or permitted to work in any dairy, creamery, milk depot or any other place where milk or its products are produced, manufactured or sold, or in any other place or establishment where foods are exposed or handled. No person having a venereal disease in the infectious stage shall engage in the nursing or care of children or of the sick, or in any other occupation of such a nature that his infection may be transmitted to others. The blanket rider in the last sentence certainly gives plenary authority for use and abuse. The Pennsylvania state law, one of the older types lists occupations from which persons may be excluded because of infectious disease and merely includes syphilis among the number. The periodic control with reference to health of individuals employed, for example barbers, in the state of Pennsylvania apparently lies with the Bureau of Professional Licensing, which with respect to syphilis acts under the following quotation: "Such applications shall be accompanied by an affidavit which shall be made by a practicing physician and shall set forth that the applicant was examined, that a test of his or her blood was made, and that he or she is free from all contagious and infectious disease."<sup>14</sup> The vagueness of such a statement has, of course, its advantages and disadvantages from the standpoint of its enforceability, if not of the employees' protection.

The Massachusetts state law<sup>15</sup> provides an example of definite control of employability by suspension rather than by exclusion or discharge. In the specified occupations of barber, hairdresser, manicurist, waiter (or waitress), nursemaid, domestic, nurse and so on, an infectious patient may be ordered by the physician to discontinue his occupation until, in the opinion of the physician, his infectious lesions are healed. Failing cooperation on the part of the patient, the physician may refuse to assume further responsibility and the name, address and additional information regarding the patient become thereupon reportable to the state department of health.

It will be apparent that these various types of regulations range from forms which place no responsibility on the physician actually in charge of the sick person to those which place a large or even the entire responsibility on him. It may be said generally that legislation or regulation which arbitrarily specifies the indefinitely prolonged unfitness of a person for an occupation because of the presence of a disease whose infectiousness can be determined only for the individual case at the time in question is an arbitrary and possibly unenforceable type of law. That is, its enforcement is conditioned on nonprotest, and a serious contesting of its medical validity would probably lose the state its case. Regulation that places the responsibility on the physician in charge of the individual case has at least an element of fairness and, though applied by the law to

15 Regulations Governing the Reporting of Gonorrhea and Syphilis approved and adopted at a meeting of the Department of Public Health Oct. 8, 1929 amended Jan. 14, 1930 and Jan. 14, 1936 (sec. 6).

occupations in which infectiousness has far less significance than the promulgators of the law imagine, is nonetheless the more desirable type of legislation.

Some excellent illustrations of the great importance which must attach to the discretion and energy of the individual health officer and the cooperative attitude of the courts can be seen in any general study of this question. The city of Newark, N. J., for example, has a food handlers' law<sup>16</sup> calling for periodic reexamination which under the direction of an able enforcement officer has proved exceptionally workable. The devices employed for securing cooperation from uneducated persons have perhaps some slight elements of the theatrical, but in a case of this sort the means has apparently been justified by the end. The use of subpoena-like documents ornamented with the city seal as a means of giving the essential punch to an otherwise harmless summons is an excellent example of executive ingenuity. It must be clear, however, that the necessity for using such devices is a weakness rather than a strength in any type of legislation, and the effect on the courts and particularly on justices scrupulously determined to preserve the value of existing legal forms cannot always be good. It follows, therefore, that one of the first and most important influences in health law enforcement is a species of understanding between courts and health officers as to the best method for meeting the hygienic purposes of the law with due regard for the rights and liberties of the individual. The questionable value of routine food handlers' examinations in controlling the dissemination of syphilis and the other communicable diseases under the usual circumstances is well portrayed by Best,<sup>17</sup> who lists the reasons for abandoning this practice in New York City in 1934, after eleven years' active trial, as follows: 1 The average physician's examinations cannot be considered reliable. 2 The cost of adequate examination with attendant laboratory procedures is prohibitive and not commensurate with the public health benefits obtained. 3 Even though complete examinations were made, there is no assurance that the food handler will remain free of communicable disease during the tenure of certification. 4 The value of this procedure in preventing the spread of a communicable disease such as syphilis is much overrated.

Those whose experience with the field is more than casual realize that one of the chief values of the food handlers' law is to control a social group in which promiscuous sexual activity is notably frequent, and a body of individuals given to wandering and hence to dissemination of whatever infection they may carry to the public at large. One of us, during the Irvine administration of public health venereal disease policy in Minnesota, found the food handlers' law of the greatest utility in controlling waiters and waitresses not because they were food handlers but because of altogether different and far more serious activity. The instrumentality of the barber and the dining car waiter (for years practically the only individual in railroad personnel who was subject to any serious effort to recognize syphilis) in the spread of the disease is certainly questionable to say the least. Gross and improper extensions of the spread of the law when it is freed from the individual case are not hard to find. For example

A young laboratory worker, a highly trained chemist concerned purely with testing procedures, having no actual contact with milk or dairy products in which industry he was employed, lost his position on the discovery in routine serologic testing under a state law that he gave a positive Wassermann reaction. The facts of the situation made known to us by the physician who had had charge of the boy since birth were that he had a prenatal infection for which both father and mother had been adequately treated after his birth. The boy himself had had an interstitial keratitis with good recovery but with the serologic irreversibility so often accompanying this complication. His health was entirely satisfactory, his disease non-infectious, his occupation one which gave him absolutely no contact with food or with persons likely to contract a transmissible disease were such existent. There could be no more complete *reductio ad absurdum* for a blanket legal provision based on blood testing than the injustice done this particular type of individual, yet a ruling of the state attorney general cited by the company which discharged the employee absolutely closed the door on further discussion.

To be sure, public sentiment and concern with the transmissibility of syphilis will for a time aid in the enforcement of enacted legislation. This very assistance and cooperativeness of public sentiment may serve as a boomerang when a sufficient number of illustrations of the injustice and unwisdom in a poorly drawn law become known.

Under the legislation of the past decade, enforcement when projected into the courts has usually been at the expense of what might be called the relatively down and out types—persons of no reputation and questionable or "floating" standing in the community against whom it was relatively easy to secure authority from a court for summary action such as detention and quarantine. It is inevitable with the enormously wider spread of the new legislation that enforcement will be called on to deal with persons of character, standing and resource, and it is desirable that such persons contest the law in apparently contestable cases and compel interpretation by the courts of the many important principles embodied. Among the first of the issues in which legislation affecting syphilis is likely to be involved is the right to uncover health facts about an individual which do not concern a transmissible condition. It cannot be too constantly borne in mind that infectiousness in syphilis is not synonymous with positive blood tests or noninfectiousness with negative. The frank purpose of the existing marriage law is, of course, to reveal infectious syphilis, but most of the legislation is so drawn as to lay emphasis rather on the uncovering of the disease than on its identification in an infectious stage. The question as to whether any person may be obligated under any conception of civil liberties to undergo testing or examination for the mere existence of disease (and particularly disease implying, rightly or wrongly, moral turpitude) has had some consideration in the courts, and there have been decisions which have denied to a plaintiff the right to oblige a person under trial to undergo either physical examination or blood test to determine his status with respect to syphilis. It will therefore be doubly necessary, in order to protect legislation for the control of infectiousness in syphilis against adverse judicial decisions, to place the responsibility for the interpretation of the blood test and infliction of consequences not with the law itself but with the physician or a properly authorized public health representative. Without such a provision the issue as to whether a person's body is his private property and individual bailiwick will quickly

<sup>16</sup> Foodhandlers Licenses Ordinance Newark New Jersey Department of Health as adopted by the city commissioner Dec 19 1933 and amended Jan 30 and Nov 9 1934.

<sup>17</sup> Best W. H. Is Routine Examination and Certification of Food Handlers Worth While? *Am J Pub Health* 27 1003 (Oct) 1937.

become serious. It has also long been recognized by claim and damage authorities that, when a case involving syphilis is a contributory factor in compensation is brought before a jury, it is fundamentally bad policy and likely to lead to adverse decision to force the evidence of syphilis in the injured person before a jury for adjudication. The jury apparently tends to take the view that in attempting to attach syphilis to the issue the defending attorney is endeavoring to besmirch the reputation of the plaintiff and to deprive him of just compensation on a character irrelevancy. It is therefore a matter of sentiment as well as legal judgment to just what point the health authority can afford to sustain projection of such issues into the courts.

The question of secrecy and confidence, always important in medical matters, has a double importance in all that concerns venereal disease. The mere statement in the law that the record of a test will be filed in confidence with the state health authorities can be received with only qualified assurance. The access to such records is usually too widespread and the ability of persons without authority, by misrepresenting themselves as physicians or of physicians influenced by motives of curiosity and the like to secure information can hardly be satisfactorily guarded. Grapevine communication has the fluidity of electricity in these matters and it is as we have sometimes seen by personal observation, practically impossible to trace to its source what was nonetheless an indubitable leak. Not even the sequestration of records in a safe deposit vault under a single responsible control has prevented the forging of a patient's signature by a physician in behalf of the life insurance company which desired information on a blood test. There is, moreover, the ancient question of the privilege of communication and record. In a discussion of this matter by Wood,<sup>18</sup> it is made clear that the issue is a "practical rather than a legal one." Under acts of the Pennsylvania assembly in 1907 for example hospitals, which are common sources of bootleg information on syphilis, have no right to give data from their records disclosing communications with physicians attending a patient in a professional capacity or information which would tend to blacken the character of the patient without the patient's consent. The sole exceptions are civil cases brought by the patient for damages on account of personal injuries. The constant abuse of this law, exemplified by correspondence between social service agencies, for example, in which positive serologic reports are bandied about without regard to the responsibilities involved or the protection of the person concerned, is characteristic and certain to encounter serious difficulties if a wave of legal resort and interpretation once gets under way. While this confidential privilege may be waived by the patient, and such waiver might conceivably be made a stereotyped part of a contract relationship as it now so generally is in life insurance policies, it is almost certain that any court which respects the civil rights of individuals will refuse to sanction the incorporation of such blanket waivers into marriage licenses and documents of similar purport. It must be clear, therefore, that aside from the various great practical difficulties of an absolutely leaktight official filing and recording mechanism there may be serious difficulty with the question of professional privilege before venereal disease legislation is far advanced in its career.

Syphilis and the job, already mentioned briefly in the discussion of foodhandlers' regulations, presents many collateral aspects of interest for lawmakers. The right to make public an item in an employee's physical condition whether determined by physical examination or diagnostic test, has not as yet been subject to contest in the court so far as we know. The one thing that could most certainly bring it to contest in the court would be the excluding of employees from work for nonsignificant syphilitic infection. As early as the late war, from the standpoint of medical control, it was reported that the labor organizations of one of the largest industries in the country had taken a definite, though not public, stand against routine medical examination and testing for syphilis, notwithstanding that all concerned could recognize its great importance as a health hazard in the particular work involved.

Two cases very well illustrate the principles governing a situation of this sort.

An assistant cook in one of the large city hospitals was discharged by his chef with the statement that the dismissal was given because the patient had a positive blood reaction for syphilis (food handlers and similar legislation in the state of Pennsylvania). The man was told that when he had received enough treatment to give him a negative reaction he would be reemployed. Reinstatement was refused even after the patient had had considerable treatment, and the head of the clinic was privately given the explanation that the individual was rated as inefficient and was discharged for that reason, the positive blood reaction being merely a pretext. Inquiry into the individual's reputation in his job seemed to indicate that he was efficient rather than inefficient and that the motive back of the discharge was one of personal jealousy. His serologic reaction ultimately became negative, but no reinstatement has occurred to date.

This case illustrates the misuse of the law governing infectious syphilis in extending application to noninfectious syphilis, the arbitration of the individual issues, medical merits and personal rights in the case by an incompetent arbitrator—the chef in charge of the kitchen, the misuse of a positive serologic reaction as a pretext for a discharge actually based on other and personal grounds.

A kitchen worker attached to the staff of a college training table who without preliminary medical examination had been employed by the college for six months and proved to be thoroughly efficient was then subjected to a routine physical and serologic examination and the blood reaction was found to be positive by the state laboratory. As was proper under the circumstances, he was referred to the college medical clinic having charge of syphilis and was found to have a seropositive latent infection of probably not less than twenty-six years' duration, the patient being at this time 46 years of age. Before it was possible to work up the case or have a competent medical opinion on his status, the nurse attached to the training house squad discovered in some way that the patient had been referred to a syphilis clinic for study and without waiting for further information took the matter to the lay superintendent of employees in this group. The lay superintendent and nurse, again without referring the matter to the physician who had originally recognized the presence of syphilis in the employee, proceeded directly to the syphilis clinic in an effort to obtain information as to whether this employee had syphilis. Information was properly refused them on the grounds that they were laymen and that the patient was privileged in the matter of communication. Thereupon these two lay persons, considering further reference of the matter to medical authority unnecessary, took it on themselves to discharge the employee on the ground that he had syphilis and that his association with food handling work on the training table made him a public health menace. Thereupon the clinic in which the man's infection was under study went back to the physician in charge of the case with

<sup>18</sup> Wood C. B. Legal Status of the Medical Record. Bull. A. Record Librarians of North America. June 1932.

this report, and by conference with him and with the cook in the kitchen succeeded in securing the employee's reinstatement, since his syphilitic infection was absolutely without significance for the transmission of the disease.

In view of the state law under which this case would come to jurisdiction at the hands of the attorney general or the court the action of the clinic would have been overruled, since the law in this particular state was mandatory with reference to the discharge of seropositive persons who had anything to do with an occupation or industry concerned with food handling. The obvious justice of the situation would therefore have miscarried completely after a career of grapevine detective work and unauthorized summary action by noncompetent persons typical of possibilities in such situations as this.

Before proceeding to a consideration of the false positive serologic reaction in relation to syphilis laws, we shall summarize the principles thus far brought forward.

1 Legal enactment dealing with the control of syphilis should place the power of decision as to infectiousness, public industrial hazard or liability to become a public charge (the only proper case for legal control) in the hands of a physician, empowering him to waive responsibility for the patient's noncooperation by report to the state health authority.

2 The equipment of the physician for such responsibility must be made a matter of general medical concern and education and the law must provide for appeal to a recognized authority either by patient or by health officer to adjust an individual decision if such is necessary.<sup>19</sup>

3 The differentiation of the detection of infectiousness from mere uncovering of the disease in latent or harmless form can thus be preserved.

4 Provisions for the changing status of the individual with the institution of treatment, especially in terms of its effect on the blood test, should not be incorporated in the law. In their place the decision as to fitness should be individualized and left to the physician and health officer, acting together with a referee authority.

5 "Food handler" and similar class industrial legislation is an anachronism and like all types of occupationally founded discrimination in venereal disease control should be displaced by comprehensive legislation based on (1) control of infectiousness and (2) precise definition of industrial and public liability, protective of the rights of both employee and employer.

6 The practicalities involved, including the difficult issues of the privileged record, professional confidence and health status of the individual in whom infectiousness is not an issue, will for a time, at least during experimental regulation, probably best be dealt with by conference between the physicians concerned, the public health officers and the courts.

7 The wisdom of devices saving of "bluff" in enforcement, while probably real, should be carefully considered as a matter of public policy.

8 Increasingly serious questioning and contesting of health officers' and doctors' decisions in the courts may be expected and invited as the social level of those affected rises above the down and out and the "demonde."

9 Secrecy and the preservation of confidence are more real and difficult issues in venereal disease detection and control work than health officers and law framers are apt to realize. The mere enactment of confidential status does not secure it in the strict sense

of the term. It is oftener a matter of personnel. Violation or misuse of the professional relation may be made specifically and severely punishable (compare dissenting remarks by N. A. Nelson to Ramsey's section report "Public Health Control of Syphilis," Washington, December, 1936).<sup>19</sup>

10 Enactments made under public pressure, hysteria and misconception will sustain serious setbacks and induce equally misconceived opposition and reaction if injustice and violation of personal confidence and personal rights become frequent and widely known.

11 In matters involving the job current practice quite largely fails to discriminate between infectious or disabling syphilis and harmless syphilis.<sup>20</sup> In our case material there is evidence of grapevine telegraph, action without authority, disregard of medical knowledge and supervision, misapplication of medical therapeutic principles by laymen in supervisory capacities and use of results of blood tests as pretexts for personal and unfair discriminations.

## THE LAW AND INTERPRETATIONS OF THE SEROLOGIC TEST WITH SPECIAL REFERENCE TO THE FALSE POSITIVE

### THE SEROLOGIC TEST FOR SYPHILIS AS A BASIS FOR DECISION

It must be obvious from the foregoing discussion that the dependability of serologic results, and hence the quality of serologic test performance in syphilis, is critically important in all forms of legal regulation. The familiar medical tendency to regard a test tube procedure as having something of the oracular and indisputable in it is shared by laymen and lawmakers. It must be clear that a law which makes either the positive or the negative serologic test for syphilis the basis for important decisions, such as eligibility to marry, will have a validity and enforceability fundamentally dependent on the reliability of the procedure employed. A law drawn so as to make test results crucial and which uses them as a substitute for well rounded medical and expert syphilologic judgment works a fundamental injustice and is likely to be brought to book in the courts.

### INTERPRETATION OF THE POSITIVE SEROLOGIC TEST FOR SYPHILIS

For a number of years the serology of syphilis has been dominated by the laboratorian. With a knowledge of clinical syphilis based principally on the scattered facts of the history of the infection and clinical signs sent to him on report sheets, the performer of tests for the presence of syphilis has been obliged to attempt, often reluctantly, the alinement of his results with clinical facts. As the serologists, working against this thin background of clinical information, sought to increase the sensitivity and yet preserve the specificity of newly devised procedures, elements of personal equation and interpretation have unquestionably further played a considerable role. It has been difficult for serologists to accept the idea of a considerable margin of nonspecificity, especially in tests of their own devising, and it has been equally difficult for them to see called into question both the false positive and the false negative trends which are inseparable from any long time per-

<sup>19</sup> Nelson, N. A. in discussion of section report by Ramsey, G. H. The Public Health Control of Syphilis. Ven. Dis. Inform. (supp. 3) 1937, p. 78.

<sup>20</sup> Moore, J. E. Syphilis and Unemployment. editorial Am. J. Syph. Ven. Dis. 21: 339 (Mar.) 1937.

formance of serologic tests for syphilis. It was therefore of particular interest that, at the recent assembly of serologists and laboratory directors for the consideration of the problem of national serologic standardization (Hot Springs, Ark., Oct. 20-21, 1938), the syphilologists delegated to attend it, without previous consultation on the matter, joined in a vigorous demand for the revision of current concepts of the meaning and validity of the positive serologic test. The technical false positive had already had, to those familiar with the work, a sufficient airing in the reports of two government inspired national cross checkings of laboratory procedure in this country.<sup>21</sup> The results of these conferences have really shown that no justification for the diagnosis of syphilis was to be found in a number of cases in which the diagnosis had been based on what proved to be a single false positive reaction. So much importance attaches to this finding that the serologic committee reemphasized the fact that a serologic diagnosis of syphilis, unsupported by history or clinical evidence, should never be made on the basis of a single positive blood reaction. If a positive reaction is obtained in such a latent case, it should be repeated in the same laboratory or another laboratory utilizing two or more different tests.

While many state and local laboratories achieved results that are at least comparable to the results achieved in the laboratories of the originators of the methods, in some of these laboratories the results obtained were considerably inferior to those obtained with control tests and were inadequate for diagnostic purposes. After a careful review of five official evaluation studies of tests for syphilis, Nagle and Willett<sup>22</sup> concluded that no efficient test can possess less than 99 per cent specificity (excepting certain few diseases, especially malaria and leprosy) and 65 per cent sensitivity, and that ideally the specificity should approach 100 per cent even at the sacrifice of sensitivity.

The discussion of the doubtful positive reaction was illuminated by such as that of Kahn, for example, who was inclined from his personal observation to rate a two plus Kahn result as doubtful rather than positive. The recent establishment of the fact that leprosy,<sup>23</sup> malaria<sup>4</sup> and certain febrile illnesses including subacute bacterial endocarditis<sup>24</sup> and infectious mononucleosis<sup>6</sup> are all capable of giving rise to biologic false positive results in laboratory tests for syphilis is an illustration of current revision. The work of Barnett and Kulchar<sup>25</sup> on syphilitic reagin in normal blood and their apparent confirmation of the existence of a false positive provocative effect following intravenous injection of neoarsphenamine are genuine landmarks in rein-

terpretation. The latter observation is of particular interest because the attempt by Strickler and his associates,<sup>26</sup> now nearly two decades ago, to demonstrate the contention that Barnett and Kulchar have now established by more exact measurement was at that time laughed at and pounced on by clinicians and serologists alike. It was therefore particularly interesting that the trend of the discussion from the clinical standpoint at Hot Springs should have been so definitely toward the necessity for revision of our conception of the positive and especially of the doubtfully positive serologic test.

Within the past ten months there have appeared within the practice of one of us, nine typical illustrations of the complexities of the serologic interpretative problem. In a relatively small practice this is a large proportion, and the short period of time in which the material was presented probably reflects the growing acuteness of the problem under the wave of serologic testing now sweeping over the country. Brief abstracts of some of these cases and the decision reached in each will illustrate better than mere discussion the problem that confronts the public and the profession in this field today.

**CASE 1**—A chemical engineer aged 24 was placed on treatment for syphilis by his plant physician when found to have a two plus Kahn reaction on blood obtained while the patient was suffering from a rather severe sore throat. He was given an injection of neoarsphenamine and a week later a second injection. The second injection was followed by a sharp febrile episode with a profuse erythematous eruption, during which a second two plus Kahn reaction was obtained. He was told that the eruption was his secondary rash and advised to continue treatment. The examination of the patient and the critical study of the attendant circumstances, including an examination of his fiancée, made it reasonably clear that the patient did not have syphilis. The fiancée had been exposed once (the only time the patient had ever had intercourse) without acquiring the disease, though the patient was presumably in the acutely infectious stage. The rash associated with the febrile episode, which conforms in practically every detail to the Milian eighth day erythema, known to be associated with the second injection of neoarsphenamine in patients carrying some other type of infection than syphilis, disappeared in two days. While no evidence of syphilis has since been recognized, even following the most searching examination, the patient was nonetheless advised to follow through the Cooperative Clinical Group standard treatment for early syphilis<sup>29</sup> as a safety first measure.

**CASE 2**—A housewife aged 25 had a macular eruption of the chest and arms in January 1938. Serologic tests (Wassermann) performed in a private laboratory on two separate specimens of blood were reported three plus and two plus during the presence of this eruption, the Wassermann reaction of the spinal fluid being reported negative with a negative colloidal gold reaction. At this time the husband had a negative reaction. An abortion at three months was induced by the attendant physician, who told the patient that the fetus could not escape infection. The eruption which was said to have lasted three or four weeks, was apparently not seen by a dermatologic consultant. Following two injections of neoarsphenamine and three injections of bismuth subsalicylate the patient presented herself for reconsideration of her problem and the continuance of her treatment. There were no longer any evidences of the disease and no attendant circumstances confirmed the presence of the infection. Serologic reactions, most of them to Kolmer, Kline, Kahn and Eagle tests performed in a state laboratory and the laboratory of the syphilis clinic, were completely negative. A

bismuth provocative procedure was carried through (interval since last treatment, one month) with completely negative results. The patient was told that her treatment should be continued as for a secondary syphilis<sup>29</sup> even though the clinical and serologic response, the total absence of signs and confirmatory circumstances all suggested that she had been the victim of false partial positive reactions during an intercurrent eruptive condition.

**CASE 3**—A musician aged 32 voluntarily seeking a premarital examination (it turned out subsequently that he had been married the week before) had two moderate but definitely positive Wassermann reactions (Kolmer) in one of the best serologic laboratories in the country. Unwilling to accept this result, his physician subjected the situation to review by one of us with a resulting picture of serologic confusion as follows: a complete negative, followed by a weak positive and negative reaction in the laboratory which had originally found him definitely positive, a complete negative reaction in the laboratory of the University Syphilis Clinic, and a negative spinal fluid examination. A bismuth provocative effect was then obtained in which the Kolmer reaction increased from negative to strongly positive on two successive weeks in two laboratories, the Kahn reaction from negative to strongly positive in one laboratory, the Kline reaction from negative (one plus) to three plus and again negative, and the Eagle reaction from negative to partially positive. This group of results was rated as sufficient to establish the existence of an infection, and the patient was instructed to continue treatment. Painstaking investigation of the background and collateral factors disclosed only one suspicious circumstance. Eight years before the patient had had enlarged cervical lymph nodes following a "cold," with surgical removal, accompanied however by a negative serologic reaction of the blood. Clinical examination for congenital as well as acquired syphilis was completely negative.

**CASE 4**—A student aged 18 received a four plus Wassermann report as part of a physical check-up by his own physician. Immediately afterward a hospital in a different city gave the Wassermann and Kline reactions as negative, and a urologic clinic reported the Wassermann reaction a weak positive, the Kahn a weak positive and the Eagle positive. Examination of this patient by the syphilologist disclosed only a somewhat increased prominence and thickening of the right clavicle suggestive of a Higoumenakis sign, which was probably due to the fact that for three years he had carried a rifle on this shoulder two hours a day. Clinical examination for syphilis, including examination of the mother, was completely negative. Kolmer, Kline and Kahn reactions at the University Syphilis Clinic laboratory and the Kline reaction at the state laboratory were also negative. The initial serologic reaction was adjudged falsely positive and no further treatment was advised.

**CASE 5**—A pregnant wife volunteered to have a blood test made as part of an antepartum examination and a negative result was obtained. But the husband, who volunteered for a test at the same time, obtained a report from the state laboratory on two occasions five weeks apart of a negative Kline and a strongly positive Kolmer reaction. In the interval another hospital laboratory had reported the Hinton reaction negative and the Kolmer reaction negative. The patient, with whom one of us had been acquainted professionally for more than a decade, then underwent a complete examination in the University Syphilis Clinic laboratory, covering a period of five weeks and including five successive tests, which was clinically negative for syphilis (the patient was an eczema, asthma, hay fever subject) and in which the spinal fluid and a bismuth provocative procedure gave negative results. The state laboratory once more reported a partially positive Kolmer reaction but all other tests gave negative results. The patient was told that there was no convincing evidence of syphilitic infection and to report again in six months.

**CASE 6**—A woman aged 29 was denied a license to marry in a neighboring large state because her physician did not wish to assume the responsibility incurred by a report from the state laboratory of a titer of two plus, three plus and 34 units by

the state Wassermann technic in three tests over a period of five weeks. The Wassermann and Kahn reactions at a large hospital in a neighboring state were negative on two occasions three days apart. On close inquiry it appeared that the titrated state laboratory tests were taken while the patient was menstruating, when the period was just over and just at the end of the next succeeding period. The negative reactions were obtained between the periods. A complete examination of the patient disclosed no clinical evidence of the disease and no reason for suspecting its existence. Serologic reactions of the blood were negative between her periods in the laboratory of the University Syphilis Clinic. There was a remote possibility of congenital infection implied in the death of siblings in infancy but there was nothing clinically to support it. A history of some form of arthritis and an inconstant soft systolic murmur in the third left interspace were the only additional possibly significant signs. She was advised to have a blood test taken at the middle of each succeeding four lunar months, this to be followed by examination of the spinal fluid if any trace of positiveness appeared. She was warned (for she had married in another state in the meanwhile) to avoid pregnancy and to have her situation reconsidered should pregnancy occur.

#### HOW TO GO ABOUT CHECKING THE REPORT OF A POSITIVE SEROLOGIC REACTION

1 The first inquiry should be into the source of the report and the methods used. It is axiomatic, nowadays, that the report of a serologic reaction is worth only as much as the reliability of the laboratory from which it emanates and the responsibility and skill of the performer. It is not to be expected that small private laboratories or even large state laboratories operating without interlaboratory check and without clinical control will be able to render the most trustworthy reports obtainable. States in which a machinery for the serologic testing of applicants for marriage licenses or for pregnant women has been set up, or industrial organizations in which an attempt is made to provide an intramural laboratory service, should study and conform to the standards about to be set up by the United States Public Health Service.

2 The time at which blood is drawn for the test and all attendant circumstances, including particularly the presence of intercurrent and especially febrile infections, must be taken into account in interpreting test results.

3 No single positive report should ever be accepted without confirmation. Repetition of the tests in the same laboratory by the same procedure is the least searching form of check. The performance of two or even three standard test procedures may provide additional interpretative evidence, but the difficulties of the interpretation increase with the number of tests and a corresponding degree of experience and expertness becomes desirable. The sending of the blood to several laboratories is likely to increase the confusion and multiply the interpretative difficulties, though it is a proper check when conducted under sufficiently experienced direction. Nonstandard or individual modifications of standard serologic tests for syphilis (for this country the Kolmer, Kahn, Kline, Hinton, Eagle procedures may be regarded as standard) are likely to lead to confusion and uninterpretable results. This is especially true of the older multiple antigen and cholesterinized procedures.

4 Clinical examination in the doubtful case must be searching and conducted by one who is experienced in the recognition of individual, relatively unfamiliar signs such as the Moon molar and other dental anomalies, the facies of prenatal syphilis, the less obvious evidences of early cardiovascular and neurosyphilitic involvement.

It should be emphasized that the history of primary and secondary lesions taken as a routine has a margin of error ranging from 30 to 60 per cent or even higher and is practically worthless in women

5 An examination of the spinal fluid should be conducted when, in the opinion of a reasonably expert reviewer of the evidence, it is actually necessary to do so. Provocative procedure being open to suspicion at least so far as the arsphenamines are concerned, serial repetitions of the test will have to be substituted. The bismuth provocative procedure even though resorted to in the foregoing cases, likewise has elements of uncertainty probably shared by all provocative procedures and is very much in need of reappraisal. Observation is, of course, a necessary element in any decision and absolutely essential if the weight of evidence pro and con approaches "fifty-fifty," so to speak.

6 A "no case" or negative decision inevitably involves some elements of subliminal or intuitive thinking. The necessity for a genuine acquaintance with the patient whose problem is under review, with his family, with all those who may have been drawn into the syphilitic infection from the standpoint of contact, family relationship and so on, may compel one to resort to epidemiologic case finding methods.

7 The decision to treat on suspicion, while it seems an obvious resort, is nonetheless one for serious deliberation. Particularly is this so in women, for the problem of the infected woman is already uncertain enough from the standpoint of her ability to transmit the disease in a subsequent pregnancy,<sup>30</sup> and the uncertainty can be multiplied many times by half-hearted or incomplete resort to treatment. The effects of treatment on serologic tests are unreliable as evidence in doubtful cases, so that the purpose of treatment is rather the protection of the individual and his contacts than the settlement of his diagnosis. It should be emphasized again and again that therapeutic tests on doubtful genital and secondary lesions can be interpreted only by experts and are of doubtful justification and validity at that. All in all, it is probably better, if the decision is made to treat, to ask the patient to go through with the full standard therapeutic regimen for the phase and stage of the disease in which he would be were the evidence of infection indubitable. Only in this way can he be given the best assurance that modern management of syphilis affords that he will be free of complications and fit for normal responsibilities.

#### SUMMARY

From the foregoing presentation it may be regarded as reasonably evident that legislation calculated to make the recognition of a syphilitic infection a basis for conduct of any kind cannot be framed so as to place sole or even major dependence on any laboratory procedure, including a blood test. It is essential that the individual autonomy and judgment of the physician be invoked and preserved. It is the duty of the medical profession, the medical schools and public health authorities to concentrate on the development of a mechanism of adequate complete examination and expert refereeship as a necessary supplement to any attempt to control syphilis by law.

## DIABETIC GANGRENE OF THE FACE

JOSEPH MILLETT, MD

HEMPSTEAD, N Y

Gangrene of parts of the body other than the extremities is to be considered a rare complication of diabetes mellitus. Gangrene of the nasal septum and turbinates in diabetes has been described both in America<sup>1</sup> and abroad. Bulger<sup>2</sup> has described gangrene of the right half of the tongue in diabetes, Riven<sup>4</sup> a disseminated cutaneous lesion which he termed diabetic dermatitis gangraenosa, Elkin<sup>5</sup> diabetic gangrene involving the vulva, and Sturgis<sup>6</sup> diabetic gangrene of the lip.

My purpose in this report is to present the little known association of diabetes mellitus and staphylococcal gangrene of the face. A search of the literature reveals only three cases<sup>7</sup> involving the cheek, two of which closely resemble clinically the conditions to be described here. The clinical picture has been noted only casually, and laboratory and pathologic reports are either scanty or lacking. This complication of diabetes mellitus presents some interesting features regarding differential diagnosis and prognosis.

#### REPORT OF CASES

**CASE 1—History.**—A white man aged 47, a landscape contractor, admitted Jan 10, 1937, complained of swelling and redness of the right side of the face, with fever and malaise. He died January 17.

The present illness dated back to one week before admission when a head cold developed, associated with a running nose. About the same time, or shortly thereafter, he noted that the right side of the face had become slightly reddened. There was no history of trauma. The condition of the face became worse and three days before admission the right side of the face became definitely swollen and markedly red, his right upper eyelid began to swell and he felt feverish. The day before admission his right eye was closed entirely, small blisters began to appear on the lids, and on the day of admission these began to discharge pus. He was sent to the hospital by his physician with the diagnosis of erysipelas, which was confirmed by the admitting staff, and was admitted to the contagious ward with this diagnosis.

The past history revealed nothing of any moment except long-standing obesity and a known diabetic condition for the past five years. The diabetes was readily controlled by diet and by 5 units of insulin in the morning and 10 units at night. He had not seen his physician for several months previous to his present illness.

**Examination.**—The patient was obese. On physical examination he was lying in bed and was apparently quite uncomfortable. The entire right side of the face was covered with a reddened lesion which was somewhat elevated. The borders were not sharply defined. The right eyelids were edematous, the eye was closed and the upper lid exuded creamy pus from a small area. The skin of the left eyelids showed beginning redness. The rest of the examination was essentially negative.

Dr Millett was formerly resident physician at Meadowbrook Hospital. From the Medical Service of Dr Ernest Dickey, Meadowbrook Hospital.

Dr Frank L. Meleney of the Presbyterian Hospital, New York, rendered valuable aid in interpreting the clinical data and in reviewing the final manuscript.

7 Brooks G P. Diabetic Gangrene of the Face. Brit M J 2:539 (Sept 31) 1929. Bowers<sup>1</sup> Brier<sup>11</sup>.

The temperature was 103 F (rectal), pulse rate 124 and respiratory rate 28.

**Laboratory Reports.** Analysis of the urine showed albumin 2+, sugar 2+ and no acetone or diacetic acid. The microscopic examination was negative.

Analysis of the blood showed 84.5 per cent hemoglobin. The differential count of the white blood cells gave 30,600 leukocytes, with polymorphonuclear leukocytes 89 per cent, lymphocytes 9 per cent and eosinophils 2 per cent. Nonprotein nitrogen was 38 mg per hundred cubic centimeters and sugar 278 mg. The Wassermann and Kahn reactions were negative.

Cultures of material taken from the nose and throat yielded staphylococci. Eye smears showed staphylococci and gram positive rods.

**Course.**—During his stay in the hospital the patient went rapidly downhill. The temperature ranged between 101 and 104 F. The diabetes was difficult to control both by diet and by insulin. On the second hospital day the left cheek became involved. On the third hospital day the right cheek rather suddenly became purplish, and several small blisters and bullae formed which contained clear fluid. That night they broke and the next day these areas began to discharge pus. A direct smear revealed staphylococci. The lesions were treated locally by boric acid compresses and ultraviolet radiation. At no time did the patient complain of pain.

Two days before death the blood sugar advanced to 470 mg. He became comatose. Urinalysis showed sugar only 2 plus with no acetone. A blood culture taken two days before death showed 200 colonies of *Staphylococcus aureus* per cubic centimeter. The entire right cheek was a mass of purplish green slough. The patient died on the eighth hospital day.

**Necropsy.**—Permission for necropsy was obtained and this was performed fifteen hours after death by Dr. Joseph Lane of the department of pathology.

The pertinent changes were a wide area of edema and cellulitis over the entire right side of the face which was of a suffused purple-gray bearing areas of ulceration and necrosis in places. The lungs showed bilateral acute fibrinopurulent pleurisy and complete collapse of the left lung with emphysema, while the right lung showed many subpleural abscesses with a confluent lobular pneumonia involving all its lobes. Microscopic examination of the lungs revealed pulmonary congestion, edema and focal abscess formation and diffuse necrosis and patchy pneumonia. Smear of the abscesses revealed staphylococci.

**CASE 2—History.**—A white woman aged 55, a housewife, admitted March 19, 1937, complained of redness and swelling of the right side of the face and fever. She died March 22.

The present illness dated back six days before admission. The patient noted a small "boil" on the inside of the left nostril. There was considerable pain. The lesion was treated conservatively with hot boric acid soaks and opened spontaneously with free drainage and relief of pain.

The next day her lip and the skin of the nose on the right side began to feel warm, turned red and began to swell. By evening it had spread to the right cheek. This was accompanied by fever and malaise. A diagnosis of erysipelas was made by the local physician and on the following day the patient was admitted to the contagious ward of Merdowbrook Hospital.

The past history revealed a known diabetic condition for several years. She had taken as much as 15 units of insulin three times a day plus a diet for the control of the diabetes. Three weeks before admission she was seen by her physician, at which time she was on a strict diet with no insulin and was told that there was a small amount of sugar in the urine. She was told also that she had had high blood pressure for the past two years.

**Examination.**—The patient was obese. When she was being examined she was lying quietly in bed, apparently acutely ill. There was a dull red swelling extending over the right cheek and down the submaxillary region of the neck. The lesion was slightly raised and the borders were not sharply demarcated. There were two small crusts just within the left nostril of an apparently almost healed furuncle.

The temperature was 103.4 F (rectal), pulse rate 100 and respiratory rate 25.

**Laboratory Reports.** Analysis of the urine showed sugar 3+, acetone 3+.

Analysis of the blood showed 100 per cent hemoglobin. The count of the white blood cells gave 14,000 leukocytes, with polymorphonuclear leukocytes 76 per cent, lymphocytes 12 per cent, monocytes 12 per cent. The Wassermann and Kahn reactions were negative.

Cultures of material taken from the nose and throat yielded staphylococci.

**Course.**—The patient was treated vigorously for diabetic acidosis with insulin and intravenous saline and dextrose solution until the urine became acetone free. The next morning the chemical examination of the blood revealed sugar 115 mg, urea nitrogen 14.5 mg, creatine 1.5 mg. The lesion was treated locally with boric acid soaks, and sulfanilamide 15 grains (1 Gm) every four hours was given by mouth.

In spite of treatment the local lesion became worse. At no time did the patient complain of any pain. The right portion of the upper lip to the midline and the adjacent skin of the cheek began to assume, rather suddenly, a purplish gangrenous hue on the second hospital day. The patient became semicomatose. The urine showed only a 2 plus sugar and no acetone, and the blood sugar was 286 mg per hundred cubic centimeters. A blood culture taken at this time revealed a heavy growth of *Staphylococcus aureus*.

On the third hospital day the cheek and lip were definitely gangrenous, while the red lesion had spread to the right ear and down the right side of the neck. There was a slight discharge of pus from the center of the gangrenous area on the cheek. The patient died that afternoon.

Permission for necropsy was not obtained.

#### COMMENT

The diagnosis of diabetic gangrene of the face offers little difficulty once gangrene appears. Early it is mistaken for erysipelas. Brooks<sup>7</sup> and Ardeschir<sup>8</sup> specifically mention the resemblance of the lesions to erysipelas early in the course of the cases seen by them. The case described by Bulgei<sup>9</sup> might very well have been diagnosed as erysipelas from the description of the lesion before gangrene developed. When gangrene develops, the lesion resembles the entity described by Meloney,<sup>10</sup> which he called hemolytic streptococcus gangrene of the skin, and must be differentiated from it. This also resembles erysipelas in its early stages, but in these cases a hemolytic streptococcus can almost always be recovered.

Diabetic gangrene of the face does not even remotely resemble the carbuncle seen in cutaneous infections in patients with diabetes. The dramatic change *en masse* of an erysipeloid lesion in a diabetic patient to a dusky, cyanotic purple area with or without the development of blisters or bullae and the subsequent breakdown of tissue with the discharge of pus is the typical course of events.

Unlike diabetic gangrene of the extremities, age apparently plays no role in this type of gangrene. The youngest patient on record was 4 years of age, followed by one 8 years and two 10 years of age. The oldest was 65 years of age.

The underlying mechanism producing the gangrene must be quite distinct from that causing gangrene of the extremities in elderly diabetic patients, in whom chronic obliterative arterial disease is of prime importance. There are several factors to be considered in a discussion of the causes of this type of gangrene. There is devitalized tissue in a patient who is susceptible to infection because of his diabetic condition. Trauma

<sup>8</sup> Ardeschir, K. Diabetic Gangrene of the Nose. *Lancet* 1:1756 (June 26) 1926.  
<sup>9</sup> Meloney, F. J. Hemolytic Streptococcus Gangrene. *Arch. Surg.* 317 (Sept.) 1924.

to the skin, however slight, with the ever present staphylococcus, may be a precipitating factor. An acute arteritis, together with inflammation and edema in a small space, can conceivably lead to thrombosis of the small branches supplying the skin, with subsequent necrosis of the tissue and ensuing gangrene.

The organism found in our two cases was *Staphylococcus aureus*, which was recovered from the facial lesions and blood stream in both, and from the metastatic abscesses in the lungs of the patient who came to necropsy. The staphylococcus was obtained on smear from the vulva in Elkin's case, and a hemolytic *Staphylococcus aureus* was obtained on culture from the facial lesion in Bulger's case. Riven obtained pure cultures of *Staphylococcus aureus* from the blebs in his case of diabetic dermatitis gangraenosa.

From the standpoint of prognosis, gangrene involving parts of the face in diabetes is not necessarily fatal. Patients with lesions which involved the nasal septum and turbinates, the hard palate, the eyelids, the skin of the nose and ears and even the lip have recovered. Bulger<sup>3</sup> cites the case of an elderly physician with gangrene of the right half of the tongue who was living in good health five years after the excision of the gangrenous area. Only one case involving the septum and turbinates ended fatally (Bower's case 1 which was in the preinsulin era). All cases involving the cheek, including the two cases herein reported, were fatal.

The complications encountered in the cases presenting lesions involving the cheek are dependent on the route followed by the infection through the veins draining the area. If the drainage is into the general circulation, septicopyemia and metastatic abscesses are the result. However, should the infection drain into the veins leading inside the skull, cavernous sinus thrombosis, meningitis and abscess of the brain may follow. These complications are usually fatal. Complications reported with lesions on other parts of the face are the results of spread by continuity of tissue. Morris's<sup>10</sup> case involving the turbinates and septum was complicated by the involvement of the adjacent sinus and the third, fourth, ophthalmic branch of the fifth, and the sixth nerves. Brier's<sup>11</sup> case involving the skin of the ear and the area anterior to it was complicated by involvement of the fifth and seventh nerves. Ardeslir's<sup>8</sup> case of gangrene of the skin of the nose was accompanied by destruction of the underlying cartilage of the alar nasi.

Treatment in these cases is both general and local. General treatment consists of combating the diabetes and its complications with insulin, dextrose and fluids. The toxemia can be attacked by forcing fluids. *Staphylococcus* bacteriophage and antitoxin, if available, can be tried against the septicemia. Transfusions and other supportive measures must be instituted. The local treatment, except when the lesion involves the cheek, is to promote drainage and remove slough. For lesions on the cheek the policy of nonintervention seems to be the accepted surgical procedure, although the results obtained by this form of treatment are uniformly fatal. Roentgen irradiation may be tried directly over the affected area.

## SUMMARY

1 Two cases of diabetes mellitus and staphylococcal gangrene of the face reported were fatal.

2 There is a close resemblance of the facial lesion to erysipelas in its early stages and to hemolytic streptococcal gangrene of the skin in its later stages. The differential diagnosis is made by studying the organisms involved.

3 Internists and surgeons should both be aware of this complication of diabetes mellitus from the standpoint of prognosis.

4 Diabetic gangrene of the face is not necessarily a fatal disease unless the cheek is involved, with subsequent spread of the infection into the general circulation with metastasis and death.

## IMMUNIZATION AGAINST PERTUSSIS

JOHN J. MILLER, JR., M.D.

AND

HAROLD K. FABER, M.D.

SAN FRANCISCO

The prevention of pertussis is today one of the main problems of the pediatrician and school physician. Isolation of the patient as a means of preventing the spread of this disease has in general been ineffective. The nonspecific character of the cough during the catarrhal stage—which Lawson<sup>1</sup> has shown is the most infective period—makes early diagnosis virtually impossible. The cough plate is the only means of making an early diagnosis. By it atypical cases are also discovered. There are many of the latter, as the more general use of cough plates now indicates. Valuable as this procedure is, it is obviously impracticable to take plates of all children and adults with coughs. A decreased morbidity and mortality from pertussis—which now is responsible for more deaths than any other epidemic disease with the exception of influenza—can be expected only when a potent immunizing agent is obtained.

Evidence on the value of pertussis vaccine is notoriously conflicting. Since the introduction of vaccine made from freshly isolated (phase I) strains by Meyer and his associates<sup>2</sup> and by Madsen,<sup>3</sup> several favorable reports have appeared. The numerous encouraging reports of Sauer<sup>4</sup> and of some others<sup>5</sup> using the Sauer vaccine (a phase I vaccine) have stimulated widespread interest. The excellent controlled field study at Grand Rapids under the leadership of Kendrick<sup>6</sup> has provided unequivocal evidence that

immunization can be accomplished with phase I strains. On the other hand, Doull, Shibley and McClelland,<sup>7</sup> using a phase I vaccine prepared in a slightly different manner, failed to confirm the results of Sauer and Kendrick. Furthermore, Seigel and Goldberger,<sup>8</sup> using a commercial preparation of Sauer's vaccine, found that under conditions of intense and prolonged exposure protection was not clearcut.

The following field study was undertaken in an attempt to contribute evidence to this perplexing problem. In size and detailed investigation it is not comparable to the studies of the Grand Rapids group<sup>6</sup> or to the Cleveland group.<sup>7</sup> It is, however, well controlled and is sufficiently large for statistical analysis.

#### MATERIAL

Only infants and little children from 6 months to 30 months of age were studied. The majority were under 1 year. All were attending the Stanford University

the "test" group until the day after the last injection. Four instances of systemic reaction to the vaccine were observed. Fever lasted for one day.

The parents of infants in the injected or "test" group and of those in the control group were instructed to notify the clinic of any known exposure to pertussis. They were also requested to bring the patient in any time that any cough developed. The members of both groups were seen in the clinic or in the home at intervals of from three to six months. When patients were lost they were declared out of the group as of the day last seen. When pertussis developed the patient was declared out of the group as of the day of onset.

The criteria of exposure which were used were as follows:

1 The test or control infant must have played with a coughing child in the first three weeks of pertussis for at least one hour indoors.

\* On the basis of child months at risk one would expect twenty five cases in the vaccinated group not seven.

For the period October 1935 through March 1938

† Difference in communicability rates = 61.1 per cent with standard error = 13.9 per cent

‡ Difference in attack rates per child month at risk = 0.63 per cent  $\pm$  0.18 per cent

§ Difference in crude attack rates = 8.48 per cent with standard error = 2.73 per cent

For the entire period of observation

† Difference in communicability rates = 50.6 per cent with standard error = 12.4 per cent

‡ Difference in crude attack rates = 11.7 per cent with standard error = 3.0 per cent

Well Baby Clinic. Beginning in October 1935 a number of infants were injected every month. Each month a similar number of infants of the same age distribution was selected by chance. These served as controls. No attempt was made to select infants with older brothers or sisters who had not had pertussis.

The vaccine used was an unwashed suspension of freshly isolated phase I strains of *Haemophilus pertussis* grown on human blood Bordet-Gengou medium.<sup>9</sup> It was first standardized to contain 10,000 million organisms per cubic centimeter. Later the suspension supplied contained 20,000 million organisms per cubic centimeter. A total dose of 80,000 million organisms was used, i. e. 8 cc. of the first product and 4 cc. of the second product. This dose was divided into 20,000 million, 30,000 million and 30,000 million organisms and given at weekly intervals. (Occasionally the intervals were longer.) No child was considered to have entered

2 The test or control infant must have played with a coughing child in the first three weeks of pertussis at least two hours outdoors.

3 If the duration of the contact was less than this, the parent must have seen the coughing child cough directly into the exposed child's face from a distance of less than 2 feet. (There were only two such transient exposures that resulted in escape—one in the test group and one in the control group.) No child in this study was known to have been exposed more than once.

4 An "unknown exposure" is one that must have occurred when pertussis develops in a child without any known exposure.

The criteria for the diagnosis of pertussis were (1) typical whooping cough with whooping and post-tussive vomiting (cough plates and blood counts were not done in all obvious cases), (2) cough without the typical picture but in which positive cough plates were obtained.

It will be noted that three "possible" cases are included in the tables—two in the test group and one in the control group. These attacks of cough were not typical of pertussis. Cough plates were negative in

<sup>7</sup> Doull J. A., Shibley G. S. and McClelland J. E. *Am. J. Pub. Health* 26: 1097 (Nov.) 1936.

<sup>9</sup> Supplied by the Cutter Laboratories, Berkeley, Calif.

two of them and the third child was not seen until she had recovered from her cough. They are included, however, because their histories are suggestive.

Table 1 classifies at intervals of six months the number of children entering each group and the number leaving each group. It also shows the "net strength"<sup>10</sup> of each group in each six month interval and the "child months at risk"<sup>11</sup> during each interval. It is evident that the number of controls lags somewhat behind the number of test children. The child months at risk for the control group likewise lags behind that for the test group except in the first six month interval. Control children were found somewhat more difficult to follow.

### RESULTS

The results are summarized in table 1. The data are complete through March 1938. During the four months from April 1 to Aug. 1, 1938, some additional exposures and cases occurred but the follow-up data are incomplete and the figure for child months at risk during this period is unknown.

In the two and one-half year period from October 1935 through March 1938 there were in the test group twenty-six exposures followed by nineteen escapes and seven cases of pertussis, two of which are questionable. The ratio of exposures to cases—communicability rate—is therefore 26.9 per cent. For the same period of time there were in the control group twenty-five exposures followed by three escapes and twenty-two cases (one of which is questionable), giving a communicability rate of 88 per cent. The difference in these rates is 61.1 per cent with a standard error of 13.9 per cent. The standard error is less than one third of the difference, i. e., the difference is significant. The four subsequent months of observation, until August 1938, slightly increased the communicability rates in both groups, yielding a difference in rates of 59.6 per cent with a standard error of 12.4 per cent. This difference is likewise significant.

The wide difference in the ratio of exposure to disease in these two strictly comparable groups constitutes proof that the vaccine protected most of the children who received it. The difference in the attack rates in the two groups is obviously corroborative, being also statistically significant. Comment is unnecessary. The communicability rate is a more important index than the attack rate.

A comparison of the type of exposures in the test and control groups is made in table 2. A familial exposure is the most rigid test of immunity. In each group nine familial exposures happened to occur. Six vaccinated children escaped and a seventh had "bacteriologic whooping cough" without paroxysms or vomiting.

The three children who were attacked had been vaccinated at least eighteen months previously. The majority who escaped had been vaccinated for one year or less.

The three escapes occurring in the control group occurred after exposure of one day or less.

There were eleven instances of cases occurring without known exposure in the control group and only one

occurring in the test group. It is probably fair to assume that as many unknown exposures actually did occur in the test group as in the control group, for the child months at risk were somewhat greater in the test group. This assumption would increase the number of exposures in the test group from twenty-nine to thirty-nine. The ratio of attack to disease would thus be from nine to thirty-nine and the communicability rate 23.0 per cent.

A classification of the types of cases noted is shown in table 3. The "mild cases" were all verified by positive cough plates or hyperlymphocytosis. The "atypical cases" were diagnosed only because positive cough plates were obtained. The "possible" cases were unproved atypical cases, as was previously mentioned. Perhaps they should be omitted. Such an omission would alter the figures in favor of the test group.

No deaths occurred during the study. Only three cases of atypical pertussis occurred in the test group—two of these after familial exposure of one week

TABLE 2—Classification of Exposures

		Resulting	
		Cases	Escapes
Familial exposure for one week or more

Control group	3	20	4	1	1	29

or more. These three children had been vaccinated fourteen months, eighteen months and twenty months previously. Twenty-three typical or severe cases occurred in the control group.

### COMMENT

The foregoing remarks with regard to type of exposures and type of cases enhance the evidence obtained by a simple comparison of the communicability rates in the two groups. This evidence implies that the vaccine used conferred complete protection on some of the children and partial protection on others. Typical pertussis was seen in only three vaccinated children. They had been vaccinated more than one year previously.

We believe that annual reinjection with a small amount of vaccine is advisable. A solid antibacterial immunity of duration comparable to artificially produced antitoxic immunities cannot be expected. It has not been realized with typhoid or plague vaccines. Until a test of immunity against pertussis is devised, annual or at least biennial reinjection with a fractional dose would therefore seem empirically reasonable.<sup>12</sup>

12. A small number of children in the test group were reinjected with 40 billion organisms in April, May and June 1938. It so happened that none of these have been exposed since reinjection.

10. "Net strength" is a value used by Doull and his associates<sup>7</sup> which consists of the number registered at the end of the preceding six month period minus any in whom pertussis has developed plus one half of the newly enrolled and minus one half of those lost.

11. Child months at risk is the product of the number of children enrolled and the months during which they were enrolled. (A child enrolled for the full six months of each interval would furnish therefore six child months at risk.)

The time required after the administration of vaccine for the development of immunity is not known. Sauer<sup>13</sup> believes that three months is necessary. Schermerhorn<sup>13</sup> has recently presented evidence from Kendrick's study indicating that protection develops more rapidly. Madsen<sup>3</sup> has also held this opinion. In our small field study the following observations have some bearing on this point.

In the vaccinated group

A prolonged familial exposure beginning fourteen days after completion of vaccination resulted in an escape.

A transient indoor exposure nineteen days after completion of vaccination resulted in an atypical case.

A similar exposure twenty-six days after completion of vaccination resulted in a possible case.

An outdoor exposure four months after vaccination resulted in a mild case.

Two prolonged familial exposures five months after vaccination resulted in escapes.

This information is recorded without comment because of its brevity. No conclusions are drawn.

The dose of 80,000 million bacterial organisms used in this field study is that advised by Sauer<sup>14</sup> for children under 3 years of age. It is also essentially that used by Kendrick and Eldering<sup>6</sup>. Silverthorne<sup>14</sup> has recently observed almost perfect protection with a dose of 120,000 million organisms. It would seem that the quantity used is of great importance. Sauer's recommendation of a dose greater than 80,000 million organisms for older children seems rational. It is obvious that a determination of the proper dosage can only be empirical until a test for immunity is developed.

The results herein reported have been paralleled with the same vaccine in the same community by those of Singer-Brooks<sup>15</sup>. In a slightly larger vaccinated group she found a communicability rate similar to ours.

#### SUMMARY

Immunization against pertussis was attempted in a well baby clinic. Two hundred and eleven infants were vaccinated with an unwashed phase I vaccine in a total dose of 80,000 million organisms. One hundred and eighty-two infants were followed as controls.

During a period of thirty-four months there occurred twenty-nine exposures in the vaccinated group followed by nine cases and twenty escapes. During the same period thirty-two exposures occurred in the control group followed by twenty-nine cases and three escapes. The difference of 59.6 per cent with a standard error of 12.4 per cent in the resultant communicability rates was statistically significant.

Of the nine cases occurring in vaccinated children only three were typical. In these instances vaccine had been administered fourteen months or more previously. The other six cases occurring in vaccinated children were mild, atypical or questionable. Of the twenty-nine attacks occurring in the control children three were severe and twenty were typical. No deaths occurred in either group.

These observations indicate that the vaccine used conferred either complete or partial protection on the great majority of those inoculated.

Annual reinjection with a fractional dose of vaccine is advisable.

Since this manuscript was submitted one case has occurred in the test group. One case and one escape have occurred in the control group. The current communicability rate in the test group is 28 per cent as compared to 85 per cent in the control group.

## Clinical Notes, Suggestions and New Instruments

### AN OUTBREAK OF ANTHRAX INFINCTION IN MINX WITH INFECTION OF A RANCH OWNER

HENRY PINKERTON, M.D., ST. LOUIS

Anthrax infection in cattle, sheep, goats and horses has long been recognized as a potential source of human infection, and appropriate measures have been taken to protect the public against this danger. As a result of such measures, the incidence in human beings has been greatly lowered, perhaps to an irreducible minimum in many parts of the world. The anthrax bacillus is also known to be pathogenic for rabbits, guinea pigs, rats and mice, while dogs, swine, cats, birds and cold blooded animals are relatively insusceptible. The susceptibility of the mink, as far as can be learned, has not previously been reported.

In recent years the artificial breeding of minks has become an industry of considerable importance, and ranches of from 100 to 2,000 minks are widely scattered through the country, especially in the Northern states. Standard diets for these animals include fish and meat, usually horse meat because of its low price. Foxes, which are of even greater commercial importance than minks, are also large consumers of inexpensive horse meat, but no reports concerning their susceptibility to anthrax are available.

Several unusual hazards for man are associated with the occurrence of anthrax infection in minks. In the first place, the common practice of removing the pelts from any animals which die suddenly makes ranch workers extremely liable to infection, since this operation is carried out with bare hands and arms, often with the continuity of the skin broken as a result of mink bites and other types of trauma. Mink skins taken off under these conditions have in the past been sold without restriction. It seems probable that this practice introduces a serious hazard not only for the subsequent handlers of the pelts and garment workers but also for the ultimate consumer. The contact of infected mink fur with the unprotected skin in the region of the neck must be regarded as particularly dangerous.

For these reasons it seems desirable to report the following experience, which occurred incidentally to the routine microscopic examination of mink tissues for the diagnosis and control of mink distemper.

Oct. 29, 1938, a ranch owner brought to the laboratory a number of dead minks which he said were in excellent health on the preceding evening but had died suddenly with convulsions and bloody diarrhea. During that day and the two following days he lost fifty-eight animals, representing more than half of his herd. Distemper and most other common causes of death in minks were ruled out on the basis of this clinical picture. It was felt that botulism was a strong possibility, since this disease has been previously reported in minks and as a very remote possibility equine encephalomyelitis was considered, because of the recent epidemic of that disease in horses and human beings in the locality.

Autopsy was done on one mink, and all tissues, including the brain, were fixed in solution of formaldehyde. Bacteriologic studies were not made at this time. The only obvious

13 Schermerhorn L. J. Round Table Discussion at the Meeting of the American Academy of Pediatrics. Del Monte Calif. June 1938. *J. Pediat.* 13: 279 (Aug.) 1938.

14 Silverthorne L. N. and Frazer D. T. Canad. M. A. J. 38: 556 (June) 1938.

15 Singer-Brooks Charlotte H. Round Table Discussion at the meeting of the American Academy of Pediatrics. Del Monte Calif. June 1938. *J. Pediat.* 13: 292 (Aug.) 1938.

gross pathologic changes were a small amount of blood in the large intestine, a greatly enlarged, deep red spleen and cerebral congestion.

Five days later, examination of hematology and eosin stained sections of tissues from this animal showed enormous numbers of large square ended bacilli in the blood vessels of all organs. Since the tissues of this mink were fixed only a few minutes after death, the diagnosis of anthrax seemed likely and the mink rancher was warned of this probability. Unfortunately, he had pelted the last of his dead animals only a few hours previously.

The carcass of one of his minks was obtained, as were also three minks from another ranch on which a number of deaths with an apparently identical clinical picture had occurred. The postmortem picture of all four of these minks was identical with that just described, except that in one animal the spleen was much smaller, opaque yellowish white and caseous in appearance, apparently as a result of total infarction. The blood and tissues of all four animals contained large numbers of anthrax bacilli. Pure cultures of the anthrax bacillus were obtained from the spleens of all four animals, and two of these cultures proved fully virulent for mice and guinea pigs.

The dietary factor common to these two ranches and to a third ranch on which similar deaths occurred was found, on investigation, to be horse meat bought from the same dealer. A large piece of this meat, which had been buried by the rancher who brought in the first dead minks, was unearthed for study. After it had been cut in two and the cut surface seared, small fragments were removed for culture and animal inoculation. Smears and paraffin sections showed many typical anthrax bacilli. Cultures were positive for anthrax and injection into guinea pigs produced typical anthrax infection and death within forty-eight hours.

The dealer from whom the horse meat was purchased was quoted as having said that he killed a sick horse, which he used for making fertilizer, and later killed and butchered on the same floor an apparently well horse, the meat of which he sold to the mink ranchers. It is perhaps theoretically possible that meat from a healthy animal might become infected in this manner, but it seems more likely that the apparently well horse was in reality infected. In any case it was clear that the minks on two ranches and probably also on a third ranch had died of anthrax from the ingestion of infected horse meat purchased from this dealer.

The ranch owner first mentioned, three days after pelting the last of his minks, noticed a small lesion developing on the dorsum of his right hand. This lesion, when first seen, November 6, was 5 mm in diameter, with a dark red, rather scablike center and a raised, almost white periphery. There were several abrasions on the hand and arm. Although there was no redness and but little tenderness or surrounding edema, the presence of minute blebs, visible only with a hand lens, around the elevated margin of the lesion, together with the history outlined, raised a strong suspicion of anthrax infection. Immediate hospitalization was advised.

After he entered the Peter Bent Brigham Hospital, the appearance of the lesion became typical of anthrax within thirty six hours, and a definite bacteriologic diagnosis was made by withdrawing fluid from a bleb with a fine capillary pipet. Under conservative treatment, with the administration of 600 cc of serum in repeated doses and two injections daily of 0.6 Gm of neoparsphenamine, the patient made a complete recovery, which was uneventful except for a moderately severe serum reaction, with urticaria of forty-eight hours' duration. There was no febrile reaction at any time and only slight enlargement and tenderness of the axillary lymph nodes.

The frequency of anthrax infection in minks in the past and the chances of its occurring on a large scale in the future cannot be definitely stated at present. Sudden loss of a large number of minks on a ranch is by no means an infrequent occurrence, and since the possibility of anthrax in these animals has apparently not been pointed out before, it is probable that this infection has occurred in the past without being recognized and that infected pelts have been sold without the knowledge of seller, purchaser or ultimate consumer. Occa-

sional human infections of this origin may also have escaped recognition. It is of interest that the carcass of one of the fifty-eight dead minks aforementioned, which in all probability was heavily infected with anthrax bacilli, was submitted by the local veterinary to the veterinary department of a large commercial laboratory. The report returned was a frank admission that a diagnosis had not been made, in spite of careful study.

In view of the probability that the experience detailed does not represent an isolated occurrence, it is suggested that state boards of health or other proper authorities might advisedly take steps to safeguard those engaged in the mink industry, as well as the general public, against the dangers implied. The important steps would appear to be (1) more careful inspection of slaughterhouses selling horse meat to fur farms, (2) a warning to fur farmers not to pelt animals dying suddenly until the possibility of anthrax infection has been excluded and (3) burning or careful disinfection of carcasses, pelts and other contaminated objects when the diagnosis of anthrax has been established.

#### FRACTURE-DISLOCATION OF AXIS AND ATLAS IN AN INFANT

R D PADULA MD AND E J TRACEY MD NORWALK CONN

Extensive search of the literature has failed to yield any report of a condition similar to the one to be described. Treatment of the condition is evidently rare, probably owing to the small number of infants relative to the general population, to their sheltered lives and to the great opportunity for death to follow the injury before treatment can be applied. We have found our case interesting from the standpoints of cause, diagnosis and therapy.

#### REPORT OF CASE

A 4½ months old, poorly nourished white boy was rushed into the emergency room of the hospital by an excited father, who asserted that the boy had just been severely shaken by him. The house physician present at once recognized that the child was dying. He sent the nurse into the halls to look for the nearest attending surgeon, while he went about examination of the infant's chest and the administration of oxygen by means of a funnel. One of us (R D P) was immediately available. No abnormality of the chest was reported, respiration was irregular and poor, and there were cyanosis and generalized tonic spasm. Traction on the head with counterforce to the pelvis abolished spasm and allowed apparently normal respiration, while relaxation of traction resulted in a return of signs of pressure on the medulla and the cord.

Clinical opinion was that probably fracture dislocation of the atlas and axis existed. While traction and countertraction were carefully maintained, the infant was wheeled to the x-ray department, where lateral and oblique views were taken. These showed an anterior dislocation of the axis in relation to the atlas and fracture of the spinous process of the third cervical vertebra.

Treatment was instituted without interruption of the stretching of the neck. A halter for the head was fashioned of adhesive tape; the patient was laid on a firm mattress with the head of the bed elevated, a small pillow was placed under the shoulders to aid in maintaining hyperextension, and countertraction was maintained at the pelvis. This treatment continued for two weeks (during much of which time oxygen was used and the tent was always in place). Then clinical and x-ray evidence showing that reduction was maintained, a plaster Thomas collar was applied. After three weeks this was replaced with a leather and steel collar, which was permanently discarded after four weeks. At the time of writing, three months after injury the patient has apparently completely recovered from the trauma. Motion of the neck is normal and there are no neurologic signs.

#### COMMENT

This child cried till its father became so provoked that he grasped it by the pelvis and shook it severely. The forceful hyperextension and hyperflexion of the neck produced not only

From the Norwalk General Hospital

the fracture-dislocation but, in the opinion of the neurologist, a traumatic encephalitis due to punctate hemorrhage of the brain

Stress is laid on the value of history in the diagnosis of this condition. The objective signs presented were those common to a large number of conditions not the result of trauma, so that it is hardly likely that the correct diagnosis would have been made in this case had not the history of trauma led to the application of traction to the head, with the result that an almost dead patient began immediately to revive.

This case illustrates the value of care to prevent undue motion during x-ray examination and other diagnostic procedures wherever a fracture is suspected, especially in the spine and more especially in the cervical portion of the spine. Had traction been interrupted in this case during transportation about the hospital or during x-ray examination, it is believed that the patient would not have survived.

#### SUMMARY

In an infant, fracture-dislocation of the atlas on the axis would probably not have been diagnosed except by the aid of the history of trauma.

Where signs are such as can result from intercranial pressure or from pressure on the cord, and their degree is such that life is imminently threatened, fracture-dislocation in the cervical region should be considered, traction applied to the head may be life saving.

The value of splinting fractures during transportation and x-ray examination has been illustrated.

Definitive treatment of fracture-dislocation of the atlas on the axis by conservative means has resulted in an apparently complete cure in a 4½ months old child.

#### A CASE OF HYPERCHROMIC MACROCYTIC ANEMIA REFRACTORY TO LIVER EXTRACT

ABRAHAM MAHLER M.D. AND DAVID GREENBERG M.D. NEW YORK

This case of hyperchromic macrocytic anemia was fatal and is being reported here to illustrate some interesting features in differential diagnosis.

#### REPORT OF CASE

A woman aged 62 was in fairly good health except for hypertension until five months before admission to the hospital. At that time she noted unusual dyspnea on exertion, pallor and weakness, all of which increased rapidly within the following three months. Her physician found severe anemia with a high color index in the face of a normal gastric acidity, the figures being total acid 75 and free acid 58. X-ray examination of the gastrointestinal tract was negative. Since liver therapy and other measures did not yield a favorable response, she was referred to the hospital. Here one of us (D.G.) elicited the additional fact that she had received radiation therapy eight or ten times to the left breast for a bloody discharge from the nipple some ten years previously. The patient could barely speak from weakness and was unable to elaborate any further on this history.

On examination in the hospital, the following relevant conditions were noted. Very marked weakness and pallor, with moderate jaundice, were present. The temperature varied between 100 and 101 F. The red cell count was 1,350,000 and hemoglobin was 34 per cent, giving a color index of 1.26. Leukocytes numbered 6980 and the differential count showed neutrophils 64 per cent, lymphocytes 34 per cent, eosinophils 1 per cent. Blood platelets numbered 40,000. The smear showed anisocytosis with many macrocytes. There were hyperchromia and polychromasia. There were poikilocytes, normoblasts and macroblasts. The reticulocyte percentage was 6, the patient having had liver therapy before admission to the hospital.

From the medical service of Dr. David Greenberg, Jewish Memorial Hospital.

Bone marrow, by sternal puncture, showed increased megaloblastic activity with diminished numbers of normoblasts. Leukoblastic activity was normal. The number of megakaryocytes was diminished.

The icteric index was 23. The van den Bergh test gave a delayed direct reaction. Urobilinogen in the urine was increased. The fragility test showed beginning hemolysis at 5 and complete hemolysis at 4.

Bence Jones protein was absent from the urine. There was no nitrogen retention and no diabetes mellitus. There was no glossitis or atrophy of the tongue and no definite evidence of involvement of the spinal cord. The spleen, liver and lymphatic glands were not enlarged. There was no gross or occult bleeding from the gastrointestinal tract. The feces showed no ova or parasites. Pelvic examination revealed no bleeding or evidence of a malignant condition. There was no bleeding from any of the mucous membranes, nor was there evidence of a malignant growth anywhere that might have accounted for the anemia.

The patient on admission and every few days thereafter received a blood transfusion of from 250 to 500 cc. The transfusions did not halt the downward trend. Concentrated liver extract intramuscularly was given daily in doses of from 1 to 6 cc throughout her period of hospitalization, which was three weeks. There was a reticulocyte response up to 14 per cent after seven days of liver extract. This was encouraging, but the bone marrow failed to follow through with an increased output of red cells. On the contrary, each few days brought a steady decline in red cells and hemoglobin content, so that one week before death the red cells numbered 560,000 and the hemoglobin was 17 per cent, the color index 1.5, and the leukocytes numbered 11,700 with 74 per cent neutrophils.

#### COMMENT

The tentative diagnosis in the very beginning of our study was pernicious anemia, for this was indeed a severe macrocytic hyperchromic anemia, with evidence of destruction of the red blood cells, increased activity of the megaloblastic marrow and the usual alterations of the red cells in the peripheral blood. However, the presence of hydrochloric acid in the stomach, the absence of lingual signs, the absence of definite neurologic changes, the absence of the usual leukopenia and granulocytopenia and, above all, the failure to respond to hemopoietic principle all served to show that this macrocytic anemia was not pernicious anemia.

It is now generally accepted that the hemopoietic principle is absolutely necessary for the physiologic maturation of the megaloblast. An inadequate supply of it results in a macrocytic hyperchromic anemia. It is formed in the stomach by the action of the intrinsic factor—an enzyme hemopoietin secreted by the gastric mucosa—on the extrinsic factor which is present in proteins. It is not formed in pernicious anemia because of the failure of the gastric glands to secrete the intrinsic factor. This failure to secrete intrinsic factor is practically always associated with a failure to secrete free hydrochloric acid.

Since in the case reported here there was normal gastric acidity, it is safe to assume that there was no deficiency in hemopoietic principle.

In spite of a normal gastric acidity and normal production of hemopoietic principle, the bone marrow may still be unable to mature the megaloblast, and a hyperchromic macrocytic anemia may result because of a deficient delivery of the hemopoietic principle to the bone marrow, which may occur in the following three situations:

1 Diminished absorption from the intestine. Examples are sprue, idiopathic steatorrhea of adults and intestinal parasites, such as fish tapeworm.

2 Defective storage in the patient's liver. Examples are cirrhosis of the liver, acute toxic hepatitis and acute yellow atrophy.

All the clinical conditions listed under 1 and 2 were effectively ruled out by the absence of supporting history, physical signs and laboratory data. Furthermore, they were all ruled out by the failure of our patient to show a favorable physio-

logic response to adequate dosage of parenteral liver extract, for the marrow in all these conditions does respond to liver extract

3 Defective utilization of the hemopoietic principle by the bone marrow even though enough of it is made in the stomach, enough absorbed from the intestine and enough stored in the liver

This is a definite clinical syndrome and was named achrestic anemia by Israëls and Wilkinson.<sup>1</sup> It is a fatal hyperchromic macrocytic anemia. Like pernicious anemia it has a megaloblastic marrow with similar changes in the red cells of the peripheral blood, but it differs in that the leukoblastic function of the marrow is usually normal, so that there is no leukopenia or granulocytopenia. Furthermore, there are no achlorhydria, no changes in the tongue, no digestive disorders, no involvement of the nervous system and no enlargement of the spleen or liver. The reaction to the van den Bergh test varies. It is usually negative and occasionally delayed direct or indirect. Finally there is no physiologic response to adequate administration of liver extract beyond a transient reticulocytosis. There is an adequate supply of hemopoietic principle in the patient's liver, for extracts made from such a liver post mortem are just as effective as commercial liver extracts in the induction of remission in pernicious anemia. The bone marrow of these patients is deprived of hemopoietic principle in spite of an adequate supply in the liver. According to Israëls and Wilkinson these patients are unable to utilize the hemopoietic principle for any one or a combination of the following three reasons:

1 Failure to mobilize the hemopoietic principle from the tissue stores

2 Deficiency of some undiscovered factor

3 Utilization prevented by an inhibiting factor

Our case fits into this syndrome—achrestic anemia—very well and that diagnosis is highly probable. Final proof can be obtained only by extracting the patient's liver post mortem and showing that it contains an adequate supply of hemopoietic principle, and further demonstrating the absence of a lesion of the bone marrow which irritates the erythropoietic tissue resulting in increased megaloblastic activity, such as myeloid leukemia. The latter was ruled out by the absence of an enlarged spleen, the absence of immature granulocytes in the peripheral blood and the presence of normal leukoblastic tissue in the marrow.

Finally it is necessary to consider whether maturation of the megaloblast was disturbed or impeded by previous radiation therapy. The effects of radiation are shown classically by leukopenia with granulocytopenia, thrombocytopenia and dys-hemopoiesis. The red blood cells show but little evidence of regeneration. They are normal in size and show but little polychromasia or poikilocytosis. Hemorrhagic phenomena are prominent as well as are tendencies to necrosis of the mucous membranes. However, in the individual case not all the elements of the marrow need be injured simultaneously or equally. It is conceivable that a susceptible marrow might be injured by radiation therapy in a selective manner, causing dyshemopoiesis without dysmyelopoiesis but with depression of the megakaryocytic function, thus giving the picture found in our case. Rhoads and Barker<sup>2</sup> in a recent paper described cases of aplasia showing macrocytosis with alteration in the shape of the red blood cells varying from normal to profound. Whitby and Britton<sup>3</sup> as well as Lescher and Hubble<sup>4</sup> find a high color index. Some of these cases of aplasia therefore may be confused with hyperchromic macrocytic anemias because the precursor cells are produced normally but their maturation is interfered with.

The final diagnosis in this case therefore rests between this somewhat unorthodox conception of aplasia and the picture of achrestic anemia with which this case harmonizes so well. The weight of evidence, in our opinion, strongly favors achrestic anemia as described by Israëls and Wilkinson.

### CONFERENCES ON THERAPY

#### THE CHOICE OF DRUGS

NOTE—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital. The questions and discussions involve participation by members of the college staff, students and visitors.

DR HARRY GOLD It is a major accomplishment in drug therapy to be able to select wisely from a host of preparations of the same fundamental drug, each differing from the other in minor properties and in major claims. At least three factors constitute the basis for selection: (1) sound pharmacologic evidence, (2) clinical experience which meets high standards of scientific evidence and (3) cost. This morning we shall have time to consider choice in but few of the major groups of therapeutic agents. Dr Eggleston will consider choice among the digitalis preparations and the purine bases.

#### DIGITALIS, PURINE BASES

DR CARY EGGLESTON Today well standardized, reasonably uniform and trustworthy preparations of digitalis are commercially available in considerable numbers. Experience and pharmacologic studies seem to indicate that our choice of digitalis bodies should largely be limited to one for oral administration and one for intravenous administration, with immeasurably less emphasis on the problem of the choice, today at least, of one for parenteral administration other than intravenously.

Pharmacologic evidence shows quite definitely that there is no digitalis body for oral administration which is superior to digitalis leaf itself. Some of the partially purified extracts of digitalis are equally valuable, equally potent and equally useful, but for the most part they are considerably more costly to the patient, and so far as I am aware there is no satisfactory evidence to support the claim that they are in any way superior to digitalis leaf. An accurately standardized digitalis leaf, which is obtainable from any one of several manufacturers, is about all that is needed for oral administration. However, one should be certain of accurate standardization and that there are no false claims by the manufacturer and no slips from the straight and narrow path. We had an experience of a serious slip on the part of a manufacturer, which we feel was probably intentional and which resulted in considerable digitalis poisoning in the course of an experiment. We laid a little too much faith at the door of this manufacturer and accepted his statement as to the standardization of the digitalis. As a matter of fact, he was consciously supplying a preparation of digitalis that was more active than the standard of potency which he claimed and which he published on his labels. But any accurately standardized powdered leaf is likely to be thoroughly satisfactory for oral administration.

For intravenous administration there are a good many available digitalis extracts, most of which are more or less complex in composition. The most satisfactory in clinical tests appears to be not a digitalis extract but crystalline strophanthin-G or ouabain. This preparation has the advantages of solubility, small dose and relative uniformity, being a crystalline preparation.

Its dose is minute. The single dose should not exceed 0.5 mg. given to a patient who has not previously been digitalized within a brief period of time, say from ten days to two weeks. The complex digitalis extracts, among which are the proprietaries and specialties such as digifolin and digitan, may be used. I myself feel that very definite preference should be given to the crystalline strophanthin.

For intramuscular or subcutaneous injection there is, in my personal opinion, no satisfactory preparation because all the digitalis bodies which are in any way potent in their cardiac activities are more or less considerably irritant to the subcutaneous tissues. Furthermore, those which are sufficiently soluble in aqueous menstrua or in menstrua containing very small amounts of alcohol are generally composed of those portions of the digitalis glucosidal content which are rather untrustworthy in their absorption. Finally the digitalis bodies are for the most part not very well absorbed from the subcutaneous tissues irrespective of their composition. I have had the misfortune to witness rather serious necrosis of tissue and ulceration from the administration of digitalis bodies subcutaneously. Since, therefore, there is no particular advantage to the patient from the administration of digitalis bodies subcutaneously or intramuscularly, other than ouabain intramuscularly, in point of rapidity of action and certainty of absorption, it would seem to me to be wiser largely to limit our administration of digitalis either to the oral route or to the rectal route when the oral route is not available because of nausea or vomiting or similar factors, and the intravenous route in emergencies.

Digitalis is reasonably cheap if one uses preparations of the whole leaf which are official in the U. S. Pharmacopeia. It is often rather costly if one uses the proprietaries or specialties, which, as Dr. Gold has said, possess claims that are quite out of proportion to the merits of the preparation.

As to the xanthine derivatives I can speak with less confidence. It appears from evidence available as though most of the soluble xanthine derivatives were possessed of essentially the same actions, differing primarily in the intensity of the action and secondarily in their tendency to promote gastrointestinal irritation and to be ill tolerated by the gastrointestinal tract. It would be very nice were it possible to say that this preparation rather than one of the others was much less irritant to the gastrointestinal tract. There would not be much problem for choice. It has been my experience that choice must be directed to a considerable extent by the individual patient's ability to take the preparation. All the soluble xanthine derivatives are capable of irritating the gastrointestinal tract and producing digestive disturbances, even nausea and vomiting. Some seem to possess this disadvantageous feature to a lesser extent than others. The calcium double salt of theobromine appears to be one of these. In efficient doses aminophylline is often very well borne by the gastrointestinal tract. Theobromine with sodium salicylate is at times well borne. There are other occasions on which each of these is rejected by the gastrointestinal tract. Therefore we must, I think, make our selection by the effective but crude method of trial and error in any individual patient.

As for their potency, the theophylline derivatives appear to be more potent as diuretics than theobromine or than the other xanthine derivatives. That is about all I feel that we are justified in saying.

I should like to intrude on a subject that is coming up in a few minutes and while I am on my feet mention the question of morphine and other opium derivatives for hypodermic administration. It has been my observation and my experience that none of the substitutes for morphine possess any significant advantage over morphine itself for subcutaneous administration. Some are more potent, as for example dilaudid. They all have similar disadvantages in their capacity to produce nausea and vomiting and their high degree of toxicity in overdoses. I myself think that morphine, our old standby, in the majority of cases serves every desirable end in the opiate class for parenteral administration.

#### HORMONES OR ENDOCRINES

DR. EPHRAIM SHORR. Let us consider first the disturbances of the thyroid gland. The reasons for the early therapeutic success with the thyroid hormone lay in its oral efficacy. There has actually been little advance in its clinical application since 1892, when it was suggested that the fresh thyroid of a sheep fried slightly and served with currant jelly was an excellent mode of administration of the gland. Today we modify its administration only to this extent, that we defat and dry the gland and insist that the preparations adhere to definite standards of iodine content. It is not the purpose of this clinic to discuss the various indications for the use of thyroid substance and I will content myself with saying that, wherever there is an indication for thyroid therapy because of thyroid insufficiency uncorrectible by other means, the preparation of choice is any one of the dried thyroid substances which conform to the standards of the U. S. Pharmacopeia. Crystalline thyroxin is also available, but except for experimental purposes and for intravenous use when such seems unavoidable I do not think it has any place in general therapy. It is much less reliable when given orally than the desiccated thyroid preparations. A word of caution should be said with regard to the rapidity of thyroid replacement. In long-standing myxedema the readjustment to the higher level of cardiac activity should be brought about very slowly to avoid cardiac embarrassment.

It should be remembered that, unless thyroid insufficiency is due to atrophic changes in the gland, the gland is capable of elaborating its own thyroid hormone if given sufficient amounts of iodine. To permit this to occur it is merely necessary to administer relatively small amounts of iodine by means of any one of a number of iodine preparations. That used in this clinic is the syrup of hydriodic acid, which contains about 13 mg. of iodine in each cubic centimeter. One cc. a day is adequate. This preparation is more palatable and more convenient to take than compound solution of iodine (Lugol's solution). Furthermore, it is a personal gesture against the erroneous notion that the form of iodine contained in compound solution of iodine makes the latter superior to other iodine preparations.

The amount of thyroid hormone needed for complete replacement therapy in genuine myxedema is surprisingly small. It is indeed a rare case which will need more than 3 grains a day, and many do very well with less. The daily dose is best administered at one time and it serves no purpose and certainly causes inconveniences to divide the dose as is often done.

Quite distinct from the use of thyroid in replacement therapy is its use as a drug. We should be careful to separate clearly these two uses. There are undoubtedly those who function better when taking small amounts

of thyroid as a stimulant to activity I cannot, however, escape the impression that the thyroid hormone is used far too frequently for this purpose and that a more careful consideration of the factors underlying the fatigue for which it is given would reward both the physician and the patient with a more fundamental solution of the problem.

When one is dealing with the overactivity of the thyroid gland which occurs in Graves' disease, iodine is of course the most valuable therapeutic agent whatever mode of therapy, conservative or surgical, is chosen. Here again relatively small amounts of iodine (say 15 to 30 mg a day), appear to be adequate, although much larger amounts are usually given and with apparent safety. It is not my impression that, when small amounts of iodine fail to bring about the desired therapeutic effects, anything is ever gained by increasing greatly the amount of iodine administered.

In the treatment of the diseases of the adrenal cortex, of which Addison's disease alone is susceptible of endocrine therapy, two therapeutic agents are available. The first and cheapest of these is sodium chloride. In amounts of from 10 to 20 Gm a day, best by mouth when tolerated, parenterally if necessary, sodium chloride is often able to bring about considerable relief from the symptoms of Addison's disease. In some cases of a milder sort it alone may suffice. In more severe cases the preparations of the adrenal cortical hormone must be used in addition. There are available several such preparations, some more potent than others. A serious deterrent to their use is their costliness. This problem may be solved by the synthetic preparation of effective hormone which gives promise of being shortly available. An oral preparation adsorbed on charcoal is also available, but there is little evidence that it contains, in the amounts which can be given at present, enough of the hormone to serve for complete replacement in Addison's disease. It is not unlikely, however, that the hormone will eventually be given orally, since there is good evidence that it is effective by that route in animals.

Parathyroid insufficiencies can be dealt with very effectively by well standardized and commercially available extracts of the parathyroid gland. Treatment with this extract, the chemical constitution of which is still unknown, should be supplemented by the vitamins influencing calcium absorption and utilization, such as vitamin D, and by dietary measures to increase calcium intake and absorption. Remember that most of the cases of parathyroid insufficiency in adults occurring either spontaneously or after thyroidectomy can be effectively controlled without the use of parathyroid extract simply by means of a high calcium intake and vitamin therapy.

When we turn to the pituitary gland we find available the pituitary hormone pitressin, from the posterior lobe, the use of which in diabetes insipidus is extremely effective in bringing about relief from the marked diuresis. Pitressin is effective not only parenterally but also intranasally.

The state of the hormones of the anterior lobe of the pituitary is as yet still quite unsatisfactory. A variety of fractions, all with supposedly specific functions, have been prepared. Their chemical nature is quite uncertain and their therapeutic uses except in a few conditions which I shall discuss briefly are still largely dependent on animal rather than clinical investigation.

There is as yet little evidence for the gonadotropic activity of such hormones in women. In males they are useful to assist in the descent of the testis in cryptorchidism if the failure of descent is not due to anatomic defects. They are also of value in hypogonadism, in which they are capable of increasing the growth of the testis and secondarily of the penis. These gonadotropic principles of the anterior pituitary are, however, no more effective in these two conditions than the pregnancy urine extracts or the placental extracts, which apparently contain a similar principle or principles. These preparations are usually standardized in rat units. In cases of undescended testis it is customary to give from 200 to 500 rat units subcutaneously three times a week. It is generally agreed that a six months trial of such therapy should be given before resorting to surgery. It may well be that some of the cases that failed to respond with these customary doses may respond to higher doses of a thousand rat units three times a week or more. Avoid excessive gonadal development in youngsters, since such sexual precocity may bring on new problems.

In the impaired development of the gonads of the eunuchoid type it is generally necessary to employ large amounts of the hormone. As much as from 1,000 to 3,000 rat units three times a week may be necessary. Because of the protein content of these preparations, tolerance to these higher doses should be brought about slowly, otherwise unpleasant symptoms, such as local pain, general malaise and fever, may result. Gonadotropic hormones extracted from mare serum give promise of effectiveness, but not enough work has been done as yet to say more than this for the present.

The male hormone is now available in crystalline form as testosterone propionate. Two reliable preparations of this hormone are commercially available in 5, 10 and 25 mg amounts. The most definite indication for their use is the failure of sexual function which occurs after surgical castration. This is, of course, replacement therapy. Sexual function can be restored in such cases with the administration intramuscularly of 25 mg three times a week and in some cases 10 mg three times a week. The effects are obtained only as long as treatment is continued. This hormone can also be used to assist in the development of the external genitalia in male gonadal insufficiency. It also brings about increased sexual function in these cases. But it must be recognized that it is preferable to rely more on the gonadotropic hormones, which can induce testicular growth, so that the patient may then elaborate his own hormone. The two types of hormones may be used in conjunction with benefit in this condition.

Whether or not the male hormone will be of benefit in that rather vague state in the male which corresponds to the female menopause is a matter for further study. I have had no success in treating cases of psychic impotence. Strangely enough, the male hormone promises to be of some use in women, for there is evidence that it is effective in controlling menorrhagia.

When we turn to the female sex hormones we find a much more satisfactory situation. There are three naturally occurring and commercially available estrogenic hormones. These are the ketohydroxy, the dihydroxy and the trihydroxy estrin. Of these I have found only the ketohydroxy and the dihydroxy estrins therapeutically effective. These estrogenic hormones

like the thyroid hormone, are effective by mouth as well as when given intramuscularly. The intramuscular route is however the more efficient. The amounts necessary for complete replacement in the menopause vary from about 1,000 rat units three times a week to as much as 5,000 rat units daily. From this great difference from patient to patient it is apparent that each patient must be considered as an individual therapeutic problem from the aspect of dosage. I might suggest as an average dose 2,000 rat units three times a week. There are various methods of gaging the completeness of replacement therapy. That employed in this clinic is the development of a follicular vaginal smear. It is our practice to maintain replacement therapy for a period of from four to six weeks and then stop. Treatment is resumed when symptoms reappear. Patients should be warned about the possibility of pseudomenstrual bleeding on stopping treatment and reassured as to its significance. When these hormones are given by mouth, approximately twenty times the amount given intramuscularly are needed to produce an equivalent effect. In comparing the various commercial preparations as to effectiveness we have found that the rat units offer a more reliable index than the international units indicated on the labels. The estrogenic hormones are also useful in bringing about the development of secondary sex characters in states of primary amenorrhea. In such cases our procedure is to give enough hormone over the course of two weeks in each month to produce a follicular smear. This is usually followed by a pseudomenstruation and in time by the development of a typical feminine conformation.

There remains one other female sex hormone to be discussed, the hormone of the corpus luteum, which is commercially available as a synthetic preparation. Unfortunately its clinical use has not been extensive enough for us to know very much about what it may do. There is good reason to feel, from studies which have shown its abnormally low production in habitual abortion, that it may well be useful in maintaining pregnancy in such conditions. Its scarcity and costliness have usually resulted in its use in much too small amounts to be effective. To judge from the level of excretion, it is hardly likely that we can anticipate proper replacement with this hormone in amounts less than 10 mg a day.

I hope I have not sounded too pessimistic a note regarding many of the newer glandular preparations. I feel that extraordinarily rapid strides have been made during the past few years.

#### ARSENICAL AND BISMUTH PREPARATIONS

DR WALSH McDERMOTT. It takes so long for anything to happen to anybody with syphilis that the exact evaluation of any drug is a thing that must not be made too quickly. Arsphenamine has been out for only twenty-eight years and we still don't know all the things that it can do. In the clinic we use only six drugs: three trivalent arsenicals, one pentavalent arsenical, one heavy metal, potassium iodide. The three trivalent ones are arsphenamine, neoarsphenamine and mapharsen, mapharsen being used only extremely rarely in certain special cases. We believe arsphenamine to be the drug of choice in the treatment of early and latent syphilis. We feel that neoarsphenamine should not be used unless there is a definite indication for it. We use neoarsphenamine only in people who either have

cardiovascular syphilis or have had some reaction to arsphenamine. Before arsphenamine is given it must be neutralized. We give it by the gravity method, and that is cumbersome in private practice, in fact, that is what has limited its use. However, recently one company has put out a preparation of arsphenamine and gives along with it the exact amount of sodium hydroxide in individual ampules so that it is almost as easy to administer arsphenamine in private practice as it is to use neoarsphenamine, and the comparison between the two drugs from the point of view of therapy shows a high score on the side of arsphenamine. Mapharsen we use only in some patients who cannot take one of the other two drugs. We feel that mapharsen, which is an arsenoxide derivative, presumably the active principle of arsphenamine, may prove to be a very valuable drug. We know it will kill spirochetes. We do not know what it will do to the central nervous system or to the cardiac system, and it will take years of patient investigation before we shall be able to discover this. It does cause much fewer minor reactions and can be used for people who have trouble with the other drugs.

The reactions are important matters in the anti-syphilitic drugs. Between arsphenamine and neoarsphenamine there is practically no difference as far as the major reactions go, which we consider as jaundice, skin reactions and blood dyscrasias. The minor reactions, namely gastrointestinal upsets, headache and nitritoid reactions, are more common with arsphenamine. When you are administering these drugs it is very important to be sure that the patient has not eaten before taking it and does not eat for three hours thereafter. To some patients who have had skin eruptions we have been able to give mapharsen although they have very definite sensitivity to the other arsenicals, but that is not the case in all patients by any means. Also in people with jaundice after recovery we are able to go ahead with an arsenical drug, but there you have to consider each case separately. Tryparsamide is a pentavalent arsenical which has value only in disease of the central nervous system. It can be used in any case of syphilis of the central nervous system in which there is a lesion that would constitute a contraindication to one of the trivalent arsenicals. By that I mean it can be used in cases of combined central nervous and cardiovascular syphilis in full doses for the central nervous system syphilis without in any way damaging the status of the cardiovascular syphilis. When you are giving tryparsamide you must be sure to give some treatment with the other anti-syphilitic drugs to prevent progression of syphilitic lesions aside from the central nervous system disease. The dangers to the eye in tryparsamide treatment are grave, so that its administration in private practice is very hard unless you have a patient who can be seen in an eye clinic or by an eye specialist any time you wish.

We use bismuth compounds in place of mercury. There are fewer reactions after them locally, in the kidney, and in the mouth. We have those reactions from bismuth compounds but they are not so frequent or so pronounced as after mercury. Furthermore, all the available evidence seems to show that bismuth compounds are more effective therapeutically than mercury. We use an insoluble preparation of bismuth, the insoluble suspension of bismuth subsalicylate in oil. The reason we believe in an insoluble preparation is that

we wish to create a certain steady low level of bismuth in the blood, and it is cheapest. It is cheaper for the patient and cheaper for us. The soluble bismuth compounds have to be given two or three times a week, and you get a fluctuating level of bismuth in the blood. The minor reactions are the things that are more common. We classify them euphemistically as minor, but they are not minor to the patient. Nausea and vomiting may be minor to us, but to the patient on a sixty-eighth street bus it is major and so you have to be careful about such things, but you can by changing the dosage and sometimes the drug do a great deal. The dose we use of arsphenamine is 0.4 Gm in a man and 0.3 Gm in a woman, of neoarsphenamine it is 0.6 Gm in a man and 0.45 Gm in a woman, of mapharsen it is much less, 60 mg in a man. The tryparsamide dosage is way off from the others, being 3 Gm for a normal dose.

We have read in the papers recently about the accident resulting from improper neutralization and that is something those of us who handle these drugs wake up in the night worrying about. We take the utmost precautions here, keeping the two drugs in different parts of the clinic, but even so we keep in mind the necessity of checking the procedure at every point.

#### LIVER AND IRON PREPARATIONS

DR PAUL REZNIKOFF: If a patient needs liver we give him liver, and if a patient needs iron we give him iron, not a mixture of the two. However it is not quite as simple as that. Most patients can take iron in almost any form, either reduced iron, ferric and ammonium citrate, or ferrous sulfate, but we have been using ferrous sulfate because it is cheaper, it can be given in effective dosage without gastrointestinal disturbance in most patients, and actually it is administered in smaller doses because it is probably more easily absorbed. The ordinary type of ferrous sulfate we use here comes in tablets. Each of these tablets contains about 60 mg of iron. Originally it was thought it was necessary to give to an iron-deficient patient 1 Gm of iron a day. I think that is more than is necessary. We think now an adult patient with iron deficiency, anemia, can get along perfectly well with 0.5 Gm a day. That would mean about nine of these tablets or three tablets three times a day, and because iron may upset the gastrointestinal tract we give it after meals.

There is another type of ferrous sulfate which is even more easily tolerated, and that is the elixir. A dose of 4 cc contains 0.12 Gm of ferrous sulfate and you must remember that ferrous sulfate is only one-third iron. The other types of iron are effective but have to be given in large amounts as a rule. Iron and ammonium citrate has to be given in daily doses of about 6 Gm and reduced iron of about 1 to 3 Gm to have a comparable effect. There are about 500 iron products that have been on the market, and I don't think it makes very much difference which one is used. We have in this hospital experimented with the ferrous gluconate. Our original idea was to see if we could get a parenteral type, but it is not practical to give iron parenterally because iron is a substance that has to be given daily for a long period, at least a month in most cases, and after patients have been injected daily for a month, and it does not make much difference how much care is taken in the process, they will have a great many marks which make it unpleasant. Therefore I think we might say that today we use ferrous

sulfate in some type or other, three doses daily after meals, so that the adult patient is receiving a total of at least 0.5 Gm of iron as iron a day. One way of diminishing gastrointestinal disturbances with iron is to start with a small dose and increase daily to approach an optimum.

Liver extracts have recently been standardized on the basis of a unit system. Those working with parenteral liver extract—the most effective way to treat a patient—felt the need of a dosage in units as in the case of insulin. They spent a long time trying to develop a unit. They now have a unit, which is defined as the amount of liver extract daily which in at least three patients with pernicious anemia under standard conditions will produce a standard reticulocyte response. Patients differ and the unitage is made to depend on the particular patients that have been studied. Since the strength of the unit is variable, we must give very large doses and use the effects in our patients as our guide. Therefore our policy is to do this. A patient with a relapse is given a large dose of liver extract, from 15 to 30 units a day for four consecutive days. Then the patient continues to receive this dose two or three times a week, that is, after the reticulocytes have returned to normal and the red cell count has begun

#### Wholesale Druggists' Prices, 1938

Proprietary (per Ounce)		Nonproprietary (per Ounce)	
Phenacetin	\$0.62	Acetophenetiden	\$0.16
Aspirin Bayer	0.75	Acetylsalicylic acid	0.13
Veronal	3.00	Barbital	0.56
Atophan	2.75	Cinchophen	0.35
Duotal	1.10	Guaiacol carbonate	0.30
Urotropin	0.25	Methenamine	0.15
Tolysin	2.00	Neocinchophen	1.04
Luminal	6.90	Phenobarbital	0.57
Trional	1.90	Sulfonethy imethane	0.70
Sulfonal	1.70	Sulfonmethane	0.55
Diuretin	1.85	Theobromine with sodium	
Aristol	1.80	salicylate	0.25
		Thymol iodide	0.45

to rise. By the method of trial and error we determine the maintenance dose which will keep the patient at a normal red blood cell count, 4.5 million for women and 5 million for men.

One other thing which I have time to call to your attention is this. While it is more convenient to give fewer cubic centimeters per dose, liver extract loses potency in the process of refining. For example, the 10 cc product we used to have at the New York Hospital, derived from 50 Gm of fresh liver, was as potent as the concentrated 3 cc or 1 cc derived from 100 Gm. However, to insure adequate dosage we give our patients more than the estimated minimum requirement, since we know of no deleterious effects of very large doses and since the excess potent fraction is not destroyed or excreted but is stored.

DR GOLD: Mr. Clarke who is head of the hospital pharmacy has had to grapple with many practical problems in the selection of drugs, and he will tell us of some of his experiences in this connection.

#### COST OF DRUGS

MR DONALD A. CLARKE: The two considerations which play an important part in our selection of preparations in the hospital pharmacy are price and quality. I have assembled a few of the figures on costs which help to give some idea as to where these matters stand with respect to some of the more common medicines that are prescribed.

In this table are listed the comparative costs of some of the proprietary and nonproprietary preparations of the same drug. The prices were obtained from one of the outstanding wholesale drug supply houses in New York City. Please note how much we pay for a protective name. For example, veronal costs five times as much as the same drug under the U S P official name barbital, luminal, twelve times as much as the same drug under the U S P official name phenobarbital. Among other barbituric acid compounds similar differences in price are encountered. Interesting relations may be seen by using a dose of 0.1 Gm of soluble phenobarbital as the basis for comparison. This is the U S P preparation and this dose costs the patient 0.2 cent. A similar dose of amytal sodium costs more than ten times as much, the same for oral sodium, of alurate sodium more than twelve times as much, of pentobarbital sodium fifteen times as much and of seconal about twenty times as much. I believe that these doses are fairly comparable. There are differences in the actions of these compounds, but there may well be numerous instances in which the very costly preparations are prescribed when all the therapeutic effects that are necessary can be obtained from the much cheaper phenobarbital.

Theobromine with sodium salicylate is a U S P preparation which is relatively inexpensive, but if you fail to write the official name and instead order it under the protected name, diuretin, this material will cost your patient more than seven times as much. These are matters to which attention has been called repeatedly. A recent publication called "The Costs of Medicine" by Rorem and Fischelis, under the auspices of the Committee on the Costs of Medical Care, gives an extensive discussion of this subject.

The digitalis preparations also provide useful data with regard to cost. The patient pays 0.6 cent for 1 cat unit (1 cc) of the U S P tincture of digitalis but less than one-half as much (0.3 cent) for a similar dose (1 cat unit) of a good standardized digitalis leaf in tablets. Compare the latter with the proprietary preparation digitan (Merck), digitoline (Ciba) and digalen (Hoffman-La Roche) in ampules. These cost, for the same amount of the drug, namely 1 cat unit, fifty, fifty and thirty times respectively as much as the digitalis leaf.

Dr Eggleston referred to morphine and its substitutes and stated that the substitutes appear to afford no special advantages over morphine itself. In the light of this, the difference in the cost of morphine and some of its substitutes becomes more important. A dose of morphine for hypodermic injection in the form of an ampule of pantopon costs about ten times as much as a similar dose of morphine sulfate, and in the form of an oral tablet it costs about six times as much as an oral tablet of morphine sulfate. A hypodermic dose of dilaudid ( $\frac{1}{16}$  grain tablet) also costs about six times as much as a therapeutically equivalent dose of morphine (one-fourth grain tablet).

Among liver preparations for the treatment of pernicious anemia, wide differences exist in the cost of comparable doses. For example, a daily dose of one of the concentrated parenteral preparations costs only 4 cents, whereas a daily dose of one of the preparations for oral administration costs as much as 40 cents. However, the cost to the patient may be less in the latter case than in the former, because in the one instance an injection is necessary and this may require

the daily services of a physician, whereas in the case of the oral material such frequent attention of the physician is not necessary.

In the field of the glandular products the point that appears necessary to emphasize is the very high cost of adequate doses of potent materials. Several examples of approximate costs of treatment may be cited. The cost of adrenal cortical substance is prohibitive. One of the patients in the clinic who requires 18 cc daily for replacement in Addison's disease is receiving a dose of a preparation costing about \$8 a day. The gonadotropic hormone preparations are also extremely expensive. The preparation known as follutein costs about \$12 for 5,000 rat units, and a course of treatment often calls for 500 units three times a week, as Dr Shorr has indicated. Antutrin-S is even more expensive, \$4 per thousand rat units. The male sex hormone, the crystalline testosterone propionate, costs \$12 for three ampules of 25 mg each and, as you have heard, as much as 25 mg three times a week is sometimes necessary in replacement therapy. The female sex hormones amniotin and theelin cost about \$1 per average dose of 2,000 rat units, or about \$3 a week in a course of treatment which may run over a period of several weeks. The synthetic preparation of the corpus luteum which is now available costs \$7.50 for 10 mg. You can readily calculate what the total cost to the patient will be if, as Dr Shorr suggested, a daily dose of 10 mg is necessary for replacement over a period of months of pregnancy.

DR GOLD: I am afraid we have run over the hour, and unfortunately have no time for questions. If somebody feels an irrepressible urge to put a question, however, it may be possible to have it answered.

STUDENT: How can a physician practicing outside secure the digitalis put out by the New York Heart Association?

DR EGGLESTON: He cannot. Those preparations are limited to use by clinics which are members of the Heart Association. However, there are preparations manufactured on the same general principles which have proved trustworthy over periods of years.

STUDENT: Would you tell us what preparations those are?

DR EGGLESTON: There are several. One is the preparation made by Lederle, a powdered digitalis leaf which has stood the test of experience over a period of years and is alleged to be made according to the requirements of the New York Heart Association. Another similar preparation is made by Schieffelin & Co.

STUDENT: Do you use the same dosage with these?

DR EGGLESTON: Yes, the same dosage.

DR WALTER MODELL: What about the relative cost of bulk ether as compared with that of small cans of ether?

DR MCKEEN CATTELL: Certainly you can reduce the cost of ether for anesthesia to about one fourth by using bulk ether in 27 pound drums instead of the quarter pound cans. It used to be thought that ether deteriorates quickly, but the work which has been going on in our laboratory shows that ether does not deteriorate even during several weeks after the metal container has been opened repeatedly. There are several large hospitals which are now using bulk ether for anesthesia entirely satisfactorily.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEITCH Secretary

**EPINEPHRINE** (See New and Nonofficial Remedies, 1938, p 230)

**EPINEPHRINE U S P-UPJOHN**—Marketed in vials containing 0.065 Gm (1 grain)

Manufactured by the Upjohn Company Kalamazoo Mich  
*Solution Epinephrine 1 1000 Upjohn* Each cubic centimeter contains epinephrine 1.0 mg sodium chloride 7.0 mg sulfur dioxide (as sulfurous acid) not more than 0.6 mg chlorobutanol not more than 5.0 mg dissolved in distilled water saturated with carbon dioxide Marketed in packages of 1 cc ampules and 10 cc vial

**SCOPOLAMINE HYDROBROMIDE** (See New and Nonofficial Remedies, 1938, p 377)

**SCOPOLAMINE HYDROBROMIDE-MERCK**—A brand of scopolamine hydrobromide-U S P

Manufactured by Merck & Co Inc Rahway N J  
*Scopolamine Hydrobromide Crystals Merck* Marketed in vials of 1.5 and 15 grains  
*Scopolamine Hydrobromide Powder Merck* Marketed in vials of 1.5 and 15 grains

**CAFFEINE WITH SODIUM BENZOATE** (See New and Nonofficial Remedies 1938 p 156)

*Ampuls Caffeine with Sodium Benzoate 2 cc* An aqueous solution containing in each 2 cc caffeine with sodium benzoate U S P 0.5 Gm (7½ grains)

Prepared by The Maltbie Chemical Co Newark N J

**THIAMIN CHLORIDE** (See THE JOURNAL, July 16, 1938, and the Revised Supplement to New and Nonofficial Remedies, 1938, p 23)

**Thiamin Chloride-Abbott**—A brand of thiamin chloride-N R

Manufactured by Abbott Laboratories North Chicago No U S patent or trademark.  
*Tablets Thiamin Chloride Abbott 0.33 mg* Each tablet contains 100 international units of thiamin chloride  
*Tablets Thiamin Chloride Abbott 1.0 mg* Each tablet contains 300 international units of thiamin chloride  
*Tablets Thiamin Chloride Abbott 3.3 mg* Each tablet contains 1000 international units of thiamin chloride  
*Ampoules Solution Thiamin Chloride Abbott 0.66 mg* Each ampule contains 2000 international units of thiamin chloride  
*Ampoules Solution Thiamin Chloride 1.0 mg 1 cc* Each ampule contains 300 international units of thiamin chloride  
*Ampoules Solution Thiamin Chloride 10.0 mg 1 cc* Each ampule contains 3000 international units of thiamin chloride

**SOLUTION OF FORMALDEHYDE** (See New and Nonofficial Remedies, 1938, p 248)

**SOLUTION OF FORMALDEHYDE-MERCK**—A brand of solution of formaldehyde U S P

Manufactured by Merck & Co Inc Rahway N J

**BISMUTH SUBSALICYLATE** (See New and Nonofficial Remedies, 1938, p 142)

*Bismuth Subsalicylate in Oil Suspension* A suspension of bismuth subsalicylate in peanut oil each cubic centimeter containing 2 grains (0.13 Gm) of bismuth subsalicylate U S P (equivalent to 75 mg of Bi metal) and 0.03 Gm (3 per cent) of chlorobutanol Marketed in bottles containing 30 cc 60 cc and 100 cc  
Prepared by the Diarsenol Company Inc Buffalo N Y No U S patent or trademark

**PROCAINE HYDROCHLORIDE** (See New and Nonofficial Remedies 1938, p 74)

**PROCAINE HYDROCHLORIDE-THE UPJOHN CO**—A brand of procaine hydrochloride-U S P

Manufactured by The Upjohn Co Kalamazoo Mich No U S patent or trademark.  
*Ampoule Solution Procaine Hydrochloride ½ cc with Epinephrine 5 cc* Each cubic centimeter contains procaine hydrochloride U S P 0.005 Gm epinephrine 0.05 mg sodium bisulfite 1.6 mg benzoic acid 0.06 mg sodium chloride 8.5 mg normal hydrochloric acid 0.0007 cc dissolved in distilled water and saturated with carbon dioxide

*Ampoule Solution Procaine Hydrochloride 2% with 1 epinephrine 1 cc* Each cubic centimeter contains procaine hydrochloride, U S P 0.02 Gm epinephrine 0.05 mg sodium bisulfite 2.6 mg benzoic acid 0.3 mg sodium chloride 8.3 mg normal hydrochloric acid 0.0016 cc dissolved in distilled water and saturated with carbon dioxide

*Ampoule Solution Procaine Hydrochloride 2% with 1 epinephrine 3 cc* Each cubic centimeter contains procaine hydrochloride U S P 0.02 Gm epinephrine 0.05 mg sodium bisulfite 2.6 mg benzoic acid 0.3 mg sodium chloride 8.3 mg normal hydrochloric acid 0.0016 cc dissolved in distilled water and saturated with carbon dioxide

*Solution Procaine Hydrochloride 1% with 1 epinephrine 30 cc Vials* Each cubic centimeter contains procaine hydrochloride U S P 0.01 Gm, epinephrine 0.02 mg sodium bisulfite 2.1 mg benzoic acid 0.2 mg sodium chloride 8.4 mg normal hydrochloric acid 0.00125 cc chlorobutanol not more than 5 mg dissolved in distilled water and saturated with carbon dioxide

*Solution Procaine Hydrochloride 2% with Epinephrine 30 cc Vials* Each cubic centimeter contains procaine hydrochloride U S P 0.02 Gm epinephrine 0.05 mg sodium bisulfite 2.6 mg benzoic acid 0.3 mg sodium chloride 8.3 mg normal hydrochloric acid 0.0016 cc chlorobutanol not more than 5 mg dissolved in distilled water and saturated with carbon dioxide

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C BING Secretary

#### CELLU BRAND RED CHERRY JUICE

*Distributor*—Chicago Dietetic Supply House, Inc, Chicago

*Description*—Canned red cherry juice packed without added sugar

*Manufacture*—Selected ripe red cherries are picked washed, chilled by immersion in cold water and macerated. The semi-liquid material is run through a hydraulic press. The juice is then pasteurized cooled, filled by the so-called vacuum process into enamel-lined cans, sealed under vacuum and processed

*Analysis* (submitted by distributor)—Moisture 87.7%, total solids 12.3%, ash 0.3%, fat (ether extract) 0.6%, protein (N × 6.25) 0.5% crude fiber none, carbohydrate, (by difference) 10.9% invert sugar 9.0%, sucrose 0.1%

*Calories*—0.5 per gram, 14 per ounce

#### MRS PALEY'S BABY FOOD—STRAINED ASPARAGUS

*Manufacturer*—Paley Sachs Food Company, Houston, Texas

*Description*—Canned, sieved asparagus, slightly seasoned with salt

*Manufacture*—Selected canned white asparagus is sieved, filled into glass jars, vacuum sealed and heat processed

*Analysis* (submitted by manufacturer)—Moisture 93.3%, total solids 6.7%, ash 0.8%, fat (ether extract) 0.4%, protein (N × 6.25) 2.2%, reducing sugars as dextrose 12%, sucrose 0.4%, crude fiber 0.7%, total carbohydrates other than crude fiber (by difference) 2.6%, calcium (Ca) 0.015%, phosphorus (P) 0.0037%, iron (Fe) 0.0035%

*Calories*—0.2 per gram, 6 per ounce

#### CELLU BRAND APRICOT JUICE

*Distributor*—Chicago Dietetic Supply House, Inc, Chicago

*Description*—Canned apricot juice packed without added sugar

*Manufacture*—Selected, tree-ripened apricots are sprayed with water, sorted pitted preheated and pressed through coarse mesh cloth. The juice which contains some of the insoluble solids of the pulp, is filled into cans and processed without preheating in special vacuum sealing machines. No toxic spray materials are used on the growing fruit

*Analysis* (submitted by distributor)—Moisture 88.4%, total solids 11.6%, ash 0.5%, fat (ether extract) 0.4%, protein (N × 6.25) 0.5%, crude fiber 0.04%, carbohydrates other than crude fiber (by difference) 10.2%, invert sugar 4.7%, sucrose 4.2%

*Calories*—0.5 per gram 14 per ounce

## DIAGNOSIS OF GONORRHEA BY CULTURE

Ordinarily the diagnosis of acute gonorrhea presents few great difficulties. In the chronic forms, however, and when the infection is located extragenitally, prompt and accurate diagnosis is sometimes not so easy. Early and accurate identification is important not only from the point of view of treatment but also in the control of the disease.

One of the most satisfactory additions to diagnostic methods is the use of culture mediums in the determination of the presence of gonococci in chronic or atypical lesions. Recent experience with this procedure seems to indicate that the best method of culturing the gonococcus so far devised is by the use of a chocolate agar incubated in an containing 8 per cent carbon dioxide as described by McLeod and his co-workers<sup>1</sup> with or without the help of the oxydase reaction or slight modifications of this technic. Using a variation of McLeod's procedure with a chocolate agar made from a Douglas agar base and the incubation of duplicate cultures at 34 and 37 C in 10 per cent carbon dioxide, Carpenter and his colleagues<sup>2</sup> examined the cervix and urethra of 245 adult female patients, making also smears in each case. From both methods eighty, or 32.7 per cent, proved to be positive. In all, 843 cultures with smears were submitted to the laboratory, of which 223 were positive by either the cultural or the smear method. Of the 223 bacteriologic examinations reported as positive the cultural method revealed gonococci in 205, or 91.9 per cent, of the specimens, while the organism was found in smears in only 107, or 48 per cent. In eighteen instances positive smears were obtained when cultures were negative. The use of the two methods simultaneously, therefore, increases the

positive diagnoses enormously over the use of the smear method alone, and not inconsiderably over the cultural method alone. These investigators concluded, therefore, that both methods should always be used. Stout and Todd<sup>3</sup> followed the McLeod procedure in the examination of ninety-three cultures from various sources. They obtained twenty-two positive cultures, or 23.6 per cent. In the analysis of their results they found the cultural method superior to the smear in twelve, or 15.6 per cent, but failed to obtain growth in thirteen cases in which there were gram-negative diplococci present in the smears. Jacobsen and her co-workers<sup>4</sup> attempted the isolation of the gonococcus in 100 cases of chronic female gonorrhea. Plated culture mediums were directly streaked from the urethra and the endocervix with sterile cotton applicators and within two hours were placed in an incubator kept between 35 and 37.5 C. Most of the cultures were incubated in lots of from six to eight in air-tight Novy jars in which from 8 to 10 per cent carbon dioxide was produced by mixing sulfuric acid with a solution of sodium bicarbonate. The routine mediums used were plain blood agar, chocolate agar, amniotic fluid agar, testicular agar, chocolate agar with a Douglas agar base, and ascitic fluid agar with a Douglas agar base. They also concluded that Douglas agar with heated blood is the medium of choice and that the presence of carbon dioxide in the incubator atmosphere is more important than the presence of moisture for the primary isolation of gonococci by culture. Their analysis also indicated that cultures are superior to direct smears. In addition they felt that the gonococcus fixation tests were superior to either cultures or direct smears. Reitzel and Kohl<sup>5</sup> have also been successful in culturing gonococci from various lesions either on hormone brain broth or on brain heart infusion with the addition of ascitic fluid. Similar successful reports have been appearing with increasing frequency in the foreign literature.

Although there is nothing new in the attempt to culture gonococci from the tissues, recent methods have improved the possibilities. At present the necessary technic and equipment restrict the application of cultural methods of diagnosis, but still further simplification may well increase its applicability. Finally it must be emphasized that the cultural examination for gonococci is not necessary when such organisms can be readily identified by smear but that in the more difficult cases both smear and culture and possibly complement fixation tests enormously increase the number of cases of gonococcal infections properly identified.

## DERMATOMYOSITIS

Dermatomyositis is rare in appearance and mysterious in origin. So closely does it resemble other conditions in some respects that doubt has been expressed that it is an entity. Dowling and Freudenthal,<sup>1</sup> after citing three cases, summarize the clinical picture of dermatomyositis. Occasional prodromes appear as patches of erythema or Raynaud-like symptoms, during which the diagnosis is impossible. Usually the condition begins with erythema and swelling of the face and eyelids, sometimes extending to other regions. This phase may last for months but is succeeded by more persistent cutaneous changes resembling lupus erythematosus and spreading from the face to the neck, thorax, shoulders, arms and elsewhere. In severe cases early and extensive muscular weakness occurs and usually acute swelling and pain. An intermittent fever is usually, although not always, found at this stage. Histologically the epidermis is thinned with diminished or absent rete pegs, sclerotic connective tissue and diminished elastic fibers in the sclerotic areas.

In a case of dermatomyositis recently reported by Hendry and Anderson,<sup>2</sup> the symptoms began with a roughness or chapping of the hands followed by itching in the back of the neck and flexor aspects of the elbows and knees and swelling of the hands and feet. Later there was severe weakness, stiffness of the shoulders and elbows and difficulty in swallowing, and the skin had a violet blue tint. The legs were weak but obvious wasting was not apparent. Microscopic examination of some muscle and skin removed by biopsy revealed the interstitial tissue of the muscle extensively infiltrated by mononuclear cells in relatively large foci, comprising a small portion of plasma cells. The adjacent muscle fibers were more or less atrophic. Changes in the skin and fat were characterized by a scanty round cell perivascular infiltration. In another case reported at the same time by Sheldon and his collaborators<sup>3</sup> weakness, edema and changes in the voice were again prominent symptoms. The general color of the patient was pale, but over the bridge of the nose, both eyelids and the upper parts of the cheeks was a swollen area covered with a bright red erythema. This patient died. Portions of voluntary muscle from various parts of the body showed an intense edema with some localized increase of fibrosis of the areolar tissues normally lying between the muscle bundles. Accompanying this edema was a degenerative process of the muscle fibers themselves, indicated by fragmentation and a hydropic type of degeneration of the muscle fibers. The process elsewhere in the body was described in short as a generalized reticulo-endotheliosis, although the changes in the

muscles were apparently due to inflammation and degeneration, few endothelial cells being found. Sheldon and his colleagues therefore suggest that the basis of dermatomyositis is a reaction of the reticulo-endothelial system, usually local but occasionally generalized, and due to some cause as yet unknown.

In a case reported by Lane,<sup>4</sup> the close similarity between dermatomyositis and lupus erythematosus disseminatus is brought out. The clinical course in this case, however, differed from lupus in that the pain and tenderness were in the muscles and tendons rather than in the joints. Without exception the redness, edema, fever and leukopenia could easily have been mistaken for that of lupus erythematosus. Lane feels, furthermore, that these diseases may be closely related etiologically. Although satisfactory progress is being made in the understanding of the clinical manifestations and pathologic anatomy of dermatomyositis, the etiologic factors remain elusive.

## ORAL POLLEN PREPARATIONS

Early last year THE JOURNAL published a statement from the Chicago Society of Allergy in reference to oral pollen preparations placed on the market by some pharmaceutical houses. The Chicago allergists urged others to sound a note of warning not only because of the probable numerous disappointments which might occur following the use of oral pollen preparations but also because of the possible dangers inherent in any new and unproved method of treatment. A year previously THE JOURNAL, in *Queries and Minor Notes*, emphasized that self-administered therapy of this type is likely to lead to disappointments. Elsewhere in this issue appears a new communication from the Chicago Society of Allergy.<sup>1</sup> The society is to be commended for its stand against the exploitation of a product for oral administration in the treatment of hay fever which may be not only not beneficial but a decided economic loss to the patient. The difficulty of regulating dosage because of the difference in rate of absorption from the gastrointestinal tract alone is a serious objection to this mode of therapy. It will require considerable evidence to show by passive transfer work that pollen is absorbed in the doses intended. At present oral pollen preparations for the treatment of hay fever are apparently being promoted by Allergy Research Laboratories, Phoenix, Ariz., Pollen Laboratories, Phoenix, Ariz., Hollister-Stier Laboratories, Spokane, Wash., G. H. Sherman Company, Detroit and Eli Lilly and Company, Indianapolis. The Council on Pharmacy and Chemistry of the American Medical Association has accepted no pollen preparation proposed for oral administration.

THE WAGNER BILL AND GENERAL HOSPITALS

Section 1201 of the Wagner bill, S 1620, authorizes the appropriation in successive years of eight, fifty and one hundred million dollars, respectively, for the construction and improvement of general hospitals. Under section 1203 (a) (1), financial participation by the states is required. Naturally the extent of this participation will vary from state to state. Assuming, however, that the contributions of the federal government will be on a fifty-fifty basis,<sup>1</sup> there will be available for the construction and improvement of government-owned general hospitals \$16,000,000 in the fiscal year ending June 30, 1940, \$100,000,000 in 1941 and \$200,000,000 in 1942. Taking \$4,000 as the average cost per bed of general hospitals - this bill would make

Average rate of increase in number of beds in general hospitals and estimate of increase proposed in Wagner bill

provision for the addition of 4,000 general hospital beds in 1940, 25,000 general hospital beds in 1941 and 50,000 general hospital beds in 1942. These figures relate only to government-owned hospitals and do not include such enterprises, public or private, as may be undertaken without the stimulus of a federal subsidy. From the accompanying chart it will be seen that over the eleven year period 1928-1938 inclusive the average rate of increase in the number of beds in general hospitals was 1.9 per cent. The increases in number that are proposed in the Wagner bill amount to a total of 79,000 beds, 16.2 per cent, in three years, or an average rate of increase of 5.4 per cent. In 1938 the general hospitals of the country were filled to 68.9 per cent of their capacity, 31.1 per cent of the beds were unused. Wherein lies the justification of the proposal to multiply threefold the normal increase of hospital facilities?

DISTINGUISHED SERVICE MEDAL

The second medal to be awarded for distinguished service to scientific medicine will be presented at the opening general meeting at the St. Louis session on May 16. The recipient of this medal is chosen by a process of selection which insures choice of an outstanding physician and scientist. Any physician who wishes to nominate a candidate for the Distinguished Service Medal may send his nomination to the chairman of the committee, Dr. E. L. Henderson of Louisville, Ky. This committee sends five nominations to the Board of Trustees of the American Medical Association, which then selects three names from the five. The three names are presented to the House of Delegates at the opening of the meeting, which will on this occasion be Monday morning, May 15. The House of Delegates votes immediately and the recipient of the honor is presented with the medal on the following night. Last year the first medal was awarded to Dr. Rudolph Matas, distinguished surgeon of New Orleans. Other candidates nominated to the House of Delegates included Dr. Simon Flexner and Dr. Ludvig Hektoen. By this award the American Medical Association indicates its recognition of scientific advancement as one of the main functions of organized medicine. Fellows of the Association can cooperate by sending to the chairman of the committee the names of those whom they believe to be entitled to such an honor, together with a record of their services to science.

FLORIDA TELEPHONE DIRECTORIES

The users of Florida telephone directories published by the Southern Bell Telegraph and Telephone Company may now know whether a person listed therein as a doctor is a doctor of medicine, an osteopath, chiropractor or naturopath, or a practitioner of any other method of healing. In the alphabetical list in the directory, after each name of a doctor of medicine appears the suffix "Dr. Phys.," and a similarly identifying suffix after the name of each cult practitioner listed. The classified section in the directory is arranged similarly to differentiate between the practitioners of the different methods of healing authorized by law in Florida. This change in the method of listing practitioners in the telephone directories followed the enactment of a law that requires every practitioner of the healing art to place and keep in a conspicuous place at each entrance of his office or usual place of business words or abbreviations denoting the particular kind or branch of healing in which he is lawfully entitled to engage. This law was considered as having established as a matter of public policy the desirability of public disclosure of the type of practice in which each practitioner engages. The telephone company, to further the public policy, and at the request of the medical profession of Florida, revised its methods of listing practitioners in its directories, a procedure it had theretofore hesitated to undertake. The Florida Medical Association with the cooperation of the telephone company has thus succeeded in eliminating a potential source of misinformation and danger for those who resort to telephone directories to ascertain the method of practice pursued by any practitioner.

# ORGANIZATION SECTION

## CANADIAN EXPERIMENTS IN MEDICAL ECONOMICS

T. C. ROUTLEY, M.D., LL.D., F.R.C.P.(C)

General Secretary of the Canadian Medical Association  
TORONTO

For a period of two thousand years and more medicine has been engaged in building its structure. Generation after generation has given to the world men of science, men of learning, men of courage, who have been willing to forget self to sacrifice and to die if necessary in order that the ever accumulating knowledge of health and disease might more deeply penetrate the unknown, looking to the day when speculation regarding the ills of man would be replaced by complete understanding.

During this long period medicine has been on the march, sometimes marking time, sometimes standing easy, but in the main marching forward never backward. There is none among us who will say that victory has been won on all fronts. On the contrary, we will readily admit that what has been accomplished is but a prelude to what lies before. Nevertheless, accomplishments there have been, and multitudes of people scattered throughout the world are living testimonials to scientific achievements in the field of endeavor of which the members of our profession are disciples.

As we contemplate what has taken place in the development of our scientific knowledge, we should also direct our attention to what has concomitantly taken place with regard to our place in the social universe.

There was a day not so long ago when our knowledge and our dispensation of it were neither called in question nor disputed. "The doctor says so" was all sufficient. The doctor's public confidently and complacently accepted his advice and followed his instructions. The doctor was satisfied to have it so. He gave no thought to the situation's ever being subject to change. Indeed, many doctors will neither admit nor recognize that changes are taking place in the public mind. Such doctors, however, are like the foolish virgins, their lamps are without oil. Good and true servants though they be, they are proceeding blindly and if left to flounder by themselves will be wrecked on the reefs of change which they can not or will not see.

What is it that has happened?

What is all this talk about change in the public mind?

Who are the busybody bunglers in our own ranks who continue to stir up trouble for the profession?

Why can we not carry on as our forefathers did and their forefathers before them?

Leave us alone and let us practice scientific medicine in our own way.

But, alas, we cannot stop our fellow men from thinking and speaking and acting, any more than we can turn back a raging prairie fire. Perhaps, if one may continue the analogy, we should plow some furrows and burn a few patches here and there, so that the prairie fire may be brought under control. Perhaps too the burned-over ground might bring forth results to satisfy all who dwell thereon. In any event we must deal with situa-

tions as we find them and not with academic discussions. The facts are before us.

Great masses of people of high and of low estate, and in increasing numbers, are thinking and saying that they know better than do the doctors how medicine should be practiced. So far as one knows they do not question the doctor's willingness to treat rich and poor alike, but they do question his ability to determine the modus operandi by which his professional skill shall be made available, particularly to that great middle class of the population commonly described as average and low wage earners. From all this turmoil there has emerged not a new science but a most lively and active interest in a branch of our profession which we describe as medical economics.

Medical economics has been defined as "the science that investigates the conditions and laws affecting the production, distribution, consumption and cost of the various types and kinds of medical services that promote and preserve the health of the people." If we accept this definition as one which broadly covers the subject, it will be seen that the medical profession has every right and indeed every obligation to investigate and define the conditions and laws which have to do with the various types of medical service to which the public is entitled, looking to the preservation of the health of the people at the optimum level.

Speaking for myself, I am not willing to admit for one moment that the medical profession as a body is incompetent to determine how best the public shall be served. On the contrary, it is my firm belief that, given the opportunity to act in a corporate manner, the medical profession is equal to any task which properly comes under its purview. I say advisedly that we are equal to the task, but I think that one should be just as emphatic in saying that we are equal only so far as we are willing to assume the task.

What is the task?

Briefly put, I think it is this. To provide adequate medical care for all the people at a price which is fair to all the people, including those who render the service. That is our task.

Is it? Well, if it is not our task it certainly belongs to somebody, because the public has a right to expect and demand medical services at a price within its competence to pay, and if we should prove ourselves unwilling or unable to organize on a basis to meet the public's proper demands we deserve to become enmeshed in plans not of our making or choosing. But, may I repeat, the members of the medical profession are capable of meeting the situation, and meet it we must and will.

If I interpret correctly the attitude of the American Medical Association, which represents a very large section of medical opinion in the United States, it has affirmed over and over again its willingness and indeed its anxiety to do all in its power to see to it that no citizen of the United States is deprived of medical care, no matter what his financial station may be. Organized medicine in Canada has taken a similar stand, and yet

there are people both in the United States and in Canada who, for reasons best known to themselves, appear to get vicarious pleasure out of assailing the medical profession and questioning its sincerity. Evidence is not lacking that the medical profession has been subject to much buffeting in days which have gone, and we may expect to face many storms in the days that are to come. With proper perspective, however, we shall emerge into calm and peaceful waters, having full confidence in our ability to steer the ship to a secure haven.

Admitting, if I may, that there is an urge on the part of great masses of the public for some change to be brought about in medical practice, how best may we proceed to study the merits of the case, if merit there be? Accuracy is often born of trial and error. It is my view that we should accept all reasonable opportunities to demonstrate by trial, and possibly by errors too, well conceived plans whereby groups of persons may receive medical care, but the all-important consideration is this: The plans should be devised, worked out and put into operation with the fullest collaboration of the medical profession. Keeping this thought in mind I wish to present the attitude of the Canadian Medical Association with regard to the subject under discussion and to outline as briefly and concisely as possible some Canadian experiments in the field of medical economics.

As is well known, many persons hold to the belief that state medicine or health insurance or some modification of one or both, governmentally applied, is the answer to the whole problem. We as a profession know equally well that this is far from the truth. We know that state medicine or health insurance, partially or wholly under government control, is in effect in forty countries. It has been my privilege to visit many of these countries and to study the vast majority of health insurance plans now in operation. I say with all confidence that I do not know of one scheme or plan now in effect in any country that I would wish to see introduced into Canada.

The Canadian Medical Association has not authorized an expression of opinion either in favor of or opposed to the institution of health insurance in Canada, as our legal friends would say, the matter is still *sub judice*. But, for use in the event that some plan is proposed from outside the profession, which in actual experience has already occurred, the association has set forth what it believes to be necessary guiding principles by which it can carefully scrutinize and measure all such plans as are advanced. May I now present these principles:

1 That, in the provinces where health insurance is established, it be administered under an independent health insurance commission and that there be close cooperation between this commission and the provincial department of public health with a view to making full use of preventive services.

2 That a general health insurance board and local insurance boards be appointed, representative of all interested, to advise the responsible administrative authority.

3 That the professional side of health insurance medical service be the responsibility of the organized medical profession through the appointment of a central medical services committee and local medical services committees, to consider and advise on all questions affecting the administration of the medical benefit.

4 That the question of the establishment of local areas for health insurance administration be left to the decision of the individual provinces.

5 That the whole province be served by adequate departments of public health, organized on the basis of provision of individual health supervision by the health insurance general practitioner.

6 That there be a health insurance fund and that regional medical officers to act as supervisors and referees be appointed, paid and controlled by the central board or commission.

7 That medical care for indigents be provided under the plan, the government to pay the premium of the indigents, who then receive medical care under exactly the same conditions as the insured person.

8 That the plan be compulsory for persons having an annual income below a level which on investigation by competent local authorities proves to be insufficient to meet the costs of adequate medical care.

9 That the dependents of insured persons be eligible for the medical benefit.

10 That there be offered, on a voluntary basis, to those with incomes above the health insurance level, hospital care insurance and that this be administered as part of the health insurance plan, such hospital care not to include medical service other than hospitalization.

11 That the only benefit under the plan be the medical benefit.

12 That the medical benefit be organized as follows:

(a) Every qualified licensed medical practitioner to be eligible to practice under the plan.

(b) The insured person to have freedom of choice of medical practitioner and vice versa.

(c) The medical service to be based on the making available to all of a general practitioner service for health supervision and the treatment of disease.

(d) Additional services to be secured ordinarily through the medical practitioner.

(1) (a) Specialist medical service.

(b) Consultant medical service.

(2) Visiting nurse service (in the home).

(3) Hospital care.

(4) Auxiliary services—usually in a hospital.

(5) Pharmaceutic service.

(e) Dental service, arranged directly with the dentist or on reference.

13 That the insurance fund receive contributions from the insured, the employer of the insured and the government.

14 That the medical practitioners of each province be remunerated according to the method or methods of payment which they select.

15 (a) That the schedule of fees in any health insurance scheme be the schedule of fees accepted by the organized profession in the province concerned.

(b) That all schedules of fees be under complete control of the organized medical profession in each province.

16 That the contract-salary service be limited to areas with a population insufficient to maintain a general practitioner in the area without additional support from the insurance fund.

17 That no economic barrier be imposed between doctor and patient.

18 That the volume of work demanded from and the remuneration to members of the various professions be such as to assure a standard of service equal to or better than present day standards.

Does the setting forth of health insurance principles act as an invitation for health insurance legislation?

The Canadian Medical Association takes the view that, if governments—national or provincial—should take it on themselves to introduce legislation of a medico-economic nature, we, the members of the medical profession, should know in advance where we stand and under what conditions we would be willing to cooperate. We believe that a definition of policy predicated on sound thinking, and the keeping of a proper balance between medical ideals and medical practice, is desirable, and therefore, after several years of study and discussion within our component parts, there emerged these principles on which we believe that we may safely rest our case and if necessary base our will—

ingness to negotiate. We believe too that to be forewarned is to be forearmed. Time does not permit of a detailed analysis of these principles but it is our firm belief that a careful study of them will disclose that an earnest effort has been put forth to keep inviolate what we consider to be our inalienable rights in the realm of medical practice, while at the same time the rights of the public that great body whom we serve, have also been recognized and protected in a manner which should command respect and confidence. It will be observed that the medical profession has given ample evidence of its willingness to accept leadership and responsibility, an attitude of mind which the American Medical Association has so commendably recommended to its constituent societies and members for many years back as my memory serves me.

While I am on the subject of leadership in relation to medical economics, it would not seem out of place to say that the best conceived and executed plan which can be devised for adequate medical care for all the people, including the poor and needy, is but a poor stopgap for those in the lowest income group if nothing is done to provide work and wages and a decent standard of living for them. It seems to me that this is a field of thought and endeavor to which some well intentioned observers and social workers might give heed by way of diversion from their favorite pastime of assailing the medical profession for its alleged inability or unwillingness to provide adequate medical care for all the people.

#### HEALTH INSURANCE IN BRITISH COLUMBIA

One of the major Canadian experiments in medical economics, although it might be regarded so far as having come to naught, occurred in British Columbia, Canada's most westerly province. So much interest and attention have been directed to this experiment that I now propose to give the high lights of it as they concern the medical profession.

As far back as twenty years ago in March 1919 to be exact, the government of British Columbia appointed a select committee to inquire as to laws relating to mothers' pensions, maternity insurance, health insurance and public health nursing which were in force in other countries. Ten years later, in 1929, the government appointed a royal commission to inquire into all matters affecting maternity benefits and health insurance. In 1932 this commission reported and recommended the "early establishment in British Columbia of a suitable health insurance plan including Maternity Benefits." Nothing further was done until 1935, when the government issued a draft of a plan of health insurance. This draft bill was sent broadcast throughout the province. The public was asked to study it. Then there followed the setting up of a public hearings committee to receive expressions of opinion from public bodies, including the medical profession. Some of the points, both favorable and unfavorable, concerning the original draft bill which are of interest to the medical profession, follow.

1 The medical profession became aware of its provisions when the bill became public property.

2 It included cash benefits, which do not belong in a health insurance measure.

3 It included the indigent, for whom medical services were to be paid for by the government.

4 It provided for the insured a complete medical service with hospitalization, nursing and dental services.

5 It included all employees earning \$2,400 a year or less and also their dependents.

6 There was to be paid for complete medical services, including hospitalization, nursing and dental services, not less than \$10 and not more than \$13.20 per insured person a year, plus 5 per cent of the total annual expenditures on medical benefits for services of a general character.

7 The health insurance fund was to be formed by

(a) collecting from the employer 2 per cent of his pay roll applicable to insured persons,

(b) collecting from the employee 3 per cent of his wages,

(c) a contribution by the government of sufficient funds to cover the cost of medical benefits provided for indigents, plus half the cost of administration "provided that the contribution of the Province shall not be greater than \$1,200,000 in any one year."

The reaction of labor to the draft bill was on the whole favorable, although there was some objection to the 3 per cent levy on wages and a certain number urged that the upper income limit of \$2,400 a year should be removed entirely.

Industry protested that economic conditions in the province were such that it could not meet the additional tax which would be levied.

The medical profession, while objecting specifically to a number of the provisions in the bill (reference to which will be made later), strongly urged that, before any such legislation was enacted, a more intensive study be made not only in British Columbia but throughout Canada as a whole as to the need for legislation of this character.

In the spring of 1936 the legislature of British Columbia presented a radically altered bill, practically all the alterations being, in the opinion of the medical profession, of a retrograde character. Here are some of them.

1 The government agreed to advance \$50,000 for organization purposes, and there its financial responsibility ceased, obviously an actuarially undetermined piece of financing.

2 The indigent were excluded, with no alternative provision being made for them or their dependents outside the act. In other words, the indigent were left on the doctor's doorstep.

3 Many classes of low wage earners were excluded, including casual laborers, domestic servants, farm laborers and all employees earning \$10 a week or less.

4 Old age pensioners and widow pensioners were excluded from the benefits.

5 Contributions to the fund were greatly reduced,

(a) from the employer 2 per cent instead of 3 per cent and

(b) from the employee 1 per cent instead of 2 per cent, a reduction in funds that made the act still further actuarially questionable.

6 A complete medical service was still to be provided, including hospitalization and one half of the drug bill, although the financial basis had been gravely lowered.

7 Remuneration of the medical profession was to be "at the rate of not less than \$4.50 per annum per insured person eligible to receive benefits."

From a medical point of view, the act was clearly undesirable and unacceptable.

Although the party in power regarded the act as a government measure, it had a stormy passage through the legislature, finally emerging on March 31, 1936, to become effective on a date to be fixed by proclamation. After the passing of the act a health insurance commission was appointed, with very wide powers. The commission invited the medical profession to assist in working out details which would be satisfactory to both sides. Realizing that the legislature had spoken, the medical profession had no option but to attempt to make the best of the situation, but finally, after many con-

ferences, the committee representing the medical profession advised the commission that it could not accept the provisions of the act or work under it. It was decided to ask the entire medical profession to vote on the subject. When the ballots were counted, it was disclosed that 622 doctors had voted against accepting the scheme while thirteen had voted in favor of it. Fourthly, the medical profession announced in the public press that it could not undertake to provide medical services under the act, and on February 19 the premier of the province announced the postponement of the operation of the health insurance act, sine die. Three years has passed and the act remains inoperative. From the point of view of the medical profession, certain facts stand out and definite conclusions may be drawn.

1 The provincial government failed to secure the approval of the medical profession to the medical provisions incorporated in its health insurance act. This was a grave error because not only must the cooperation of the medical profession be obtained before any such act can be operated successfully but a government if it is to frame a satisfactory act should consult the medical profession at the outset and, to a large degree, be guided by medical advice. It is the right of the medical profession to be consulted and it should stand by that right.

2 A complete health insurance plan costs money, and no such plan will be successful if undertaken on a financial shoestring; furthermore, no scheme will be satisfactory or complete that does not (a) adequately remunerate those rendering service and (b) make provision for the indigent, old age pensioners and all low wage earners who are unable to provide medical services for themselves.

The British Columbia medical association is a division of the Canadian Medical Association, and the fight of the doctors in that province for economic justice and security was a fight in which the doctors throughout Canada felt themselves to be engaged. Consequently the Canadian Medical Association whole-heartedly supported the medical profession of British Columbia in the stand which it took. It is my firm conviction that the hope of doctors for fair treatment in any country must to a large degree rest in the organized medical profession, whose interests are neither selfish nor parochial but public spirited in the broadest sense of the term.

#### MUNICIPAL DOCTOR SCHEME

During the past twenty-five years there has developed in the province of Saskatchewan a plan which is known as the municipal doctor scheme. The story of the beginning and growth of this plan is a story of the origin of a unique system of socialized medicine which has served a definite purpose in providing medical services which it is alleged could not easily have been obtained through private practice.

For the purpose of local government, the province is divided into geographic units of from six to twelve townships, each township being an area 6 miles square. Units are authorized to fix a mill rate of taxation for the provision of medical services. In 1914 one of these rural municipalities had practically no crop and the local doctor was faced with the discouraging prospect of looking for a new field of endeavor or, as he viewed it, staying to starve. The municipality assumed the responsibility of taxation and guaranteed him \$1,500 for one year if he would stay. He did so, and thus began the scheme which today includes 121 doctors,

20 per cent of the 600 practicing physicians in the province, who are engaged either whole time or part time as municipal physicians. In 1919 legislation was enacted whereby a rural municipality might engage a physician on a salary not exceeding \$5,000 a year. In 1930 legislation permitted this salary to be increased to \$5,500 in some of the larger municipalities. In 1933 towns and villages in the province were extended similar taxing privileges, permitting them to engage physicians on a salary basis. In the main the contracts call for the provision of general medical services to include minor operations, maternity care, medical health inspection and immunization of school children. Practically all the contracts exclude major operations.

An analysis of this service brings out the following points with respect to remuneration for services rendered:

1 In a large group of municipalities, a capitation fee of as low as \$1.24 to as high as \$3.66 provides general medical services to a total of 77,421 persons for \$147,798.00, at an average per capita rate of \$1.94 a year.

2 In another group, of thirteen municipalities, including 116 townships, a capitation fee from \$1.29 to \$2.81 provides, in addition to general medical services, major operations within the competence of the municipal physician to perform, to a total of 30,964 persons for \$59,050, or an average per capita rate of \$1.91 a year.

3 In a third group of municipalities, the capitation basis varies from 92 cents to \$3.32 a year. A total of 34,276 persons pay a basic salary of \$39,630, or a capitation rate averaging \$1.74 a year.

One observer who has had an excellent opportunity to appraise the service has provided me with the following information:

#### Points in favor of the plan

1 A medical service is provided where otherwise there might have been none.

2 Pioneers who are developing the country have been guaranteed medical care, much to the advantage of the country as a whole.

3 The doctor is guaranteed a certain definite income, from which he can budget.

4 The plan tends to promote preventive medicine, in that it is to the doctor's advantage to keep his people well.

#### Points against the plan

1 It interferes with private practice in some areas.

2 It interferes with free choice of physician.

3 In many instances there is too much work for any one man to undertake.

4 The pay, although a burden on the municipality, is in the majority of instances inadequate for the work done.

5 Very few municipal doctors find time for post-graduate work or vacations.

6 A municipality is not a satisfactory unit for payment.

7 The doctor has no way of exacting remuneration from the municipality.

8 The scheme lends itself to doctors' bidding against one another for positions.

9 Municipalities on occasion allow a contract with a doctor to lapse, perhaps owing him considerable money, and then advertise for another incumbent.

10 The municipality may arbitrarily cut the salary, and the doctor can take it or leave it.

11 The doctor has no guaranty of tenure of office and therefore little protection such as would prompt him to buy property.

12 Arrears of salary in some instances exceed \$10,000, with little prospect of their being paid

A breakdown of one contract is shown in the accompanying table

According to the unit basis of cost of service, it is observed that the doctor was paid as follows

- 1 Office consultation (2 units), \$0.46
- 2 House call (3 units), \$0.69
- 3 Confinement (15 units), \$3.45
- 4 Major operation (50 units), \$11.50
- 5 Minor operation (10 units), \$2.30
- 6 Immunization (3 units), \$0.69

Why do well qualified medical practitioners accept these municipal doctor contracts? There are perhaps many reasons, but most emphatically it must be stated that the primary motivating influence is a desire to secure a guaranteed income while serving humanity in one's chosen profession. On the basis of remuneration received for work done, the plan should not be considered as providing adequate financial returns. Salaried appointments as municipal physicians would appear to leave much to be desired.

#### THE ONTARIO PLAN

Early in the recent depression through which the entire world has been passing, governmental authority in Canada decided that the unemployed and their dependents were entitled to food, fuel, shelter and clothing at the expense of the state. The medical profession contended that medical care for these less fortunate of our citizens was just as essential as food, fuel, shelter and clothing and that the state should not expect the doctor to contribute this service entirely at his own expense. In some parts of Canada this contention was heeded, and I shall now deal with the plan which was adopted in the province of Ontario.

Four years ago the Ontario division of the Canadian Medical Association entered into an agreement with the government of the province on the following terms:

For each person in the province in receipt of relief, including dependents (and at that time the number was approximately 400,000), the government agreed to provide the sum of 25 cents a month. The association in turn undertook to provide for relief recipients general practitioner services in the office and in the home together with domiciliary obstetric services. There was to be as complete freedom of choice of doctor and patient as obtains in private practice. No finer opportunity could have been afforded the medical profession to demonstrate its ability to carry out the very principles it had been advocating for years, namely that no third party should intervene in a plan of providing medical services to a cross section of the community.

Within thirty days the medical association, working through its fifty component branches, set up ninety-six medical committees, representing more than 4,000 practicing physicians, it being the duty of these committees in the respective areas to scrutinize and assess medical accounts and pass them on to the central administrative medical committee for final adjudication and payment. Rather than set up a special tariff for relief recipients, the association agreed to apply its regular tariff to the service, namely \$2 for an office call, \$3 for a house call and \$25 for a normal confinement, with additional allowances for mileage. It was of course recognized at the outset that the money available would not be adequate to pay assessed accounts in full, the profession did not expect that the taxpayers, of whom they form

a part, would be called on to pay 100 per cent of the medical bills for their less fortunate fellow citizens. Accordingly the plan adopted was as follows: Bills having been taxed, i. e. checked over as to their accuracy and fairness (and one should here interpolate that a very small minority of the profession were found to be unfair with their accounts), were then added up and the total was divided into the amount of money available each month, each doctor being paid pro rata according to the amount of his account and each month being considered a unit. At the end of two years the amount of money which the government agreed to pay was increased to 35 cents per relief recipient monthly, out of which the profession agreed to pay the druggists 6 cents a month for the necessary drugs and supplies.

What has four years of experience in providing medical care to this rather large number of people taught? I think a number of things of very definite interest and importance, certainly to Canada and perhaps to the medical profession in other parts of the world.

1 The profession has demonstrated that it can organize and conduct satisfactorily a plan of medical services on a group basis without any political, governmental or sociological interference.

#### Contract of a Municipal Doctor

Area covered	350 square miles
Population	2,800
Work done for the year 1936	
Office consultations	3,600
Country calls	800
Maternity cases	51
Minor operations	90
Major operations (within his competence)	15
Immunization	300 persons
Salary paid	\$4,500
Major operations (amount collected)	\$ 300
Total income	\$4,800
From this deduct	
For transportation (13,000 miles by car, 1,200 miles by snow plane, 250 miles by train)	\$1,550
For drugs	300
Net amount for services rendered	\$1,850
	\$2,950

2 The services available to a group such as that concerned demonstrated very clearly that morbidity quickly rises when resistance to meeting costs is removed. It was estimated at the inception of the scheme that morbidity might stand at somewhere between 6 and 8 per cent. What are the actual morbidity figures for this experiment? For the first year 12.78 per cent, for the second year 14.37 per cent and for the third year 15.40 per cent.

In respect of remuneration to the profession, the records show the following payments in relation to total accounts as taxed and approved: first year 45 per cent, second year 38 per cent and third year 51 per cent. (In the third year the 35 cents a month capita rate applied.)

Thus it will be seen that the doctors are contributing practically 50 per cent of the cost of medical services to this group. Moreover, information is now available as to the actual cost of such services, which information heretofore was not available in Canada.

What about the quality of the services rendered?

A short time ago, while engaged in preparing this paper, I directed this question to the minister in the government under whose regime general relief is administered. He assured me that, so far as the government is concerned, the service is highly satisfactory, that the

medical profession appears to be doing a splendid piece of work, that the relief recipients are satisfied with the care they are receiving and that the taxpayers who are providing the funds (over four years, approximately 4 million dollars) are satisfied that they are getting full value for their money

At no time has there been interference of any kind from any source with the administration of the scheme by the medical profession. Valuable statistics have been made available with regard to morbidity and service costs. A complete and unmistakable answer has been made to that section of the public who doubt the ability of the medical profession to organize and provide adequate medical care to a large group of people without the intervention of a third party. There is abundant proof of the satisfaction and confidence which has accrued to the profession in finding that it was able to discharge its responsibility to itself for the proper carrying out of this experiment in medical economics. If the profession can conduct an experiment of this magnitude for 400,000 people in the province of Ontario, I have not the slightest doubt that the profession anywhere on this great continent is capable of carrying out a plan of medical services for any section of the public so long as the administration is entrusted to the medical profession itself. The relationship between physician and patient has not been disturbed, and one cannot see why, in any scheme of group practice, that same relationship should not prevail. If medical science is to progress, if standards of medical practice are to continue to improve, if we are going to keep medicine pointing ever upward and onward to finer attainments and thus greater public benefit, we must see to it that we preserve against assault from every side a position of intimate relationship with the public whom we serve without the intervention of a third party.

#### CITY PLANS

In a number of cities in Canada somewhat similar schemes for medical relief have been devised.

For the past five years a complete medical service has been supplied in greater Winnipeg to those on relief. The average number has varied from 45,000 to 35,000. Treatment is provided in the office, home and hospital, dental, optical, x-ray and laboratory services are included.

A doctor, employed by the city, interviews all who apply for treatment, emergency patients excepted, and gives a permit to enable the patient to consult the doctor of his choice. The city reserves the right to have minor ailments, e.g. constipation and scabies, treated by the doctor controlling medical relief.

A board of four doctors, two employed by the city and two representing practitioners, decides disputed questions, grants or refuses authority for operations, unusual treatments and expensive laboratory or x-ray tests, and renders decisions on contested accounts. In many instances it seeks the assistance of a specialist or a consultant.

Accounts are rendered monthly by each practitioner on a reduced scale of fees. There is no capitation limit or fixed budget, but no doctor may collect more than \$150 a month.

In five years, disciplinary action has been requested for four practitioners of more than 300 who provide the service. There have been no cases of proved neglect by doctors, no tragedies and singularly few complaints by patients. Again the medical profession has supplied

the answer to the question of its ability to provide adequate medical care without the intervention of a third party.

#### VOLUNTARY HEALTH INSURANCE

In the field of voluntary health insurance an interesting experiment began in Ontario some eighteen months ago, when an organization known as Associated Medical Services was incorporated with the official blessing of the Ontario Medical Association, to offer complete medical, surgical, hospital and nursing service to those members of the community who were willing to budget for illness by paying regular premiums as follows:

Subscriber, \$2 a month  
First dependent, \$1.75 a month  
Second dependent, \$1.50 a month  
Third dependent, \$1.25 a month  
Fourth and other dependents, \$1 a month

During the first six months, 733 subscribers were enrolled. During the past twelve months this number has increased to 4,020. In one city in the province, 826 physicians of 950 have so far expressed their willingness to cooperate. There is of course free choice of doctor, and in all other respects the patient enjoys the same independence and freedom of action as obtains under ordinary private practice. The plan, organized and conducted by medical men on a nonprofit basis, appears to be giving complete satisfaction to an ever growing number of forehanded persons who desire to insure at a fixed premium against unpredictable costs of illness. Moreover, the relationship between doctor and patient is undisturbed, again emphasizing and proving the desirability and necessity of such confidential contact, and intervention, which is restricted to economics and not medical practice, appears in no wise to work a hardship but rather to solve for many persons a hazard which formerly produced much concern and often financial disaster.

#### CONCLUSIONS

Time does not permit of reference to other schemes being worked out in different parts of Canada. My only purpose in presenting a paper of this nature may be summarized as follows:

1 On behalf of the medical profession of Canada, I wish to say that organized medicine is fully conscious of the medical needs of the public and is willing and able to meet these needs.

2 The medical profession has demonstrated its ability to provide medical services for large groups of people under terms which give complete satisfaction to the recipients of the service and to the medical profession.

3 A critical analysis of various schemes already in existence discloses weaknesses in many of them which the profession properly recognizes and refuses to accept.

4 From experience in Canada I am confident that there is no need for persons outside the medical profession to assume that, unless they take it on themselves to arrange for adequate medical care for all the people, such care will be denied those who need it most.

5 And, finally, may I say that I bring you greetings from your colleagues north of the 49th parallel of latitude and wish to assure you that, like yourselves, we recognize that the interests of medicine know no geographic boundaries or other limitations and that, with you, we look forward confidently to never ending opportunities to serve our fellow men, not forgetting the high calling which is ours.

## OFFICIAL NOTES

ABSTRACT OF MINUTES OF MEETING  
OF BOARD OF TRUSTEES

The regular annual session of the Board was held at the Association headquarters on Feb 16 and 17, 1939. Space is not available for a complete report of the deliberations of the meeting, but a brief report is here given.

## APPOINTMENTS

The following appointments and additions were made to editorial boards of special journals, councils, bureaus and committees. Unless otherwise stated, the appointee succeeds himself.

*American Journal of Diseases of Children* Dr Horton Crisp, of Nashville to succeed Dr L R DeBuys, *Archives of Dermatology and Syphilology*, Dr Charles C Denme of Kansas City, Mo, to succeed Dr Martin F Luginan, *Archives of Internal Medicine* Dr Reginald Fitz, *Archives of Neurology and Psychiatry* Drs Louis Crumrine and S W Ranson, *Archives of Ophthalmology* Dr W L Benedict, *Archives of Otolaryngology* Dr Chevalier Jackson and Dr James A Babbitt of Philadelphia as additional member, *Archives of Surgery* Dr Wlaiman Walters and, as additional members, Dr Arthur W Allen of Boston, Dr Alfred Blalock of Nashville, Dr Lester R Dragstedt of Chicago and Dr W E Dandy of Baltimore, Council on Physical Therapy, Drs W E Garrey, W W Collett and John S Coulter, Council on Pharmacy and Chemistry, Drs David P Barr, J Howard Brown and C W Edmunds, and Dr Perrin H Long of Baltimore to succeed Dr E M Bailey, also as additional members Dr Elmer L Sevringhaus of Madison Wis, and Dr Stuart Mudd of Philadelphia, Council on Foods, Dr C S Ladd of Bismarck, N D, and Dr Tom D Spies of Cincinnati to succeed Drs E M Bailey (resigned) and Joseph Brennemann, Council on Industrial Health, Dr R T Legge of Berkeley, Calif, to succeed Dr Morton R Gibbons (resigned), Committee on Scientific Research, Dr Noble Wiley Jones, Committee for the Protection of Medical Research, Drs E C Cutler A C Ivy and William Pepper, and Dr John H Rice of New York to succeed Dr M C Winternitz.

The following physicians were appointed to represent the American Medical Association: Dr Roger I Lee, a member of the Board of Trustees, to represent the Association at the meeting of the British Medical Association in Aberdeen, Scotland, in July 1939, Drs Arthur W Booth and Thomas S Cullen, members of the Board of Trustees, to represent the Association at the meeting of the Canadian Medical Association in Montreal, the week of June 19.

## DATE FOR NEW YORK SESSION

The week of June 10, 1940, has been selected as the date for the New York session of the Association.

ADVISORY COUNCIL ON MEDICAL EDUCATION,  
LICENSURE AND HOSPITALS

The Board authorized the publication of an editorial on the proposed establishment of an advisory council on medical education, licensure and hospitals, and on the expressed willingness of the Council on Medical Education and Hospitals to participate in such a conference provided the House of Delegates so authorizes.

## CONFERENCES WITH RELATED ORGANIZATIONS

A conference between the Board of Trustees of the American Medical Association and representatives of the American, Catholic and Protestant hospital associations was held on Tuesday, February 14, and the Board voted to invite representatives of certain other related organizations to meet with it in the future to consider plans of medical service for the American people.

ADVISORY COMMITTEE TO COUNCIL ON MEDICAL EDUCATION  
AND HOSPITALS

Dr W S Leathers and Dr Herman Weiskotten were added to the Advisory Committee to the Council on Medical Education and Hospitals and have accepted appointment. The committee now consists of Drs S S Goldwater, Paul Titus M T MacEachern, W P Wherry, J R Neal, Donald C Balfour, C B Pinkham, Herman Weiskotten and W S Leathers, and Father Alphonse Schwitalla.

## IMMIGRATION OF EUROPEAN REFUGEES

Authorization was given for the publication of an editorial in *THE JOURNAL* giving information obtained by the Bureau of Legal Medicine and Legislation relative to the number of refugee physicians admitted to the United States since 1930, and the names of the two committees which have been established to investigate the refugee problem and which have received grants from the federal government for such investigations.

## COMMITTEE ON AMERICAN HEALTH RESORTS

A Committee on American Health Resorts, consisting of Drs Bernard Fantus (chairman), Chicago, W S McClellan, Stratton Springs, N Y, E M Smith, Hot Springs, Ark, M B Jarman, Hot Springs, Va, and W P Holbrook, Tucson, Ariz, has been appointed.

## REVISION OF "PERIODIC HEALTH EXAMINATION"

Authorization was given for the revision of "Periodic Health Examination" and for the selection of a committee to handle the revision.

## APPROPRIATIONS

Appropriations for the conduct of the work of the various councils, bureaus and committees, as well as the usual appropriations for medical and therapeutic research, were made.

SPECIAL ISSUE OF ARCHIVES OF PATHOLOGY IN HONOR  
OF DR S B WOLBACH

Authorization was given for the publication of a special issue of the *Archives of Pathology* in July 1940 to commemorate the sixtieth birthday of Dr S B Wolbach, who has been a member of the editorial board of that periodical since its establishment in 1926.

COOPERATION WITH NATIONAL CONGRESS OF  
PARENTS AND TEACHERS

The Board authorized the printing of the usual number of medical record forms for the summer round-up of school children by the National Congress of Parents and Teachers.

## EDUCATIONAL CAMPAIGN IN SYPHILIS

The Board expressed its approval of the educational campaign in venereal diseases conducted by the U S Junior Chamber of Commerce in St Paul in 1937, and of similar campaigns for the control of syphilis by the U S Junior Chamber of Commerce in other cities if conducted along similar lines with the approval of the local society.

## MISCELLANEOUS

Consideration was given to numerous other subjects and to routine matters.

REORGANIZATION OF JOINT COMMITTEE  
WITH NATIONAL EDUCATION  
ASSOCIATION

The Joint Committee on Health Problems in Education, in which the American Medical Association and the National Education Association have cooperated since 1911, held its twenty-eighth annual meeting at Cleveland, February 27 and 28. Dr Thomas D Wood, who had been chairman of the committee since its inception, announced his intention to resign at the 1938 meeting. The vice chairman, Dr Charles C Wilson of Hartford, Conn, immediately appointed a subcommittee to make plans for the future of the Joint Committee. Dr Wood's resignation was submitted in July 1938 to the president of the National Education Association, by whom he had been appointed, and was accepted. Dr Charles C Wilson was named acting chairman, pending reorganization of the committee.

At the meeting in Cleveland the committee was reorganized under the following general principles: 1 A Joint Committee shall be established of the two organizations as a whole and not of any department or section of either one. 2 It shall include no representatives of other health agencies and shall be strictly a joint committee of the participating organizations. 3 The committee shall consist of five representatives of each organization, who shall be appointed to serve one, two, three, four and

five years respectively for their first terms and for five year terms thereafter and shall not be eligible for more than two successive terms. 4 The committee shall have a chairman, a vice chairman and a secretary-treasurer, who shall be elected annually from among the members of the committee by the Hare system of proportional representation. The broad principles of rules of procedure were laid down and adopted. This reorganization had previously been approved in principle by the Trustees of the American Medical Association and the Executive Committee of the National Education Association.

After the consideration of routine business, the members of the committee voted to resign in a body, effective immediately on the appointment of the members of the new committee as provided in the reorganization.

The principal objectives of the committee were defined as follows: (a) to promote a better understanding between physicians and teachers, (b) to bring to bear on health problems in education the best thought in medicine and in pedagogy, (c) to identify health problems in education and endeavor to promote constructive solutions for them, (d) to seek publication of the conclusions of the committee through the columns of the periodical publications of the participating organizations whenever possible and to publish pamphlets principally as reprints or when special indications for such publication exist.

## RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title *Your Health*, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).

Changes in this time will be necessary to take into consideration daylight saving time. Announcement of this change will appear in advance in *THE JOURNAL*. Owing to network conflicts the Chicago broadcast will not occur at 1 p. m. on Wednesday but there will be a rebroadcast from a recording over Station WENR at 8 o'clock each Monday evening. The program broadcast each Monday will be identical with the network program of the preceding Wednesday.

It has been necessary to curtail the length of the series by omitting the last two programs, which would have been broadcast June 14 and June 21. The series, therefore, will end with the broadcast scheduled for June 7.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

March 29	Animal Diseases Transmitted to Man
April 5	Don't Believe Everything!
April 12	Learning to Live

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

*Change in Status*—H. R. 4492, the Treasury Department Appropriation Bill, was amended in the Senate to increase from \$440,000 to \$700,000 the amount appropriated by the bill for carrying out the provisions of the National Cancer Institute Act. The bill, having passed the House and Senate, will go to conference at which House and Senate differences will be adjusted.

*Bills Introduced*—H. R. 4634, introduced by Representative Carter, California, provides that citizens of the United States who during the World War enlisted as and served in the status of civilian employees of the Signal Corps, United States Army, American Expeditionary Forces shall be considered as having served in the military service of the United States. H. R. 4652, introduced by Representative Voorhis, California, provides that in the administration of laws pertaining to veterans, retired enlisted men of the Army, Navy, Marine Corps and Coast Guard, who served during a war period as recognized by the Veterans' Administration and who have been honorably discharged from such service, shall be entitled to hospitalization and domiciliary care in Veterans' Administration facilities on parity with other war veterans. H. R. 4893, introduced by Representative Angell, Oregon, provides for the reorganization of agencies of the government. H. R. 4934, introduced (by request) by Representative May, Kentucky, proposes to authorize the appointment of female dietitians and female physiotherapy and occupational-therapy aides in the Medical Department of the Army. H. R. 4942, introduced by Representative Stefan, Nebraska, proposes to make it unlawful to sell certain spirits containing alcohol produced from materials other than cereal grains.

### DISTRICT OF COLUMBIA

*Bills Introduced*—S. 1805, introduced by Senator King, Utah, and H. R. 5067, introduced by Representative Randolph, West Virginia, propose to establish a lien for moneys due hospitals for services rendered in cases caused by negligence or fault of others.

### STATE MEDICAL LEGISLATION

#### Colorado

*Bills Passed*—The following bills passed the house March 15. H. 466, proposing as a condition precedent to the issuance of a license to marry that each party to a prospective marriage present a physician's certificate that he or she has submitted to such examination, including a standard serologic test, as may be necessary for the discovery of syphilis and that in the opinion of the physician the party either is not infected with syphilis or

is not in a stage of that disease which may become communicable, and H. 470, proposing to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood within ten days of the first professional visit and to submit that sample to an approved laboratory for a standard serologic test for syphilis.

#### Delaware

*Bills Introduced*—S. 151 proposes that in any civil or criminal cause a licensed physician or a nurse shall not be allowed or compelled to disclose any information "which may be required [sic] while attending a patient in a professional capacity, and which is necessary to enable him or her to act in that capacity," except in the case of a patient under 16 when the information indicates that the patient has been the victim of a crime. S. 225 proposes that in the distribution of the assets of an insolvent decedent funeral expenses not to exceed \$400 and reasonable bills for medical attendance and for nursing during the last sickness shall be paid before any other claims against the estate.

#### Georgia

*Bill Passed*—H. 623 passed the house March 14, proposing so to amend the state constitution as to permit the county of Tift to increase its bonded indebtedness by \$50,000 to erect and equip a hospital "where medical and surgical treatment and care may be provided those in need of such."

#### Illinois

*Bill Passed*—H. 408 passed the house March 14, proposing to appropriate \$75,000 to the Department of Public Health for the purchase of pneumonia serum for distribution to the citizens of the state.

*Bills Introduced*—H. 391 proposes to require every physician or other person attending in a professional capacity a pregnant woman to take or cause to be taken a sample of her blood at the time of the first examination and to submit that specimen to a laboratory approved by the State Department of Public Health for an approved serologic test for syphilis. Such test may, on request of any physician, be made free of charge by the State Department of Public Health or the health departments of cities, villages and unincorporated towns maintaining health departments. S. 197 proposes that whenever in a civil or criminal proceeding issues arise on which the court deems expert evidence desirable it may appoint one or more experts, not exceeding three on each issue, to testify at the trial. The appointment of court expert witnesses, however, is not to preclude the parties from calling expert witnesses of their own, pro

vided the party calling an expert witness gives the court and the adverse party reasonable notice of the name and address of the expert to be called

#### Maine

*Bill Introduced*—S 378 proposes to authorize the court in a bastardy proceeding to order the complainant, her child and the putative father to submit to one or more blood grouping tests. The results of such tests will be admissible in evidence only in cases in which exclusion is established

#### Maryland

*Bill Introduced*—H 545 proposes to require every physician, pharmacist, dentist, hospital or nurse treating any person in Montgomery County for any injury which apparently has been caused by an automobile accident or by a lethal weapon to report the facts, as soon as practicable, to the county police

#### Missouri

*Bills Introduced*—H 605 purports by its title to amend the laws relating to midwifery by adding a new section, which would permit the State Board of Health to license a person to operate an "institution or establishment attempting to treat the sick or others afflicted with bodily or mental infirmities" by massage, exercise, steam, electrical or therapeutic baths, or rubbing with alcohol or other medicative substances, by and through the means of any system of remedial treatment consisting of kneading or rubbing [sic] the body, or by careful regulation of diet, food, etc., commonly known as Alimentary therapeutics, or by immersing, showering, massaging or washing the body or part of the body, by exposing the body to steam, vapor, hot air, or in which a current of electricity passes through the water, or in the application of hot sand or other heated material applied to the body, through or by any means whatsoever including a ray, electrical apparatus, mechanical contrivances, steam or electric cabinets or otherwise. H 604 proposes to enact a law regulating the manufacture, distribution or advertising of foods, drugs, cosmetics and devices

#### New Hampshire

*Bill Introduced*—S 30, to amend the medical practice act, proposes to restrict licensure to citizens of the United States

#### New York

*Bills Introduced*—S 1209 proposes to prohibit the retail sale and distribution, except on the written prescription of a licensed physician, dentist or veterinarian, of barbitol, sulfonethylmethane (trional), diethylsulfur diethylmethane (tetronal), carbromal, paraldehyde, chloral, chloral hydrate or chlorobutanol. S 1391 proposes to prohibit the performance of an operation the purpose or effect of which is to change or alter the skin or tissues of the fingers or thumbs so as to alter such person's finger patterns or fingerprints. The bill also prohibits the performing of any operation of plastic surgery on a known criminal the purpose or effect of which is to alter his personal appearance and make identification and apprehension difficult. A physician the bill proposes, must report immediately by telephone, if possible, to appropriate police officials all requests for operations which seem to come within the provisions of the bill. S 1424 and A 1927 propose to enact a law to be cited as the New York uniform food act to regulate the manufacture, distribution and advertising of foods. A 1982 proposes to authorize the formation of corporations to operate non-profit medical expense indemnity plans. A 1923 proposes to authorize medical societies to form non profit medical service corporations to operate non-profit medical service plans whereby medical treatment and care may be provided by the corporations to be formed or by physicians with whom they have contracted to such of the public as become subscribers to the plans under contracts which entitle each subscriber to certain medical care and treatment. At least a majority of the directors of such a corporation must be at all times members of a medical society but at least two directors must be laymen

#### Oklahoma

*Bill Introduced*—S 219 proposes to enact a law regulating the manufacture, sale and distribution of foods, drugs, cosmetics and devices

#### Ohio

*Bills Introduced*—H 565 and H 627 propose to authorize the sexual sterilization of epileptic, insane or feeble-minded inmates of state institutions

#### Pennsylvania

*Bills Introduced*—H 431 proposes to require every physician to notify the appropriate local health officer of every case of tuberculosis which comes under his professional observation. If that health officer learns that any person afflicted with tuberculosis is unable or unwilling to conduct himself in such a manner as not to expose persons with whom he may be associated to danger of infection, he may petition the court of common pleas of the appropriate county for an order directing the admission of such person to any approved hospital or institution established for the care of persons suffering from tuberculosis. The bill also proposes to make it the duty of the appropriate health officer to provide care, treatment, isolation or hospitalization to afflicted persons who are unable to pay for such care and treatment. H 440, to amend the workmen's compensation act proposes to make compensable as an "occupational disease" a contagious disease of any kind contracted by a person employed in or about any hospital to which persons having contagious diseases are admitted for treatment

#### Rhode Island

*Bills Introduced*—S 160, to amend the chiropractic practice act proposes among other things, that chiropractors "shall be entitled to the same rights and privileges pertaining to public health which may be imposed or given by law or regulation upon or to physicians qualified to practice medicine" except they shall not write prescriptions for drugs for internal medication," thus omitting the provision in the present law which specifically prohibits them from performing major surgery. H 809 proposes a system of compulsory and voluntary sickness insurance the benefits of which are to consist of cash and all forms of medical, dental and hospital service. Persons employed as farm laborers and persons employed by an employer having less than three employees in personal or domestic service are to be excluded from the compulsory insurance of the bill but are to be entitled to participate in the voluntary insurance. All other employees are embraced in the compulsory features of the bill

#### South Carolina

*Bill Passed*—S 330 passed the senate March 8 proposing to authorize the establishment and operation of a county hospital in the county of Charleston. The hospital is to provide medical attention and care for the indigent sick of the county and to provide hospitalization for others at such rates of pay as are commensurate with their ability to pay. The board of the hospital is also authorized to enter into contracts with any individual or corporation or professional organization for the furnishing of medical or surgical care on such terms and conditions as it deems advisable

#### Tennessee

*Bills Enacted*—S 411, nominally to amend the osteopathic practice act has been enacted as chapter 150, Public Acts 1939. It enlarges the legal scope of osteopathy, the present law which this act replaces permits a licentiate merely "to practice osteopathy" and seems not to permit a licentiate under it to practice surgery or to use drugs. The new law, however, provides that "Such certificate [referring to a certificate to practice osteopathy] shall entitle the person to whom it is granted to practice osteopathy in any county in this State, in all its branches, as taught and practiced by the recognized associated colleges of osteopathy, with the right to use such drugs as are necessary in the practice of osteopathy, surgery, and obstetrics, including narcotics, antiseptics, anesthetics and biologicals." H 836 has been enacted as chapter 102, Public Acts 1939, creating in the Department of Public Health a "Medical Care Division," to be headed by a licensed physician appointed by the governor. This division subject to the supervision of the Department of Public Health, is to administer and expend all sums that may be appropriated by the general assembly or made available by the federal government to the state, or from contributions from local units of government, or from other sources, for medical care in

accordance with any future act of the general assembly or of Congress "having as its objective the inauguration of a State and/or national program of medical care"

### Texas

**Bills Introduced**—Senate Committee Substitute for Senate 127 proposes to authorize the organization of corporations to operate non-profit hospital service plans whereby hospital care may be provided by such corporations, through hospitals with whom they have contracted, to subscribers to the hospital service plans. S. 352 to amend the provisions of the Texas workmen's compensation act which limits the period during which an employer must provide medical and hospital services to an injured workman to the first four weeks after an industrial injury, proposes to require an employer to provide such services where needed up to ninety-one days from date of injury.

### Wisconsin

**Bills Introduced**—S. 239 proposes that the provisions of the medical practice act shall not apply "to a total number of fifty medical physicians who may have been engaged in the actual practice of medicine or surgery in Germany, Austria, Czechoslovakia, or Poland" to whom licenses are issued in the manner

set forth in the bill. Briefly, the bill proposes that during the year commencing July 1, 1939, any physician residing in the state who may have, within the last ten years, been engaged in the continuous practice of his profession in Germany, Austria, Czechoslovakia or Poland may have a license issued to him by the board of medical examiners if he files an affidavit concerning his moral and professional character and the extent and nature of his practice in Europe and also presents an affidavit signed by at least two licensed physicians in the state concerning their knowledge of the applicant. The bill proposes that the number of licenses issued shall not exceed fifty for the year indicated and that no more than five such licenses may be issued in any one calendar month. A. 443, to amend the pharmacy practice act, proposes, in effect, to permit persons other than licensed pharmacists to sell aspirin, boric acid, camphorated oil, cod liver oil, iodine, milk of magnesia, mineral oil and peroxide. A. 436 proposes to provide for the sexual sterilization of feeble-minded, epileptic or insane inmates of state institutions. S. 251, to amend the law requiring male applicants for licenses to marry to present a physician's certificate as to freedom from venereal disease, proposes to require such certificates with respect to both parties to prospective marriages.

## WOMAN'S AUXILIARY

### Kansas

Mrs. Charles C. Tomlinson, president of the auxiliary to the American Medical Association, was the speaker at the meeting of the board of the auxiliary to the Kansas State Medical Society in Hays in December. Almost all of the nineteen members present lived more than a hundred miles away.

### Louisiana

The auxiliary to the Calcasieu Parish Medical Society distributed Thanksgiving baskets for needy families of Lake Charles. The auxiliary won over the American Legion Auxiliary in a radio quiz contest.

Col. Hollingsworth Barrett spoke on "Peace" at the November meeting of the auxiliary to the Caddo Parish Medical Society held in Shreveport.

The Orleans auxiliary is holding a series of lectures for members on the subject of socialized medicine, arranged on the advice of Dr. Shirley Lyons, president of the Orleans Medical Society.

### Minnesota

The auxiliary to the Hennepin County Medical Society sponsored the annual sale of articles made by patients of Glen Lake Sanatorium November 18 and 19. The proceeds, amounting to more than \$1,200, went to the patients who made the articles that were sold. At the December meeting each member and her guest gave a silver offering for "Sarahurst," a convalescent home for patients discharged from Glen Lake Tuberculosis Sanatorium.

The auxiliary to the Ramsey County Medical Society sponsored the play "The Dream of a Clown," given at the St. Paul Auditorium. The proceeds will be used for philanthropic purposes by the auxiliary.

The auxiliary to the Washington County Medical Society met at the home of its president, Mrs. J. W. Stuhr, November 8. Donations were given to the scout fund and to the high school "Radio Educational Project."

The auxiliary to the St. Louis County Medical Society held a rummage sale the proceeds of which were used for philanthropic activities.

Nearly 10,000 talks were written by Minnesota high school students on the subject "Tracking Down the Foe of Youth," a contest conducted by the Minnesota Public Health Association in cooperation with the woman's auxiliary of the state medical association. This was the eighth annual contest in which the auxiliary participated. Mrs. Martin Nordland, Minneapolis, former state president, represented the auxiliary on the committee of judges. The best talk from each high school, selected by a preliminary public speaking contest, was

entered in the state contest. From the manuscripts submitted, the judges selected the six talks that were presented in special broadcasts over WCCO the week of December 12.

### Mississippi

The auxiliary to the Central Medical Society met January 3 at the home of Mrs. B. J. Marshall, Whitfield. Mrs. Henry Boswell announced the anonymous gift of \$5,000 to establish the Preventorium Trust Fund. The Mississippi auxiliary has had as one of its projects the needs of the children at the state preventorium. It has provided funds for toys and handwork material. For years an essay contest on the preventorium and its work has been conducted in the junior high schools, a pamphlet arranged by the auxiliary and published by the state board of health being used as the source of information. This year at the close of the essay contest the auxiliary undertook to finish the trust fund, already started, to care permanently for the work they were financing. When this plan became public, a friend of the institution, a man who wishes to remain unknown, volunteered to create a perpetual fund to care for the needs of the children, which he has done. The auxiliary may now carry on its educational work and be relieved of its financial obligation.

The auxiliary assisted in the Christmas Seal Sale, having prepared several short talks which were sent to each auxiliary and each counselor and were given by members before clubs and church societies and over the radio.

### New Mexico

The auxiliary to the New Mexico Medical Society met at the home of Mrs. Harrison Brehmer in Albuquerque. Dr. L. Werner reviewed the book "The Country Doctor." At a later date it met at the home of Mrs. L. F. Elliott in Albuquerque. Christmas stockings were prepared for children at the Christina Kent Day Nursery.

### New York

Mrs. Milton Bergmann, president, spoke on the meaning of the caduceus before the auxiliary to the Medical Society of the County of Kings, December 13. Mrs. Edmund D. Clark, former president of the auxiliary to the Medical Society of the State of Indiana, was a guest. Another feature of the program was the showing of baby pictures of members of the auxiliary and an exhibit of their needlework and hobbies.

Miss Grace E. Allison, superintendent of the Samaritan Hospital, recently spoke on "Ideal Hospitals and Social Welfare" before the auxiliary to the Medical Society of the County of Rensselaer.

Mrs. Leslie Sullivan, president, auxiliary to the Medical Society of the County of Schenectady, was guest speaker before the auxiliary to the Medical Society of the County of Saratoga, December 5.

### ALABAMA

**New Regulations Governing License to Practice**—The Alabama State Board of Medical Examiners recently amended its rules governing the issuance of certificates of qualification to practice medicine. After the collegiate year 1938, any applicant for a certificate to practice will be required to serve at least one year of internship before such certificate will be issued. He will be permitted to take the examinations but the certificate will be withheld until the applicant complies with this requirement. Concerning graduates of European schools, the regulations read:

In the case of an applicant whether native born or foreign born who has graduated from a European School the following rules shall obtain:

- 1 Present a certified statement from the National Board of Medical Examiners of the United States setting forth that he has successfully passed all examinations written and oral required by this board; and
- 2 Either (a) present a certificate of qualification to practice medicine (a license) issued in the country of his nativity or in the country in which the medical school from which he graduated is located or (b) present a certificate setting forth that he has satisfactorily passed the federal examinations necessary to obtain licensure to practice medicine in the country in which the medical school from which he graduated is located.

All foreign born applicants shall first present at least first citizenship papers.

### CALIFORNIA

**Physicians' Art Exhibit**—The first annual exhibition of the Los Angeles Physicians' Art Society was held in the lounge of the Los Angeles County Medical Association recently. A special feature was a demonstration of stereoprojection of Kodachrome slides taken in Alaska by Dr. Orrie E. Ghrist. Officers of the society include Drs. Harold L. Thompson, president, and Katherine M. Close, secretary-treasurer.

**Society News**—Lee de Forest, Ph.D., Los Angeles, discussed "The Beginnings of Radio and the Application of High Frequency Current to Modern Medical Practice" before the Hollywood Academy of Medicine March 9.—Dr. William J. Kerr, San Francisco, discussed "A New and Rational Approach to the Etiology and Treatment of Angina Pectoris" before the San Diego County Medical Society, San Diego, February 14.—Dr. Rock Sleyster, Wauwatosa, Wis., President-Elect, American Medical Association, discussed aspects of the national medical problems before a joint meeting of the Los Angeles County and Southern California medical associations March 16.

### COLORADO

**Western Slope Spring Clinic**—The second annual Western Slope Spring Clinic, designed for physicians of Western Colorado and Eastern Utah, will be held at Grand Junction April 1-2, under the auspices of the Mesa County Medical Society. A clinical pathologic conference will be held Saturday. On Sunday the program will include the following speakers:

Dr. Carl W. Maynard, Pueblo. The Value of the Laboratory to the General Practitioner.  
Dr. Cuthbert Powell, Denver. Drainage of the Peritoneal Cavity.  
Dr. Roderick J. McDonald, Jr., Denver. Streptococcus Infections and Their Treatment.  
Dr. Frederick M. Heller, Pueblo. The Nephritides.  
Dr. Thomas Leon Howard, Denver. How Should the General Physician and Surgeon Evaluate Bladder Symptoms in Their Patients?  
Intermountain Clinic, Salt Lake City. Errors in Diagnosis and Treatment of Coronary Disease.

**Railroad Physicians' Meeting**—The tenth annual meeting of the Medical Association of the Missouri Pacific Railroad was held March 15-16 in Colorado Springs at the Antlers Hotel. The speakers included:

Dr. Charles O. Giese, Colorado Springs. The Practitioner and Pulmonary Tuberculosis.  
Dr. J. Sims Norman, Pueblo. Low Back Pain Associated with Spondylolisthesis.  
Dr. Casper F. Hegner, Denver. Surgery of Pulmonary Tuberculosis.  
Dr. John L. McDonald, Colorado Springs. Coronary Disease as an Industrial Problem.  
Drs. Harry C. Bryan, Colorado Springs and Lee B. Harrison, St. Louis. Pulmonary Tuberculosis. Missouri Pacific Employees—Results of Treatment for Fourteen Years.  
Dr. Oliver B. Zeinert, St. Louis.

In addition, there was a dental program and one presented by the section on ophthalmology and otolaryngology. At the

banquet Drs. George W. Bancroft, Colorado Springs, spoke on "Reconstruction of the Hip Joint", Hillel Unterberg, St. Louis, "Therapeutic Shock in the Psychoses," and Edward B. Liddle, Colorado Springs, "Renal Tuberculosis."

### DISTRICT OF COLUMBIA

**Graduate Courses in Ophthalmology—Pathology and Orthoptics**—George Washington University School of Medicine, Washington, will conduct a graduate course in ophthalmology April 10-15 as well as a practical course in surgery, pathology and orthoptics April 4-8. All requests for information should be addressed to George Washington University School of Medicine, 1335 H Street N.W.

### IDAHO

**Personal**—Dr. Charles R. Scott, Twin Falls, has been appointed superintendent of the State School and Colony for the Mentally Deficient, Nampa, succeeding Dr. D'Orr Poynter.

**Society News**—Dr. Charles H. Sprague, Boise, among others, discussed "Clinical Aspects of Pulmonary Tuberculosis" before the South Side Medical Society at Twin Falls January 12.—A recent meeting of the North Idaho District Medical Society was addressed in Lewiston by Dr. Frank C. Gibson, Potlatch, on "Fractures of the Jaw."

### ILLINOIS

**"The Family Doctor" at the Annual Meeting**—A health essay and poster contest under the title of "The Family Doctor" will be a feature of the annual convention of the Illinois State Medical Society in Rockford May 2-4. The contest is open to all high school students. Plans are also being made to hold a "Hall of Health" at the session this year.

### Chicago

**Hospital News**—Dr. Leo M. Davidoff, Brooklyn, lectured at Mount Sinai Hospital January 19 on "Pneumo-Encephalography and the Appearance of the Normal and Pathological Encephalogram."

**The Mary Redfield Plummer Lecture**—Clarence C. Little, Sc.D., director, American Society for the Control of Cancer and of the Roscoe Jackson Memorial Laboratory, Bar Harbor, Maine, will deliver the first Mary Redfield Plummer Memorial Cancer Lecture under the auspices of the cancer research committee of the Chicago Woman's Club March 29. His subject will be "Recent Advances in Cancer Research." The lecture is one in a series that has been sponsored for a number of years by the woman's club but was named in honor of Mrs. Plummer following her death last year. Mrs. Plummer was formerly parliamentarian of the club and one of the pioneer workers in cancer among club women.

**Symposium on Syphilis**—The clinical program committee of the venereal disease commission of the Chicago Medical Society has arranged to utilize the vast clinical material at the Municipal Hygiene Clinic, 27 East Twenty-Sixth Street, for presentation in the various phases of the subject of syphilis. The first of a series of monthly programs will be held March 27. Dr. Alexander S. Hershfield, consultant, Municipal Social Hygiene Clinic, will deliver the first lecture on neurosyphilis and present cases. Drs. Hyman H. Goldstein, Chicago State Hospital, and Victor C. Gonda, clinical professor of psychiatry, Loyola University School of Medicine, will carry on the discussion. The meetings, which are free, will be in the nature of a graduate course, according to the Chicago Medical Society Bulletin.

**Allergists Oppose Oral Pollen Treatment**—The following resolution has been adopted by the Chicago Society of Allergy. The members of the Chicago Society of Allergy, partly from their own experience and partly from a survey of both the published and some of the unpublished experimental and clinical results of oral pollen therapy, believe that the evidence of beneficial effect is at present not sufficient to warrant the commercial promotion of material for oral pollen therapy. Because of their controversial and contradictory nature, the published results of oral pollen therapy are inadequate to justify the commercial promotion of such a product. In addition, our investigation indicates that many men who have used oral pollen therapy have failed to publish their work because of the unsatisfactory results obtained. We therefore urge that the commercial promotion of oral pollen therapy should be deferred in the interest of the public and of the general practitioner until further experimentation now in progress has been reported.

**Dr Carl Beck Honored**—A dinner will be held March 28 in honor of Dr Carl Beck, formerly professor of surgery, Chicago College of Physicians and Surgeons, now the University of Illinois College of Medicine, in recognition of his seventy-fifth birthday and his completion of fifty years in the practice of medicine. A group of Dr Beck's friends is sponsoring the dinner at the Stevens Hotel at 7 o'clock. A native of Milan, Austria, Dr Beck took his degree in medicine at the Royal and Imperial University of Prague, 1889. He served as assistant in surgery and gynecology in the clinics at Prague, assisting first Professor Guessenbauer and later Dr Schauta, gynecologists of Vienna. He made several trips to America as stemmer surgeon in 1889-1890, settling in Chicago in the latter year to follow the general practice of medicine. He founded the St Anthony Hospital with the Sisters of Joliet. He is also a founder of the German Medical Society and the Bohemian Medical Society of Chicago. He is the author of "Principles of Surgery," 1905, and "The Crippled Hand and Arm," 1925, as well as of many articles in medical journals.

### KENTUCKY

**Personal**—Dr John L. Phyllan, Fort Thomas, was the guest of honor at a dinner recently at St Elizabeth's Hospital, Covington, celebrating his twenty-fifth year as a member of the staff. Dr Clifford N. Heisel, Covington, and Mr U. J. Howard, commonwealth's attorney of Kenton County, were the speakers. Dr James B. Mason, London, was recently elected president of the National Bank of London.

**Society News**—Dr Walter E. Vest, Huntington, W. Va., addressed the Boyd County Medical Society, Ashland, February 7 on the national health program. Dr Harrison H. Shoulters, Nashville, Tenn., addressed the Third District Medical Society in Bowling Green January 25 on medical economics and Dr James T. Gilbert Jr., Bowling Green, on "Diabetic Emergencies." Dr Emmet F. Horne, Louisville, addressed the Franklin County Medical Society, Frankfort, February 10, on "Critical Emergencies." Dr Thomas M. Marks, Lexington, presented a paper on epilepsy before the Montgomery County Medical Society, Mount Sterling, January 10. Dr Edward C. Ellett, Memphis, Tenn., addressed the Jefferson County Medical Society, Louisville, January 16 on "Dacryocystorhinostomy," as the guest of the Louisville Eye and Ear Society. Drs James Murray Kinsman and William M. Ewing, Louisville, addressed the society February 20 on "Practical Application of the Electrocardiogram" and "Primary Malignant Tumors of Bone" respectively. Dr Claude T. Wolfe addressed the Louisville Medical Surgical Society February 10 on "The Relation of Discs of the Nasal Accessory Sinuses to Eye Disorders."

### LOUISIANA

**Pneumonia Laboratory**—A laboratory for the study of pneumonia control will be established at the Louisiana State University Medical Center, New Orleans, under the direction of Dr Claude D. Head Jr., passed assistant surgeon, U. S. Public Health Service. Miss Helen Jarl, bacteriologist of the service, will be in charge. Once the unit is fully established, it will be maintained by the state, the public health service being responsible only for organization and for payment of the bacteriologist's salary, according to the *Tiger*.

### MASSACHUSETTS

**Personal**—Dr Morris Yoishus has resigned as clinical director of the Worcester State Hospital to enter the private practice of neurology and psychiatry; he had held the position for seven years, having been associated with the hospital for twelve. Dr Domizio A. Costa, Boston, has been appointed a member of the Massachusetts state board of registration in medicine.

**Mrs Roosevelt Guest Speaker**—Mrs Eleanor Roosevelt, wife of the President, will speak in Worcester Memorial Auditorium, April 27, under the auspices of the Worcester District Medical Society. The proceeds of the admissions will be used as the nucleus of a fund to finance the construction of a medical center building in Worcester to house the society's library and scientific activities.

**Special Society Meetings**—Dr Clarence Guy Lane discussed "Indications for the Use of Physical Agents in Dermatology" before the New England Society of Physical Medicine in Boston February 15. Among others, Drs Benjamin Castleman and Aubrey O. Hampton addressed the New England Pathological Society in Boston February 16 on "Correlation of Postmortem Chest Teleroentgenograms with Autopsy

Findings, with Special Reference to Pulmonary Embolism and Infarction." The New England Heart Association was addressed, among others, February 27, by Drs Roy L. Swank, Andrew Yeomans and Reno R. Porter on "The Reaction of the Cardiovascular System of Dogs to Intravenous Infusion."

### MICHIGAN

**New Deputy State Health Commissioner**—Dr Albert S. McCown, who recently completed a course at Johns Hopkins University School of Hygiene and Public Health, Baltimore, for a certificate in public health, has been appointed deputy state health commissioner, it was reported February 3. A graduate of Johns Hopkins University School of Medicine in 1918, Dr McCown has served as director of the child welfare department of the Washington state department of health and as director of the division on maternal and child health, Children's Bureau, U. S. Department of Labor, Washington, D. C. In his new appointment, Dr McCown will supervise county health programs and direct local health services, it was stated.

**Society News**—Dr Edwin M. Jameson, Saginaw Lake, N. Y., addressed a joint meeting of the Detroit Obstetrical and Gynecological Society and the Wayne County Medical Society February 6 on "The Problems of Pregnancy and Tuberculosis." The medical section of the county medical society and the Detroit Diabetic Association were addressed February 13 by Dr Irvine McQuarrie, Minneapolis, on "Significance of the Inorganic Metabolism in Diabetes Mellitus." Dr Plinn F. Morse, Detroit, discussed "Causes of Sudden Death" before the Ingham County Medical Society, Lansing, March 21. Dr E. Perry McCullagh, Cleveland, reviewed "Recent Trends in Clinical Endocrinology" at a meeting February 21.

**Graduate Conferences for Physicians**—Dr Benjamin W. Carey Jr., assistant professor of pediatrics, Wayne University College of Medicine, Detroit, will open a series of graduate conferences for physicians April 5, when he will discuss "Current Practice in the Treatment of Pneumonia in Infancy and Childhood. Report of Studies of Types of Organisms Involved, of the Status of Specific Sera and of the Use of Pyridine-Sulfanilamide." Other speakers in the series include:

Drs Richard M. McKern, Cordon B. Myers, Daniel P. Foster, Samuel S. Altshuler, all of Detroit; Diabetes.  
Dr David Slight, Chicago, Relationship of Psychiatry to Private Practice.  
Dr Cyrus C. Sturgis, Ann Arbor, Menace and Treatment of Obesity.  
Some Common Sense Remarks.

A course in pediatrics will be presented at the Henry Ford Hospital, Children's Hospital of Michigan and the Herman Kiefer Hospital, all of Detroit, April 3-5. Both programs are sponsored by the Wayne County Medical Society, Detroit Department of Health, Wayne University College of Medicine, Michigan Branch of the American Academy of Pediatrics, Michigan Society for Mental Hygiene, Inc., and the Michigan Department of Health.

### MISSOURI

**The Jackson County Forum**—Dr Harold S. Diehl, Minneapolis, will be the speaker in the Jackson County Health Forum April 19, on "The Common Cold." Subsequent lecturers in the monthly meetings include Drs Oscar W. Bethea, New Orleans, Louis J. Karnosh, Cleveland, Rock Sleyter, Wauwatosa, Wis., Thurman B. Rice, Indianapolis, and Franklin C. Bing, Ph.D., Chicago. Father Alphonse M. Schwitalla spoke in January on "How a Medical School Makes Doctors." Dr William A. O'Brien, Minneapolis, in February on "Health Problems of Middle and Late Life," and Dr Morris Fishbein, Chicago, Editor of *THE JOURNAL*, in March on "Cancer." The forum was organized in January 1938 under the auspices of the authorities of the accredited hospitals of Jackson County with the approval of the county medical society. The monthly lectures are open to the public. The city cooperates by providing free of charge a hall in the Municipal Auditorium, and the public relations committee of the Jackson County Medical Society acts in an advisory capacity to the health forum in selecting their speakers and planning their programs.

### NEW JERSEY

**Personal**—Dr William J. Carrington, Atlantic City, president of the Medical Society of New Jersey, recently received the annual achievement award of the Atlantic City Press Club. The honor is granted each year to the citizen considered to have done most to publicize Atlantic City.

**Society News**—At a meeting of the Essex County Medical Society, Newark, March 9, the speakers were Dr Arthur R. Casili, Elizabeth, 'Organization and Function of a Cancer Clinic', Edward W. Sprague, 'Surgery in the Treatment of Cancer', and Milton Friedman, 'Radiation Therapy in Cancer'. Dr Harrison S. Martland gave a demonstration of cancer material through the episcopes.—Dr Robert A. Kilduffe, Atlantic City, addressed the Essex County Anatomic and Pathologic Society in Newark March 23 on clinical utilization of studies of the blood.—Dr Thomas M. McMillan, Philadelphia, addressed the Camden County Medical Society, Camden March 7, on 'Rheumatic Fever and Rheumatic Heart Disease'.

### NEW YORK

**Lead Poisoning Traced to Nipple Shields**—The death of an infant from lead poisoning traced to lead nipple shields used by the mother recently led the Public Health Council to adopt an amendment to the Sanitary Code prohibiting the sale or use of such shields. The state department of health conducted a survey of drugstores, hospitals and physicians. The information showed that the use of lead nipple shields is not common but that it is easy to procure them.

**Gastro Enteritis Outbreak**—About half the 200 occupants of an institution in Dutchess County were affected in a recent outbreak of gastro enteritis traced to raw milk. No cases developed after December 22 when a pasteurized supply of milk was substituted for the raw supply. Mastitis was found in twelve of twenty-four cows in the herd supplying the institution's private dairy, and culture of the milk yielded a variety of organisms, including *Bacillus coli* and *Staphylococcus aureus*. One of the milk handlers had a digestive disorder for several days prior to the outbreak but continued to handle the milking machine.

### New York City

**Rockefeller Physiologist Drowned**—Alfred George Jacques, Ph.D. assistant in general physiology at the Rockefeller Institute for Medical Research, was drowned February 20 near Hamilton Bermuda, while dredging in shallow water for biologic specimens. Dr Jacques, a native of England had been on the institute staff since 1926 except for one year when he was a teaching fellow at Harvard University. He was 42 years old.

**Medicomilitary Exhibit**—An exhibit on medicomilitary preparedness will be presented at the Seventy-First Regiment Armory April 10 under the auspices of the medical officers of the organized reserve of the metropolitan area. In addition to exhibits that were shown at the first event of this kind last year, there will be novel presentations by veterinary and chemical warfare officers. Exhibits that will be repeated from last year include the four-wheel drive ambulance that can climb a 45 degree grade in rainy weather, a convertible ambulance body that can carry five ambulatory or four litter patients, an airplane crash outfit, and an arctic rescue unit. National Guard officers and officers of the regular army, the medical and veterinary professions, medical students and nurses and the public are invited to attend. The Armory is at Thirty-Fourth Street and Park Avenue. The exhibit will be on view from 7:30 to 11 p.m.

**Society News**—The Cornell University College Alumni Association will hold its annual 'Spring Day' April 20.—Mr. Louis H. Pink, superintendent of the Insurance Department of the State of New York, addressed the Medical Society of the County of Queens February 28 on 'Voluntary Hospital and Medical Association and the State'. Dr. Joseph Harkavy gave a Friday afternoon lecture March 17 on 'Allergy in Relation to Internal Medicine'.—Speakers at a meeting of the New York Roentgen Society March 20 were Drs. William Harris, Robert I. Walter and Arnold L. Bachman on 'Treatment of Ovarian Carcinoma' and Jacob R. Freid and Henry Goldberg, 'Postirradiation Changes in the Lung: A Clinical Roentgenological and Pathological Study with Emphasis on the Late and Terminal Stages'.—Dr. Ramon Castroviejo addressed the Sociedad Medica Hispano Americana of New York February 28 on 'Ocular Surgery'.

### NORTH CAROLINA

**Personal**—Dr. Ballard L. Norwood Jr. now on duty at a CCC camp at Greenwood S. C., has been appointed health officer of Granville County to succeed Dr. Joseph A. Morris, resigned. Dr. Norwood will take a course in public health at the University of North Carolina before assuming the position July 1.

**Addition to Duke Hospital**—Plans for an addition of 200 rooms to Duke Hospital, Durham, were recently announced. The new building will add from 100 to 120 beds, bringing the hospital's capacity to more than 550 beds. The new unit will be five stories high, the first two floors to be devoted to the private clinics and the upper three to private and semiprivate rooms. It is expected that the building will be ready for occupancy in the summer of 1940.

**Mental Hygiene Meeting**—Drs. Lauren H. Smith, Philadelphia and Fredric M. Hanes, Durham, addressed the North Carolina Mental Hygiene Society at its third annual meeting in Durham February 24 on 'Community Aspects of Mental Hygiene' and 'The Role the Medical School Should Play in Promoting Mental Hygiene' respectively. Officers were elected as follows: Dr. William Rancey Stanford, Durham, president; Mr. John S. Bradley, Durham, vice president; and Harry W. Crane, Ph.D., Chapel Hill, secretary.

### OHIO

**Grant for Research**—The Commonwealth Fund of New York recently granted to the Institute of Pathology at Western Reserve University School of Medicine, Cleveland, \$8,360 to be used in studies of the chemistry of immunity. This work has been in progress for two years under the leadership of Enrique Eduardo Ecker, Ph.D., associate professor of immunology.

**Medical Library Association**—Dr. Carl H. Lenhart was reelected president of the Cleveland Medical Library Association at the annual meeting January 20 and Dr. Frank S. Gibson was made chairman of the board of trustees. Dr. Charles W. Stone, retiring chairman of the board, reported that the library now has more than 53,000 volumes, it subscribes to 444 journals in various languages and during 1938 had 12,828 readers. Dr. Louis J. Karnosh gave an address at the meeting entitled 'The Psychiatrist Considers Bibliomania'.

**County Society's Radio Program**—The Summit County Medical Society, Akron, is presenting a series of dramatized radio programs entitled 'The Durand Baby' over Station WADC in Akron which began Saturday, March 11. Local physicians accompany the dramatizations with a three minute summary of the educational features of the program. Actors are being obtained from the Radio Speech Department of the University of Akron. The scripts are furnished by the Bureau of Health Education of the American Medical Association. Additional series of dramatized programs are contemplated when 'The Durand Baby' series has been finished.

### PENNSYLVANIA

**Society News**—Dr. George J. Thomas, Pittsburgh, among others, addressed the Westmoreland County Medical Society at a meeting at the Mountain View Hotel near Greensburg, on recent developments in anesthesia.—Dr. Russell L. Cecil, New York, addressed the Cambria County Medical Society, Johnstown, March 9 on pneumonia.—Dr. Frank W. Burge, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, March 14 on 'Trends in the Diagnosis and Treatment of Pulmonary Disease'.—Dr. Charles Mazer, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, March 10 on 'The Uses and Abuses of Endocrine Products'.

### Philadelphia

**Society News**—At a meeting of the Philadelphia Neurological Society February 24 the speakers included Drs. Michael Scott and Ernest E. Aegerter on 'The Possible Role of Arsenic in Disturbances of the Nervous System Attributed to Avitaminosis, with Special Reference to Pellagra'. Ernest A. Spiegel, Philadelphia, and Norman P. Scala, Washington, D. C., 'Interference Phenomena Between Optokinetic and Labyrinthine Nystagmus'.

**Portrait of Henry Phipps**—An oil painting of Mr. Henry Phipps was presented January 20 to the Henry Phipps Institute of the University of Pennsylvania by members of the Phipps family. Thomas S. Gates, LL.D., president of the university, accepted the gift, which was presented by Dr. Charles J. Hatfield, associate director of the institute, on behalf of the donors. Dr. Esmond R. Long, director, reviewed the institute's scientific achievements.

**Annual Banquet**—The Northern Medical Association of Philadelphia held its ninety-third annual banquet, March 20, with Dr. David Riesman as toastmaster. The guests of honor

were Drs Isidore W Held, clinical professor of medicine, New York University College of Medicine, New York, George M Dorrance, professor of faciomaxillary surgery, University of Pennsylvania School of Medicine, Randle C Rosenberger, professor of preventive medicine and bacteriology, Jefferson Medical College, and Edward J G Beardsley, clinical professor of medicine, Jefferson Medical College. Dr Beardsley spoke on "Medicine—Yesterday, Today and Tomorrow."

**Auxiliary Sponsors Annual Health Institute**—The ninth annual health institute sponsored by the Woman's Auxiliary to the Philadelphia County Medical Society will be held April 11. The program is planned to indicate "Seven Stages of Health" with the following speakers

Dr Philip F Williams Prenatal Stage  
Dr Edward L Bruer Infant Stage  
Dr Howard Childs Carpenter Childhood Stage  
Dr Charles W Dunn Adolescent Stage  
Dr Charles L Brown Maturity Stage  
Dr Percil Brooke Bland Menopause Stage  
Dr Edward L Bortz After Sixty Stage

Dr Francis F Borzell, president of the Philadelphia County Medical Society, will preside at the morning session and Mrs Walter F Donaldson, Pittsburgh, president of the Woman's Auxiliary to the Medical Society of the State of Pennsylvania, at the afternoon session

### Pittsburgh

**Society News**—At a meeting of the Pittsburgh Surgical Society March 10 the speakers were Drs Stuart N Rowe, on "Treatment of Brain Abscess", John W Stinson, "Pulsating Tumor of the Orbit", James A Cowan Jr, Samuel R Haythorn and William H Guy, "Hemangiomas, Their Pathology and Technic of Removal", and George V Foster, "Technic of Fixation of Bone Grafts".—At a meeting of the Pittsburgh Academy of Medicine February 28 the speakers were Drs George E Martin, on "Primary Tuberculosis", deWayne G Richey, "Chemotherapy in Otolaryngology," and Harold W Jacob, "Considerations of Lymphoblastoma from a Radiologists Standpoint"

### TENNESSEE

**Graduate Lectures in Pediatrics**—The committee on graduate instruction of the Tennessee State Medical Association is sponsoring a course in pediatrics organized in the same manner as one on obstetrics recently completed. Instruction began February 20 in the first circuit, which includes the following towns: Bolivar, Brownsville, Covington, Jackson and Selmer. The course will cover the state in two years. The lecturer is Dr Willis H Thompson, Minneapolis. The subjects to be covered will be the growth and development of the normal infant, breast feeding, artificial feeding of the normal infant, difficult feeding cases, the premature infant, gastrointestinal diseases, prevention and treatment of contagious diseases, care of the allergic child, tuberculosis and congenital syphilis and respiratory infections. Dr John M Lee, Nashville, is chairman of the committee on postgraduate instruction. Contributing agencies that have made this work possible are the Vanderbilt University School of Medicine, Nashville, the University of Tennessee School of Medicine, Memphis, the Tennessee State Medical Association, the State Department of Health and the Commonwealth Fund of New York.

**Society News**—Drs James E Paullin, Atlanta, and James S McLester, Birmingham, addressed the Davidson County Medical Society, Nashville, January 26 on "Diabetes" and "Newer Knowledge of Nutrition and Vitamins" respectively.—Nashville physicians presented the program at a meeting of the Tri-County Medical Society (Henry, Weakly and Carroll counties) in Huntington February 7. Drs John O Manier on "Recognition and Management of Certain Vascular and Cardiac Emergencies", Charles M Hamilton, "Value of X-Ray Therapy in Ordinary Infections," and Leonard W Edwards, "Surgical Management of Peptic Ulcers".—Dr William J Cameron, Sweetwater, addressed the Monroe County Medical Society, Sweetwater, January 31 on "Physiology of the Ovary".—Dr John M Boylin, Bristol, Va., addressed the Sullivan-Johnson County Medical Society in Bristol February 1 on hypothyroidism.—Dr Harrison H Shoulders, Nashville, addressed the Memphis and Shelby County Medical Society January 17 on medical economics.—Dr Charles Gordon Heyd, New York, addressed the Nashville Academy of Medicine and Davidson County Medical Society February 7 on "Gallbladder Disease."

### VIRGINIA

**Personal**—Dr Robert B Hightower, who has been instructor in pediatrics under the auspices of the department of clinical and medical education of the Medical Society of Virginia, has resigned to accept a position as assistant director of school medical inspection in the District of Columbia.—Dr Reid White Jr, Lexington, who has been physician to Washington and Lee University for several years, has been appointed full time medical director.

**Hospital News**—Dr David L Harrell Jr, first assistant physician at the State Colony for Epileptics and Feeble-minded, Colony, has been appointed superintendent of a new institution at Petersburg for the care of the Negro feeble-minded. The new colony was to start operations January 1.—Dr George B Arnold, superintendent of the State Colony for Epileptics and Feeble-minded, Colony, has been appointed to the state advisory board on mental hygiene.—Dr James B Nichols, medical director of Catawba Sanatorium, Catawba Sanatorium has been named superintendent, a new position, according to a newspaper report.

### WEST VIRGINIA

**Pilgrimage to Pittsburgh**—The West Virginia Obstetrical and Gynecological Society will make its annual clinic pilgrimage April 3-4 to Pittsburgh. The group will visit operative clinics at Magee, Pittsburgh and Mercy hospitals and will hear a symposium on gynecology and obstetrics, led by Dr Paul Titus at St Margaret Memorial Hospital. They will also visit Allegheny General and Montefiore hospitals.

**Society News**—The Taylor County Medical Society was the first in the state to report all 1939 dues paid.—Dr Louis H Douglass, Baltimore, addressed the Kanawha County Medical Society, Charleston, February 14 on "Analgesia in Obstetrics".—Dr James Edwin Wood Jr, Charlottesville, Va., addressed the Raleigh County Medical Society, Beckley, February 16 on "Recent Advances in the Study of Hypertension and Their Influences on Therapy."

### GENERAL

**Physicians Wanted for CCC Duty**—Vacancies now exist in the Civilian Conservation Corps in the Eighth Corps Area wherein the services of civilian physicians can be utilized as contract surgeons. Applicants should be graduates of class A medical schools. Applications should be addressed to The Surgeon Headquarters Eighth Corps Area, Fort Sam Houston, Texas.

**Examinations in Internal Medicine**—Written examinations for certification by the American Board of Internal Medicine will be held in various sections of the United States on the third Monday in October and the third Monday in February. Formal application must be received by the secretary before August 20 for the October examination and by Jan 1, 1940, for the February 1940 examination. Application forms may be obtained from Dr William S Middleton, secretary, 1301 University Avenue, Madison, Wis.

**Committee to Aid Settlement of Foreign Physicians**—Announcement is made by Dr Laurence Farmer, executive secretary of the Emergency Committee in Aid of Displaced Medical Scientists, that a committee entitled "Central Committee for the Resettlement of Foreign Physicians," has been established at 165 West Forty-Sixth Street, New York City, with the objective of handling the problems of the practicing refugee physician. In association with this committee, the Emergency Committee in Aid of Displaced Foreign Medical Scientists will take over the question of placement of research workers engaged in full-time laboratory or clinical investigation.

**Meeting of Anatomists**—The fifty-fifth session of the American Association of Anatomists will be held in Boston April 6-8 at the invitation of Boston University School of Medicine, Harvard Medical School and Tufts College Medical School. Meetings will be at Harvard and headquarters at the Hotel Somerset. More than 100 papers will be presented and Friday afternoon will be devoted to demonstrations. Dr Stephen W Ranson, Chicago, will deliver his presidential address Thursday afternoon, April 6, on "The Hypothalamus as a Thermostat Regulating Body Temperature." The meeting will end with a general session at which the following invited speakers will appear: Dr George W Corner, Rochester N Y, on "Sus Mus and Rhesus: A Retrospect of Twenty-Five Years", Edgar Allen, Sc D, New Haven, Conn.,

"Some Recent Studies of Reproduction and Associated Inducements," and Carl G. Hartman, Ph.D., Baltimore, "Studies on Reproduction in the Monkey and Their Bearing on Gynecology and Anthropology."

**Associated Postgraduate Committees**—The Associated Postgraduate Committees, a national organization of the graduate committees of the state medical societies has drawn up a constitution and a set of by-laws to be acted on at its meeting in St. Louis May 17. The organization is a voluntary association of the state committees to assist each other in furthering graduate education among the entire medical profession and to cooperate with the Council on Medical Education and Hospitals of the American Medical Association and all other special organizations composed of members of the American Medical Association as well as with the U. S. Public Health Service, the U. S. Children's Bureau and other federal and state agencies who seek to give graduate instruction to the medical profession. The Associated Postgraduate Committees was organized during the annual session of the American Medical Association in Atlantic City in June 1937. At a meeting in San Francisco in June 1938 it was recommended that the Council on Medical Education and Hospitals of the American Medical Association continue the collection of information on graduate education, especially in regard to graduate instruction for practitioners, and that *THE JOURNAL* should be requested to emphasize the importance of graduate extension courses.

**International Congress for Microbiology**—The third International Congress for Microbiology will be held at the Waldorf Astoria Hotel New York, September 2-9, under the presidency of Dr. Thomas M. Rivers, New York. All persons interested in microbiology are entitled to become members of the congress on payment of a fee of \$5, and prospective members are urged to register in advance by mail. Scientific sessions of the sections of the congress will be held each morning; afternoon sessions of the whole congress will take place on Monday, Wednesday and Friday. Among those who will speak at the general sessions according to the preliminary program, are:

Dr. Paul G. Fildes, London Bacterial Nutrition  
Dr. A. J. Kluyver, Delft Bacterial Metabolism  
Prof. John R. Marrack, London Immunochemistry  
Prof. Eduard Reichenow, Hamburg Endothelial Development of the Malarial Parasite  
Wendell M. Stanley, Ph.D., Princeton N. J. Viruses  
Dr. Arne Tiselius, Uppsala Sweden Electrophoresis

Sections have been arranged for the following topics: general biology, variation and taxonomy, general biology, microbiologic chemistry and physiology, viruses and viral diseases, rickettsiae and rickettsial diseases, protozoology and parasitology, fungi and fungous diseases, medical and veterinary bacteriology, agricultural and industrial microbiology, and immunology. Inquiries should be addressed to the office of the general secretary, Dr. Martin H. Dawson, College of Physicians and Surgeons, Columbia University, 620 West One Hundred and Sixty-Eighth Street, New York.

### LATIN AMERICA

**Lectures in Havana**—A group of the faculty of Cornell University Medical School, New York, lectured at the University of Havana, Cuba, February 27 to March 7. The following lectures were presented:

Symposium on Diagnosis and Treatment of Peptic Ulcer: Drs. Arthur L. Holland, George J. Heuer and Sydney Weintraub  
Symposium on Diseases of the Biliary Tract: Drs. Weintraub and William DeWitt Andrus  
Intestinal Tuberculosis: Secondary Ulcerative and Hypertrophic: Dr. Edgar Mayer  
Surgery of the Common Bile Duct: Dr. Andrus  
Symposium on Diagnosis and Treatment of Chronic Ulcerative Colitis: Drs. Heuer and Thomas T. Mackie  
Diagnostic Methods in Gastroenterology: Drs. Holland and Weintraub  
Nutritional Deficiencies in Relation to Chronic Gastrointestinal Disease: Dr. Mackie  
Newer Concepts of the Therapy of the Intestinal Parasites: Dr. Wilson G. Smilie  
Symposium on Everyday Problems in the Differential Diagnosis of Chronic Pulmonary Disease: Drs. Mayer and Weintraub

### CORRECTION

**Average Census of Patients in Hospital**—Bryan Memorial Hospital, Lincoln, Neb., writes that it should have reported eighty patients as the average census for that hospital for the last year rather than sixty as was reported and published in the Hospital Number of *THE JOURNAL*, March 11, page 963.

### The Action of Alcohol

In 1916 an advisory committee was appointed by the Central Control Board (liquor traffic) to consider the physiologic action of alcohol and particularly the effects on health and industry of beverages of various alcoholic strengths. The committee consisted of the pharmacologists Cushny and Dale, the physiologist Sir Charles Sherrington, the pathologist F. W. Mott, the psychologist William McDougall, the statistician Major Greenwood, and others who produced a report in 1918. On the dissolution in 1921 of the board, the government invited the Medical Research Council to reappoint the advisory committee, who produced in 1924 a second edition. With a continued demand for the report, further revision became desirable. A third edition has now been produced by Dale, Greenwood Mellanby, the psychologist C. S. Myers and Sir Charles Sherrington, in the form of a book of 175 pages, entitled "Alcohol, Its Action on the Human Organism." It is the most authoritative teaching extant on the subject and covers all the points which are still a subject of discussion. Following are some of the conclusions:

Alcohol is rapidly absorbed from the stomach and intestine and distributed by the blood to the different organs. A variable but always small proportion escapes unchanged in the breath and urine. The rest is slowly oxidized, disappearing from the blood at the rate of about 0.185 cc. per kilogram of body weight an hour. The energy liberated by the combustion of a moderate amount of alcohol can be used by the body, and therein lies the whole value of alcohol as a food. But in this value alcohol has no advantage over the much cheaper sugar and its action as a drug has to be considered. This is mainly on the nervous system. Alcohol has no practical value as a direct stimulant of the heart in cases of threatened failure. When it appears to promote recovery from fainting, this is due to its irritant action on the mucous membrane of the mouth and is comparable to the action of smelling salts. When, in conditions of more protracted cardiac weakness, alcohol has a beneficial effect, this is due mainly to its mildly sedative action, relieving the centers which modify the action of the heart from the disturbing influence of pain and anxiety. The mildly narcotic action of alcohol is the most important effect from the therapeutic point of view. It may relieve distress and promote sleep, but it must be prescribed with care and judgment. During convalescence or in a chronic illness it may improve the appetite.

### ALCOHOL AND ROAD ACCIDENTS

Alcohol impairs skilled movements, and this fact is most important in the driving of automobiles. Vernon made an experimental study, by means of an artificial motor-driving apparatus, on the effects of small quantities of alcohol (from 20 to 45 cc. in the form of whisky) taken on a practically empty stomach, on the driving capacity of various persons. He found that by far the majority drove more quickly and more erratically than in normal circumstances. For the most part they did not realize that they were driving faster, but one deliberately drove more slowly because he realized his reduced control and several drove for short distances with a rush and then slowed down before again driving faster. There was far greater variability not only in speed but also in accuracy and carefulness after alcohol had been taken. This was noticeable even after the amount of alcohol was reduced to

that contained in half a tumbler of mild beer (5 cc) Some persons were certain that they were driving better although they were driving worse Other experiments revealed not only an impairment of attention to signals and environment but also slower responses of the eyes, hands and feet There were wide individual differences in the mental effects, depending on the kind of alcoholic drink and previous habituation to alcohol

### Organization of Medical Services in War

In an address to representatives of the profession at the house of the British Medical Association, Dr Walter Elliot, minister of health, explained the medical arrangements which have been made for war The country had been divided into twelve regions, each controlled by a regional commissioner, who would have a staff of some magnitude On this staff would be a principal medical officer to supervise and control all the medical services in his area He would have a number of medical officers working under him, including a hospital officer The medical staff would see that supplies of bedsteads, bedding, dressings and drugs were available The ministry of health would collaborate with the central and local emergency committees of the British Medical Association The central committee had compiled a register comprising 95 per cent of the medical profession, showing each physician's special qualifications and experience and the type of war work for which he considered himself best suited The ministry of health, having under its supervision the organization of emergency hospital services, first aid posts and ambulance services, could earmark beforehand a certain proportion of physicians to their war time jobs There were five groups (1) physicians who could give full time service in the forces, (2) those required for hospital service, (3) those to control the first aid posts, (4) medical officers of government departments and local authorities and (5) medical boards for examination of recruits There would remain a number of general practitioners who would maintain the essential medical services for the civilian population Physicians engaged whole time in civilian casualty service would be paid at rates comparable to those of the army medical service Those serving at first aid posts would be paid at the rate of \$7.50 for two hours and \$15 for a longer period

### Society for the Protection of Science and Learning

The Royal Society in combination with the British Academy gave a reception to the scientists and scholars who have taken refuge in this country from the persecution on the continent and are under the care of the Society for the Protection of Science and Learning The guests were received by the president of the Royal Society, Sir William Bragg As usual with the receptions of the Royal Society, the ambassadors accredited to Great Britain were invited but not those of the two countries principally responsible for the persecution This reception is one of a number of meetings to be held in London and throughout the country to make known the work which is being done for the refugees Meetings under distinguished patronage have been held in the Great Hall of University College, London, and at the Universities of Oxford and Cambridge under the presidency of the vice chancellors In the *British Medical Journal* Prof Major Greenwood, FRS, makes an appeal on behalf of the Society for the Protection of Science and Learning He argues that scientists trained in different schools from ours have different points of view and bring here a new outlook What is good in their methods will be grafted onto our stock and the range of scientific work will be increased If we are to live under the menace of a world war, to shelter medical scientists is to add to our resources In the event of what is euphemistically described as "an emergency," the supply of technicians will fall short of the demand

and the new source of supply would be valuable Professor Greenwood draws a parallel with Huguenot persecution, by which France lost her keenest brains and nimblest fingers and other countries, particularly England, gained Huguenots introduced new industries and distinguished themselves in all the higher walks of life An example, among many others, is De Moivre, who came to England a poor refugee He was a great mathematician, and the time came when Newton was asked questions about his discovery of "fluxions" (the differential calculus) and replied "Go to Mr De Moivre, he understands these things better than I do"

### Medical Arrangements for a National Emergency

In the "Statement Relating to Defense" submitted to parliament, which shows that the estimate of \$7,500,000,000 given two years ago has been substantially exceeded, the medical arrangements are described as follows Plans have been completed for finding nearly 200,000 beds in existing hospitals and institutions within twenty-four hours after a state of emergency is declared by sending patients home and transferring them to other accommodations and by putting additional beds and equipment in the wards Another 100,000 beds will be obtained later by using parts of hospitals not at present used as wards For this purpose 50,000 beds and mattresses have been obtained and already are in process of distribution Orders have been placed for 200,000 blankets, and tenders have been asked for a further supply of beds Plans have also been made for linking the hospitals in war time and are being discussed with the hospital authorities The health departments' hospital officers have listed buildings and land adjoining hospitals suitable for expansion, and plans for new hospital units are under consideration

The government has accepted the recommendations of the committee on evacuation in favor of the transfer, within the limits of accommodation in less vulnerable areas, from densely populated areas of persons who could be spared An emergency scheme, prepared at the time of the crisis in September and modified in the light of experience then gained can be put into force at any time A circular letter has recently been sent to all local authorities in receiving areas asking for an immediate survey of available accommodations It is proposed that school children shall be evacuated under the supervision of teachers and other helpers, and young children with their mothers

By the end of the year 40,000,000 respirators for the public had been distributed to the local authorities During the crisis in September they were distributed to the public Large orders have been placed for the various types of equipment required for air raid personnel Discussions have taken place with the persons in charge of electricity, gas and water undertakings, with railway and transport companies and with the London transport board and dock and harbor authorities on the special measures to be taken for protection against air attack

### An Emergency Obstetric Service

An emergency obstetric service is being introduced in this country and has just come into force in London The object is to deal with the acute obstetric emergencies of patients who cannot be moved to a hospital without undue risk and who cannot be adequately dealt with by the consultant obstetric service of the borough in which they live The new service is designed not as an alternative to hospital treatment but solely for cases in which removal to a hospital would be dangerous It is anticipated that the majority of patients for whom it will be used will be suffering from postpartum hemorrhage, and the emergency unit will have available the apparatus for blood transfusion

In London the physician or midwife in charge will send a telephone message to the London County Council Ambulance

Service and ask for the emergency obstetric service, giving the patient's name and address and the nature of the emergency. The emergency unit, consisting of an obstetric surgeon, a midwife and the appropriate equipment, will be sent as speedily as possible to the patient's house. Should blood transfusion be necessary a supply of stored blood will be readily obtained from the council's hospitals. Midwives have the right to call out the emergency service only if they find it impossible to obtain a physician and they find the emergency grave. The local borough council will be responsible to the obstetric surgeon for an inclusive fee of \$26 for patients who cannot afford to pay his ordinary fee but reserves the right to ask the patient's husband to contribute a portion or the whole.

### Immunity in Venereal Lymphogranuloma

A contribution to the study of immunity possessed by different tissues toward the virus of venereal lymphogranuloma was presented by Dr Daminopetros of the Pasteur Institute of Athens at the January 24 meeting of the Académie de médecine de Paris. The author found that in venereal lymphogranuloma each receptive tissue has specific reactive powers which determine the character and evolution of the infection. This explains why involvement of the inguinal lymph nodes will heal in from six to eight months, whereas not only will proctitis persist for a much longer time but its evolution is much slower. A specific immunity of the female genital tract is the reason why localization there is comparatively rare in spite of a prolonged sojourn of the virus in the body. The systemic immunity following an involvement of the inguinal lymph nodes or of the rectum has no influence on the local lesions. This systemic immunity, as is shown by the cutaneous allergic reaction and the resistance of other potentially receptive tissues, is due to the direct action of the virus circulating in the blood. A virus the activity of which has been destroyed by the antigen injected subcutaneously or intravenously several times a week over a long period will not give rise to the general refractory state or the allergic cutaneous reaction and cannot protect the organism against an experimental infection.

The neutralizing products of the virus which circulate in the blood have a low threshold both in cases of proctitis and in cases of lymph node involvement when either the virus or the antigen is injected. Seroflocculation is distinctly positive only during the height of the inguinal infection. The serum of convalescents when injected subcutaneously and intraperitoneally into guinea pigs does not possess any preventive action toward an experimental infection. The injection of such serum subcutaneously, intravenously or even into infected areas appears to have no influence on the evolution of proctitis or lymph node involvement. On the other hand, the injection of the antigen into the infected tissues in cases of proctitis or lymph node involvement has a distinct curative influence and hence can be utilized in treatment. The author believes that the difference in the receptivity of various tissues is probably true for all types of infections.

### Multiple Electro-Encephalogram for Normal Persons

Prof Hans Berger of Jena read a paper at the International Psychologic Congress in Paris in 1937 in which he reported observations that only a single electro-encephalogram existed for the entire brain. This would mean that the bio-electric activity is the same in all parts of the cortex. At the January 24 meeting of the Académie de médecine de Paris, Prof A. Baudouin and his co-workers presented a paper in which their study of the question failed to corroborate the observa-

tions of Berger. They explored simultaneously two or three cerebral regions with the aid of the same number of amplifiers connected with a corresponding number of oscillographs. In the majority of the experiments the activities of the precentral and occipital regions were found to be independent, even though the two regions are the seat of alpha waves which coincide occasionally. Homologous regions of the two hemispheres may give rise to tracings which resemble one another but are without total concordance in the time of acceleration of alpha waves. Synchronism of the waves is noted for only short periods in triple electro-encephalograms (three recordings at three points of a hemisphere). The conclusion which can be drawn from these observations is that all cortical nerve areas have their independent electrical activities but that the latter are more or less coordinated. The frequency of cortical waves increases from a state of inhibition to one of activity in passing a state of physiologic rest.

### Certain Monkeys and the Influenza Virus

Various investigators have found that the ferret, mouse, rabbit, rat, guinea pig, hog and hedgehog are susceptible to the virus of influenza. At the January 24 meeting of the Académie de médecine de Paris Professor Levaditi reported the research of Dr Jean Vieuchange on inoculation of certain species of monkeys with the virus of influenza. This study was made before the author was aware of similar investigations by Dochez and his co-workers and by McIntosh and Selbie.

Although the experiments made by Vieuchange have not definitely solved the problem, the concordance of results permitted the following conclusions:

- 1 Inoculation of *Macacus rhesus* by the nasal route with the virus of influenza (human strain W S passed through the ferret and mouse) is followed by clinical and radiologic signs which indicate a generalized infection and a simultaneous pulmonary localization.

- 2 The saliva is virulent during the course of an experimental influenzal infection. There is also an invasion of the blood stream. It was possible to find the virus in the blood in one experiment on the seventh and sixteenth days after inoculation.

- 3 The animal serum acquires a marked neutralizing power toward the influenza virus.

- 4 If no clinical or radiologic signs are found after inoculation, it is justifiable to speak of a nonapparent infection, because the virus can be found in the saliva and blood of the monkey during the first few days. In one animal, which showed no signs of reaction after two inoculations, neutralizing properties were demonstrable in the serum.

### Program of Psychiatric and Neurologic Congress

The forty-third congress of the French Psychiatric and Neurologic Society will be held at Montpellier, in southern France, September 21-26. The president is Prof Henri Roger of Marseilles and the vice president Dr A. Porot of Algiers. The questions selected for special discussion are mental anorexias, immediate and late neurologic and psychiatric sequels of head injuries and follow-up studies of the criminal insane and of delinquents. Information with regard to the meeting can be obtained by writing to Prof P. Combemale, route d'Ypres, Bailleul, Nord.

### Election of Fellows in Académie de Médecine

At a recent meeting of the Académie de médecine, the leading medical society here, Dr Philip Pagniez of Paris was elected a fellow. Drs Castex of Buenos Aires, Argentina, and Nolf of Brussels were elected foreign associates. Dr Pagniez is attending physician to the public hospitals of Paris and has made important contributions to the study of epilepsy.

## Statistics on Epidemic Encephalitis

Dr Nagel of the psychiatric clinic of Munich University has compiled comprehensive statistics relative to 362 patients admitted there during the years 1917-1937 with a diagnosis of epidemic encephalitis or a condition simulating this disease. Even without including the patients who were merely examined at the clinic, there were 63.5 per cent of males and 36.5 per cent of females. Cases of acute involvement exhibited a peak in 1918-1919, a second and highest peak in 1920 and a smaller peak in 1923. The months of greatest morbidity were January, February and March. Study of the distribution according to age showed persons in the second and third decades to be most often severely affected (34.6 per cent and 33.2 per cent, respectively). The mean age of the male patients was 23 and of the female patients 23½. With regard to the symptoms, this survey contributed nothing essentially new. It is noteworthy, however, that nearly one half of the patients suffering from the sequels of epidemic encephalitis were unaware that they had experienced a disease of this nature, and 14 per cent of the erstwhile patients could give no account of their illness. Furthermore, intercurrent illness was shown to be exacerbated by parkinsonism, in 36 per cent of the cases no interval was discernible between acute illness and the parkinsonian syndrome. At the time of release from the hospital, 76 per cent of the patients had to be classed as unfit for work, 21 per cent were transferred directly from the clinic to other institutions.

## Medical Problems in the Substratosphere

The substratosphere was recently discussed before the Berlin Medical Society by Professor Strughold, who holds a special commission as instructor in air medicine. Recent records for altitude (around 17,000 meters) attained by fliers were made possible by the respiration of oxygen and the wearing of clothing designed to counteract excessive pressure. Even altitudes reached in ordinary flight (from 6,000 to 10,000 meters) are important. The changes produced in bodily function by ascent to high altitudes make their clearest imprint on the reflex action, this has been proved by experimentation in the low-pressure chamber. The effect of altitude was observed to progress according to definite stages. The first manifestation is a weakening of the reflexes, this sets in simultaneously with compensatory action of the respiration and circulation after transgression of the threshold of reaction. After the threshold of disturbance has been passed the efforts of the organism to aid itself become inadequate and an exaggeration of reflexes ensues. At this stage respiration of oxygen is unqualifiedly necessary. After passage of a critical threshold the exacerbation of reflexes leads to altitude cramps, which, apart from central influences, are to be interpreted as disturbances of the normal reflexes. At this stage all manifestations are nullified by respiration of oxygen. First after the lethal threshold has been passed do the cramps reach an irremediable state, which is followed by altitude death. If at a certain level the respiration of oxygen was suspended, all the foregoing states were exactly recapitulated as in actual ascent. The time elapsing from the interruption of the oxygen till arrival at the threshold of disturbance is the time reserve, this is dependent on the altitude attained and on the work performed and it presents great individual differences. However, the time reserve of the experimental human subject apart from slight variations is mostly a constant value. Only after performance of work does it tend to diminish. In parachute jumping from great heights a knowledge of the concept of

time reserve is particularly necessary. Otherwise, as often happens, the parachute is unfolded at too great an altitude and the jumper does not reach the levels of more abundant oxygen until a period far in excess of his time reserve has elapsed. Accordingly it seems expedient that the flier who jumps from great altitudes should open his parachute first at a level in which oxygen is abundant. Thus he will be able to traverse the dangerously high levels at a greater velocity and within a period well under his time reserve.

## Misuse of Boric Acid and Iodine

Acting on orders from the reichspräsident, the national minister of the interior has issued two warnings for the protection of public health. The first has to do with the use of purgatives containing boric acid. Medicaments which contain boric acid either free or in compound ought not to be taken except under medical supervision. Boric acid and its compounds, which after repeated ingestion tend to accumulate within the organism because of their slow excretion, are by no means innocuous if ingested in quantities of more than a few fractions of a gram. Preparations containing boric acid together with urea or dextrose are no exception.

Secondly, the minister warned the public against the indiscriminate use of iodized foods and medicaments that contain iodine. Iodine and its compounds, even if consumed in minute quantities, can lead, in persons sensitive to iodine, to more or less serious disturbances of thyroid activity, with the usual consequences. Iodine and its compounds are present in many pharmaceuticals recommended for infirmities of age and arteriosclerosis, for example such products as iodized bonbons, bath accessories of many sorts and cosmetics. Other iodine-containing products are recommended for the prophylaxis of colds, and there are iodized foods, iodized salt for example, which is of definite importance in the prophylaxis of goiter where the disease is endemic. Unfortunately the minister made no mention of iodized tooth pastes. These dentifrices, so abundantly and altogether irrationally advertised to the German public represent a menace to public health, since it is impossible for the user to know the amount of iodine absorbed each day.

## Marriages

WILLIAM NELSON DONOVAN, Memphis, Tenn., to Miss Josephine Catherine Devigne of New York, January 14.

JOHN J. KOBES, Kearny, N. J., to Miss Mary C. Mullan of Buffalo, at Montreal, Que., Canada, Nov. 3, 1938.

WARREN CANDLER BAILEY, Milledgeville, Ga., to Miss Virginia Anne Holder at Jefferson, February 14.

HUGH FARRAR RIVES, Pine Bluff, Ark., to Miss Frances Corbett of Springfield, S. C., February 1.

REGINALD HENRY MITCHELL, Washington, D. C., to Miss Katherine Palmer Foote Dec. 11, 1938.

ARTHUR J. CATES, Knoxville, Tenn., to Miss Katherine Rhodes of Bristol, Va., Nov. 26, 1938.

ROLLIN A. DANIEL, JR., Old Hickory, Tenn., to Miss Ann Kelley of Whitesville, Ky., January 5.

JOHN HUIT DELLINGER to Miss Ann A. Gaujot, both of Pennington Gap, Va., Dec. 26, 1938.

ROBERT D. DRIPPS, JR., Philadelphia, to Miss Diana Rogers of New Castle, Del., February 11.

SIDNEY M. RECKLER, Denver, to Miss Sarah Carol Redman of Houston, Texas, February 24.

J. KELVIN BLEICH to Miss Carol Marjorie Rosenberg, both of Atlanta, Ga., March 11.

JAMES HARRIS DEW to Miss Martha W. Carmichael, both of Atlanta, Ga., February 18.

ROBERT CARTER DAVIS to Miss Hilda B. Brown, both of Atlanta, Ga., February 4.

MEYER VITSKY to Miss Sara Strauss, both of Richmond, Va., Dec. 27, 1938.

## Deaths

**Walter Hamilton Snyder** ☉ Toledo, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891 in 1905 member of the House of Delegates of the American Medical Association, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, past president of the Toledo Academy of Medicine and Ohio State Medical Association, for many years president of the board of the Ohio Commission for the Blind, on the staffs of the Flower Hospital and the Lucas County Hospital, aged 68, died, Dec 29, 1938, of cardiac hypertrophy

**Beverley Randolph Kennon** ☉ Norfolk, Va., University of Virginia Department of Medicine, Charlottesville, 1893, past president of the Norfolk County Medical Society, member of the American Laryngological, Rhinological and Otolological Society, American Ophthalmological Society and the American Otolological Society, fellow of the American College of Surgeons, served during the World War, served at various times and capacities on the staffs of the Norfolk Protestant Hospital, Leigh Memorial Hospital, Norfolk General Hospital and St Vincent's Hospital, aged 67, died, Dec 27 1938, of coronary thrombosis

**John White McCammon** ☉ Cincinnati, Western Reserve University School of Medicine, Cleveland 1921, assistant professor of orthopedic surgery, University of Cincinnati College of Medicine, member of the Clinical Orthopedic Society and the American Academy of Orthopedic Surgeons, fellow of the American College of Surgeons, served in various capacities on the staffs of the Cincinnati General Hospital Jewish Hospital, Hamilton County Tuberculosis Sanatorium, Children's Hospital, Christ Hospital and the Cincinnati School for Crippled Children, aged 44, died, Dec 30, 1938, of acute coronary thrombosis

**Albert George Kern** ☉ Knoxville, Tenn., University of Pennsylvania Department of Medicine Philadelphia, 1901, member of the Southeastern Surgical Congress fellow of the American College of Surgeons, visiting surgeon to the Knoxville General Hospital Fort Sanders Hospital and St Mary's Memorial Hospital aged 63 died, Dec 5, 1938 in the New England Baptist Hospital, Boston of megacolon and acute gastric ulcer

**Maurice Joseph Sittenfield** ☉ New York, Bellevue Hospital Medical College, New York 1898 member of the American Association of Pathologists and Bacteriologists Radiological Society of North America, American College of Radiology and the American Radium Society, instructor in pathology, Columbia University College of Physicians and Surgeons, New York 1913 1920 and associate in pathology, 1920 1932 aged 61, died Dec 1, 1938

**Jonathan Harvey Winterbotham** ☉ Salina, Kan., Rush Medical College, Chicago, 1896 past president of the Saline County Medical Society, formerly county health officer and member of the state board of health, on the staffs of Asbury Protestant Hospital and St John's Hospital, aged 65 died, Nov 27, 1938, of cerebral arteriosclerosis

**William Franklin Shumaker**, Butler, Ind., Starling Medical College, Columbus, 1890, member of the Indiana State Medical Association, formerly county health officer and health officer of Butler, aged 73 died Dec 2, 1938, in the Sacred Heart Hospital, Garrett, following an operation for tuberculosis of the intestine

**James C Stewart**, Anna, Ill., St Louis College of Physicians and Surgeons, 1891, member of the Illinois State Medical Society and the American Psychiatric Association, formerly managing officer of the Alton (Ill.) State Hospital, aged 72, died, Dec 2 1938, of cerebral hemorrhage

**Carl Gay Davis** ☉ Hot Springs National Park, Ark., University of Arkansas School of Medicine Little Rock 1934, director of the clinic, U S Public Health Service, served during the World War aged 52, died Dec 3, 1938, in the Veterans Administration Facility, Fayetteville

**French S Holsberry**, Parsons, W Va University of the South Medical Department, Sewanee, Tenn., 1899, member of the West Virginia State Medical Association, formerly member of the board of education and county health officer, aged 66, died, Dec 3, 1938

**William Hermon Ballard**, New York, Memphis (Tenn) Hospital Medical College, 1910, served during the World War, acting assistant surgeon, U S Public Health Service, aged 52, died Nov 7, 1938, of heart disease following an operation for perirectal abscess

**Jennie May Coleman**, Des Moines, Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City, 1898, member of the Iowa State Medical Society, aged 70, died, Dec 3, 1938, at the Iowa Methodist Hospital of diabetes mellitus

**Herbert Emil Koepke** ☉ Cadiz, Ohio, State University of Iowa College of Medicine, Iowa City, 1928, county health officer, aged 40, died, Dec 18 1938, in the Ohio Valley General Hospital, Wheeling, W Va, of uremia

**Jesse Cunningham Stille**, Ludlow, Pa., University of Maryland School of Medicine, Baltimore, 1912, member of the Medical Society of the State of Pennsylvania, served during the World War, aged 55, died, Nov 26, 1938

### THE POTENCY OF DIGITALIS STANDARDIZED ACCORDING TO U S P XI

To the Editor—There appears to be a growing confusion among physicians and others with regard to the changed relationships in the standardization and dosages of digitalis preparations made according to the requirements of U S P XI as compared with those of U S P X.

All U S P digitalis preparations manufactured prior to June 1, 1936, were standardized according to U S P X. Practically all clinical articles published between 1926 and 1938 are based on the administration of U S P X standardized digitalis. U S P X required all official digitalis preparations to be standardized on frogs by the one hour progressive dose method and to be adjusted to a toxicity of 0.006 cc (range 0.0055–0.0065 cc) of tincture per gram of frog or, in everyday language, the equivalent of 600 mg (range 550–650 mg) of standard digitalis leaf per kilogram of frog.

Digitalis preparations manufactured and standardized since June 1936 have been standardized according to the requirements of U S P XI.

These requirements are essentially that the preparation shall be standardized by the one hour progressive dose frog method to a toxicity equal to that of a tincture freshly made from the U S P reference standard digitalis powder. This reference powder in some twenty standardizations made personally in this laboratory in the past two and a half years has shown a mean toxicity of 350 mg per kilogram of frog by the official (U S P) one hour frog method.

What many physicians do not seem to recognize is that the digitalis preparations which they are now using have been standardized according to the requirement of U S P XI and are approximately 70 per cent stronger than were those which they have been accustomed to use for the past ten or twelve years and that the actual dosage of U S P digitalis preparations which they administer to their patients, either for digitalization or for maintenance, must be reduced to at least two thirds of the amount they have been previously accustomed to use. Unless this is done they will encounter frequent instances of digitalis overdosage—nausea, vomiting, excessively slow heart, ventricular extrasystoles, and the like—which will impair the efficiency of the heart.

Although never an official method, considerable standardization of unofficial digitalis preparations has been made in the past with the Hatcher-Brody cat method.

Comparative standardization of official (U S P) frog standardized digitalis preparations standardized according to U S P X (1926–1936) by the Hatcher-Brody cat method, showed that 1 cc of a U S P X tincture was approximately equal to 1 Hatcher-Brody cat unit.

Many clinicians thus developed the habit during the first ten to twenty years of transposing cubic centimeters of frog standardized tincture of digitalis directly to cat units and of controlling their dosage to patients in terms of cat units.

But since U S P XI tincture of digitalis is approximately 70 per cent stronger than the U S P X tincture was, the amount of digitalis activity commonly referred to as a cat unit (Hatcher-Brody) is now contained in 0.60–0.65 cc of a U S P XI standardized tincture or from 60 to 65 mg (1 gram) of powdered digitalis. Attention to this fact has recently been drawn by Fahr (*THE JOURNAL*, Dec 17, 1938, p 2269, footnote 5).

The situation is further complicated by the fact that both the U S P reference standard powder and the international reference standard powder, on which the U S P powder is based, were standardized by a modified cat method developed by Magnus and Van Wyngaarden which, through the use of arti-

ficial respiration and the like, enables the cat to tolerate a very much larger dose of digitalis than is possible by the original Hatcher-Brody method.

Edmunds, Moyer and Shaw (*J Am Pharm A* 26 290 [April] 1937), who standardized the U S P XI reference standard powder for the U S P Revision Committee, employed two types of standardization, (1) on frogs by several methods and (2) on cats by the Magnus-Van Wyngaarden method (Krafft-Lenz, *E J Pharmacol & Exper Therap* 29 407 [Oct] 1926; Van Wyngaarden *Arch f exp Path u Pharmacol* 112 252, 113 40, 1926). Edmunds and his associates found a toxicity by the one hour frog method of 391 mg per kilogram of frog and by the Magnus cat method that 1 cc of the reference standard tincture was approximately equal to 1 Magnus cat unit.

Failure on the part of clinicians and pharmaceutical manufacturers to keep clear the considerable difference between the amount of digitalis activity represented by the two cat units is responsible for much of the existing confusion.

Another factor in the confusion is that few, if any, of the manufacturers of unofficial digitalis preparations (which are not legally required to be standardized by the U S P frog method) use either the original Hatcher method or the later Magnus method but have adopted a modification of their own.

The approximate relationships which exist between the various units may, therefore, be summarized as follows:

- 1 U S P XI digitalis unit
  - = 0.1 Gm U S P XI digitalis powder
  - = 1.0 cc U S P XI tincture of digitalis
  - = 0.17 Gm U S P X digitalis powder
  - = 1.7 cc U S P X tincture of digitalis
  - = 1.7 cat units if determined by the Hatcher method the widely known clinically used cat unit
  - = 1.0 cat unit if determined by the Magnus method the little known international (League of Nations) cat unit

HAROLD N. WRIGHT, PH D, Minneapolis

Assistant Professor of Pharmacology,  
University of Minnesota Medical  
School

To the Editor—In footnote 5 of a recent article in *THE JOURNAL*, page 2269, I state "At present digitalis is standardized according to the U S P XI so that 0.65 cc of the tincture or 0.065 Gm (1 grain) of the powdered leaf is [equivalent to] 1 Hatcher-Brody cat unit. In the previous editions of the U S Pharmacopoeia, 1 cc of tincture or 0.1 Gm of the powdered leaf contained 1 cat unit. One tenth Gm (1½ grains) of the standard U S P XI powder is equivalent to 16 Hatcher-Brody cat unit." This statement has occasioned considerable confusion among both physicians and pharmacologists, as attested by letters which I have received after publication of this paper. The statement, therefore, needs some clarification.

I know of a number of cases of digitalis overdosage resulting from the fact that the attending physician prescribed digitalis that had been standardized in accordance with the directions of the U S P XI as if the drug had the same potency as digitalis standardized according to the directions of the U S P X. Most interesting of all is the fact that one pharmacologist overdigitalized himself with a U S P XI preparation, not knowing that he was using a digitalis from 50 to 60 per cent more powerful than the U S P X digitalis which he had been using for years. I am sure that many physicians have been spared overdigitalizing their patients because few pharmaceutical houses are as yet putting out digitalis standardized according to the U S P XI. Most pharmaceutical houses are still putting out digitalis standardized according to the U S P X. It is therefore imperative that physicians be warned that there are now two kinds of digitalis available in the drugstores. Most of it is standardized according to the U S P X, in which case approximately 100 mg (1½ grains) of powdered leaf to

10 pounds of body weight will accomplish nearly complete digitalization if given over a short period of time, i. e. from twenty-four to forty-eight hours. There are at the same time other preparations standardized according to the U S P XI. The latter preparations have a potency such that 65 mg (1 grain) of powdered leaf to 10 pounds of body weight will accomplish nearly complete digitalization.

The tenth Pharmacopoeia of the United States gives the following directions for standardizing digitalis: "Digitalis, in the form of tincture properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (the minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.006 cc of tincture for each gram of body weight of frog." The XI Pharmacopoeia prescribes the following: "The potency of digitalis shall be such that 0.1 Gm of it when assayed as directed shall possess an activity equivalent to not less than 1 U S P digitalis unit." In order to compare the potency of the two preparations it is necessary only to learn what is meant by 1 U S P digitalis unit.

In 1936 it was determined that a new standard for digitalis preparations was to be set up in conformity with the international or League of Nations digitalis standard. A so-called reference powder was then made up, and this reference powder is given to any authorized person who wishes to standardize digitalis preparations. Edmunds (*J Am Pharm* 1 26 290 [April 1937]) has standardized the U S P XI reference powder, using two methods. Using the so-called one-hour frog method, he finds that 0.000391 Gm of the powdered leaf per gram of frog stops the heart in systole in one hour. Making use of the Magnus cat method he finds that 1 cc of the standard reference tincture equals approximately 1 Magnus cat unit. It is now clear that the U S P XI standard reference powder has such a potency that 0.000391 Gm per gram of frog stops the heart within one hour, whereas U S P X required that 0.0006 Gm of digitalis per gram of frog stop the heart in one hour. In other words the potency of the U S P X official digitalis is 65 per cent of that of the U S P XI.

Many observers had noted that the U S P X digitalis had a standardization value of 100 mg equivalent to 1 original Hatcher-Brody cat unit. It is therefore desirable to know the relationship between the Hatcher-Brody and the Magnus or international cat unit. Approximately 16 Hatcher-Brody units equals 1 Magnus cat unit. Again we see that, standardized on cats, the digitalis prescribed by the tenth Pharmacopoeia is 63 per cent as strong as the digitalis prescribed by the eleventh Pharmacopoeia.

For the practicing physician, this means that in cases in which he had been using or is using 100 mg (1½ grains) of digitalis leaf or 1 cc of tincture standardized according to the tenth Pharmacopoeia he should prescribe 0.065 Gm (1 grain) of powdered leaf or 0.65 cc of tincture when using a digitalis preparation standardized according to the U S P XI.

GEORGE FAHR, M D Minneapolis  
University of Minnesota Medical School

To the Editor—The confusion concerning digitalis standardization is illustrated by a comparison of the opinions of two eminent authorities printed within a period of three weeks in THE JOURNAL.

On Dec 17, 1938, in "The Treatment of Cardiac Irregularities" George Fahr (page 2269, footnote 5) states: "At present digitalis is standardized according to the U S P XI so that 0.65 cc of the tincture or 0.065 Gm (1 grain) of the powdered leaf is 1 Hatcher-Brody cat unit. In the previous editions of the U S Pharmacopoeia 1 cc of tincture or 0.1 Gm of the powdered leaf contained 1 cat unit. One-tenth gram (1½ grains) of the standard U S P XI powder is equivalent to 16 Hatcher-Brody cat unit."

On January 7, in "Drug Therapy in Coronary Disease" Harry Gold (page 5) states: "A satisfactory dosage in the average case of auricular fibrillation or heart failure in coronary thrombosis is about 6 grains or 0.4 Gm (4 cat units) of digitalis leaf daily for three days." This implies that powdered digitalis assays 1½ grains to the cat unit.

The U S Pharmacopoeia, pages 397-398, makes no mention whatever of standardization of digitalis by the Hatcher-Brody or any other cat unit method. Supposedly digitalis is assayed by the frog method, the U S P reference digitalis powder (U S P, p 485) being used as a standard. Reference powder is supposedly equivalent to the international standard digitalis powder, of which 0.1 Gm is 1 international digitalis unit. That this ideal is not accomplished in practice is evident from the studies of Edmunds Moyer and Shaw (*J Am Pharm* A 26 290 [April 1937]) and Rowe and Pfeifle (*ibid* 27 182 [March] 1938). After having investigated many commercial products, these authors have arrived at quite different conclusions concerning the comparative potency of the commercial preparations, the U S Pharmacopoeial standard and the international standard powder. The latter authors conclude that the U S P XI standard is 150 per cent of the U S P X potency and 125 per cent of the international standard potency. The various digitalis products on the market seem to differ widely from one another as well as from the reference standards.

It seems evident that the problem is worthy of thorough elucidation, particularly since there seems to be no reference to the subject in the recent medical literature. Whatever data are available were found in the pharmacy publications.

Until the standard of potency is more satisfactorily established, it seems quite clear that the clinician must depend on presumably equal potency of the same manufacturer's product. So wide a variation in potency as 35 per cent between different preparations makes it urgent that each patient be advised to continue the use of a certain brand of digitalis throughout the period of therapy. Even preparations dispensed in cat unit dosage are not interchangeable, since cat unit values have been found to be duplicable only in the hands of the same assayer, if at all.

LEON LEWIS, M D, Newark, N J

## INVESTIGATIONS ON ANTIBODIES

To the Editor—What does the writer of the editorial mean when he says in "Recent Investigations on Antibodies" (THE JOURNAL, February 25, p 735): "The investigators, however, have for the first time applied quantitative immunochemical techniques to the problem of splenic immunity"? Does he not consider the techniques of Hektoen and Carlson quantitative or my work using such methods, qualitative? Has he seen my "A Study of the Origin of the Immune Bodies by the Method of Organ Transplantation" (*Proc Soc Exptl Biol & Med* 7 122-124, 1910)? Or more to the point, because more physiologic, has the writer of the editorial read the work (confirmed later by Preston Kjes using intermediate dilutions) entitled "The Relation of the Spleen to the Fixation of Antigens and the Production of Immune Bodies" by Luckhardt and Becht, *Am J Physiol* 28 257-274 [Aug 1] 1911)?

In these papers the spleen is shown to be related specifically with the formation of immune bodies (antigen used: goats corpuscles for hemolysins, hemagglutinins and hemopsonins, rats corpuscles for hemagglutinins and hemopsonins) but not exclusively so, since "asplenic dogs do not produce hemolysins hemagglutinins or hemopsonins (a) as rapidly nor (b) in as high a concentration as the corresponding control dogs." Since even asplenic dogs showed an immunity curve why make the statement "Possibly these investigations will lead to the recrudescence of interest in the supposedly obsolete hypothesis which pictured the spleen as the sole source of specific antibodies"? One would have to go back pretty far and brush aside a good

deal of evidence is inconsequential to find some one defending the hypothesis that the spleen was the "sole source of specific antibodies."

Some of the drug action referred to in this editorial can be readily explained on the basis of present day knowledge of splenic function. I would not say that it was all due to constriction and dilation of the spleen, but with the available evidence I would be inclined to think so and would mention this possibility rather than write that it was due to the "therapeutic stimulation of the parasympathetic." As a matter of fact, if the writer of the editorial and the investigators quoted had read the brief article in the *American Journal of Physiology*, Proceedings of the American Physiological Society, Baltimore, March 30, 31, April 1 and 2, 1938, pages 159-160, by J. Maurice J. Palitz (now in preparation for complete publication), the interpretations in my mind would certainly have occurred to them. As a matter of fact, a previously published abstract (*Am J Physiol* 116:118 [June] 1936) would have suggested it. With these data in mind the writer would, I believe, have written the editorial entirely differently. At present it has a flavor of occultism.

ARNO B. LUCKHARDT, M.D., Chicago

Department of Physiology, University of Chicago

### SULFAPYRIDINE IN PNEUMONIA

*To the Editor*—We have read with interest the instructive article on the treatment of pneumonia with sulfapyridine by Dr. Harrison F. Flippin and his associates (*THE JOURNAL*, February 11, p. 529).

The wide variation in free blood sulfapyridine observed by Flippin may be accounted for on one or more of at least three grounds: (a) variability in the time at which blood samples were taken in relation to drug dosage, (b) coincidental renal impairment of function and (c) individual variability in conjugation of the drug in the blood stream.

In December 1938 certain experiments were performed in our laboratories at Cold Spring Harbor which showed clearly the extreme variability in man of conjugation of sulfapyridine especially as it appears in the urine eighteen hours after the administration of a single 3 Gm. dose by mouth. Superficially there appeared no explanation for this result, since both subjects were normal men. One of us (D. A. B.) suggested, however, that the result might conceivably be due to differences in the basal metabolic rate; it was found on investigation that this hypothesis fitted the facts. The man in whom maximum conjugation occurred has a basal metabolic rate of  $\pm 30$ , the man in whom the least conjugation occurred having a subnormal basal metabolic rate. In these men the one with the higher metabolic rate excreted approximately 90 per cent of the material in conjugated form, whereas the one with the low metabolic rate excreted approximately 50 per cent of the material in conjugated form.

One of us (D. R. C.) then carried out an experiment at Cold Spring Harbor to determine whether or not this apparent effect of the metabolic rate could be confirmed in small animals. Nine rabbits were divided into three groups. The first of these groups (three rabbits) received a dose of 2,000 mg. per kilogram of the free acid in water suspension. The second group (three rabbits) received 2,000 mg. per kilogram of the free acid in water suspension after a preliminary intramuscular injection of 20 mg. per kilogram of sodium dinitrophenol. The third group (three rabbits) received 2,000 mg. per kilogram of the free acid in water suspension after the intravenous administration of an anesthetic dose of cycloidal soluble. The first group showed the usual blood concentration curves. The second group showed a hyperpyrexia and a significant increase in the ratio of conjugated to total sulfapyridine in the peripheral circulation. The third group did not show any significant change from normal.

We believe that this sheds some light on the apparent discrepancies between the blood levels and the therapeutic effectiveness. Further observations by clinicians and those to be published from our own laboratories will undoubtedly clarify the matter.

### WRITING PRESCRIPTIONS FOR NARCOTICS

*To the Editor*—As a subscriber to *THE JOURNAL*, I should like to call attention to a matter which is causing me and many other careful pharmacists, I know, many a "headache." That is the careless way in which most physicians write prescriptions for narcotics. There is scarcely a prescription offered for compounding in my prescription department that is 100 per cent properly written. Most of them fail in at least two or three points. The name is often not properly written, the age is seldom given, and the physician's signature is often not properly signed.

To me this is an important point in the writing of narcotic prescriptions, and I believe that you would confer an important favor to both physicians and pharmacists by calling attention to this matter.

Following is the text of a circular issued by the Kings County Pharmaceutical Society.

#### NARCOTIC PRESCRIPTION REGULATIONS

- 1—Must be written in ink or indelible lead.
- 2—The full signature of the physician, as well as address and registry number, are required.
- 3—Name, address and age of patient (child, adult, etc., is not sufficient).
- 4—If the amount of narcotic prescribed is for an unusual quantity the disease must be indicated or the following designations may be used, Article 117, Exemption 1 (meaning, for an incurable disease), or Article 117, Exemption 2 (meaning, for an inborn patient).
- 5—The pharmacist may supply the physician with one ounce of an aqueous solution of a narcotic not over 10% strength, for his office use, provided the order is written on an official federal order blank.
- 6—The pharmacist may renew a prescription containing the exempt quantities of a narcotic, which are as follows: not more than 2 grains of Opium, 1 grain of Codeine and  $\frac{1}{4}$  grain of Morphine to the ounce.
- 7—A prescription for narcotics cannot be renewed on a physician's order to "Renew" nor can a telephone order be accepted. A new prescription must always be written.

Both the physician and the pharmacist are liable for any violation of the above mentioned rules.

For the protection of the patient, as well as the doctor and the pharmacist, we would suggest that the age of the patient be stated on all prescriptions whether or not for narcotics. Also that the directions be written on every prescription whether for internal or external use.

### PERIPHERAL VASCULAR DISEASE

*To the Editor*—In *THE JOURNAL* January 21, page 230, Ochsner and DeBailey discuss "The Rational Consideration of Peripheral Vascular Disease." This is an excellent study but should include the use of roentgen rays in the treatment of vasospastic conditions such as Raynaud's disease. According to some observers this method is of doubtful value, but according to others the same may be said of some of the methods described in this article. Those who have had greater experience in the use of roentgen rays for circulatory disturbances consider this a valuable modality in thromboangiitis obliterans particularly, and also in Raynaud's disease. A paper as exhaustive as this one, in my opinion, should have included a discussion of this form of treatment.

ABRAHAM S. ROTHEIMER, M.D., New York

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### FURUNCULOSIS IN SHIFT METAL WORKERS

To the Editor—A white man aged 46, a sheet metal worker, has suffered from furunculosis since Sept. 18, 1938. For the most part the location of the furuncles has been limited to the upper extremities and the axillary regions. In addition, a widespread eczematoid dermatitis developed following the use of Neko soap. The latter condition has proved troublesome since the skin is now sensitive to many of the topical applications I had been using in the local treatment of the furuncles. The usual response to these applications is that of vesiculation. Among the chief offenders in this respect are ointments or solutions containing mercury, phenol and magnesium sulfate. The patient's general physical condition is good and outside of the conditions mentioned and a moderate hypotension there is nothing to note. Repeated examinations of the urine have been negative. The white blood cell count is slightly elevated but never has been higher than 14,000. The hemoglobin and the red blood cell count are within normal limits. The Kahn reaction is negative. In addition to the local treatment which consisted of incision and drainage when indicated, the use of boric acid compresses and magnesium sulfate compresses and various ointments, the patient has been given adequate amounts of cod liver oil, dicalcium phosphate, iron and copper, and vitamin B. About twenty injections of furunculosis vaccine have been given thus far according to the usual plan. Tinopronate Searle (metallic tin organically combined with a digestible protein base) was also tried but seemed to aggravate rather than benefit the condition. Kindly suggest treatment.

M D Illinois

ANSWER—Metal workers may be exposed to a variety of cutaneous irritants such as volatile solvents, antimony, arsenic, chromium, lime, soldering compounds, petroleum oil and grease. This query illustrates the difficulty encountered in offering advice about any industrial medical problem without precise knowledge of the materials or processes involved.

Furunculosis usually can be traced to petroleum oils, grease and tar, the sites of predilection being the arms and legs. Axillary involvement, therefore, is probably not of industrial origin unless it occurred by spread or secondary infection from the arms.

The exact composition of Neko soap is not known, but antiseptic soaps often contain mercury, phenols and benzoates, in themselves possible sources of dermatitis.

In addition to urinalysis, determinations of the blood sugar should be made, and if high levels are recorded appropriate treatment should be instituted. Local treatment should include incision and drainage together with the application of an antiseptic in proper dilution which has been found nonirritating by preliminary patch tests. A 2 per cent solution of formaldehyde or a 1 per cent solution of sodium benzoate may be useful. Autogenous vaccines are preferable.

If the patient does not respond to the treatments suggested, ultraviolet rays obtained from an alpine sun lamp or X-rays may be tried. Other methods of treatment suggested are colloidal manganese, recommended by Gardner; injections of 15 per cent rectified turpentine and 5 per cent ethyl aminobenzoate and quinine hydrochloride in olive oil, recommended by Levine and Rose; and autohemotherapy consisting of 10 cc of venous blood intramuscularly, recommended by Nicolas, Gate and Dupasquier.

### CALCIUM AND VITAMIN D IN DIET

To the Editor—A child about 3 years old showed improvement as a result of calcium therapy given concurrently with vitamin D preparations. Are there any indications for stopping the use of calcium while improvement in general health continues?

M D New Jersey

ANSWER—As the amounts of vitamin D and of calcium prescribed for the child are not stated and the indication for prescribing these substances have also been omitted, a specific answer to the question is not possible.

Calcium requirements for children have been investigated by Sherman (Chemistry of Foods and Nutrition, New York, Macmillan Company, 1927, p. 311; Sherman, H. C., and Hawley, E. Calcium and Phosphorus Metabolism in Childhood, *J Biol Chem* 53:375 [Aug.] 1922) and his results have been confirmed by others. Any child who is not allergic to milk should be able to ingest in his daily diet all the calcium that is needed to maintain health or to restore deficiencies in the bones or other parts of the organism. However, it is frequently difficult to supply adequate amounts of vitamin D

unless vitamin D supplements are used. The dosage of vitamin D should be limited to a reasonable therapeutic or prophylactic requirement. It is possible to create a toxic state from chronic overdosage of either calcium or vitamin D, and hypervitaminosis D is becoming recognized as a true clinical entity. Overdosage from calcium salts taken by mouth may produce gastrointestinal irritation evidenced by gastric distress, nausea, vomiting and diarrhea. The real dangers of calcium overdosage are those which result from prolonged hypercalcemia and these include a disturbance of conduction in the heart, ventricular fibrillation and tachycardia and, if serum calcium concentration is maintained at about 15 mg per hundred cubic centimeters in experimental animals, fatal results may be produced (Cantrow, Abraham, Calcium Metabolism and Calcium Therapy, Philadelphia, Lea & Febiger, 1931, pp. 135-137). Joseph Goisman and Edward L. Compere (The Healing of Fractures of Atrophic Bones, *J Bone & Joint Surg* 20:587 [July] 1938) found that fractures of bones in either young or old rats on mineral-deficient diets did not heal more promptly or more adequately when large amounts of vitamin D, of calcium or of both substances were added to the basic diets than did those in rats which had been on a normal basic diet previous to fracture; in some instances these supplements seemed to retard bone repair.

### CONGENITAL VARICOSITIES OF LEG

To the Editor—An obese woman aged 28 was born with an extreme varicose condition of the entire right leg up to her waist. Please give me the name of the best knit hose for her to wear and the company which makes them. The elastic hose that she has worn has been unsatisfactory. Would it be safe to operate on such an extensive involvement of veins?

M D Oklahoma

ANSWER—The description does not mention any change in the size or temperature of the affected right limb as compared with the other. However, it seems that this is a congenital vascular anomaly, which usually consists of multiple arteriovenous communications although occasionally a diffuse hemangioma may be present.

An elastic stocking made to order and reaching all the way to the groin may be obtained through any one of the surgical supply houses in larger cities. It may give some protection and subjective relief. However, an effort should be made to stop the progress of this vascular anomaly by surgical methods. This involves operations in multiple stages and should be undertaken only by men experienced in this type of surgery. Some of these patients unless actively treated develop an elephantiasis or because of the gradually diminishing circulation to the toes show gangrenous patches. If an arteriovenous communication is present, this may throw an increased load on the heart so that cardiac dilatation and even failure may result.

### LOCALIZED MELANOSIS AFTER IRRITATION

To the Editor—A boy 15 years old has several areas on the face about 1.5 cm in diameter which seem permanently discolored. This is the result of a practical joke last summer when at camp some other lads daubed his face with strong iodine. The areas are stained a dark brown and do not seem to fade. Is there any escharotic paste that could safely be used in the attempt to remove these blemishes or what could you suggest?

M D New York

ANSWER—A stain remaining for months after the application of tincture of iodine is due to increased production of melanin, iron free skin pigment, as a response to the irritation. Persons whose skin produces pigment readily are apt to have such mementos of various kinds of irritation. They occur frequently after the use of mustard plasters. During the relatively slight exposure to light during the winter months they will fade just as freckles do. If it is desirable to hasten this process, the time honored freckle lotion containing one part of mercury bichloride in 500 parts of 50 per cent alcohol may be dabbed on several times a day until an inflammatory reaction results, when the treatment is stopped and exfoliation awaited, which is expected to produce a blanching. From 5 to 20 per cent lactic acid in water may be used in the same way, but this is painted on at longer intervals with care to cover only the pigmented spot. Well adapted to small areas such as those described is the application of carbon dioxide snow for a few seconds under light pressure. Five seconds, even less in some cases, causes an exfoliation and this is the most easily controlled method, giving the quickest results. One application is made and the result awaited. If not sufficient to produce a reaction, a stronger application can be made a few days later.

A warning goes with advice such as this. There is always a risk that the irritation intended to remove the pigment will have the same result as that which caused it to occur.

### DETERIORATION OF MILD PROTEIN SILVER AND STRONG PROTEIN SILVER

*To the Editor*—In THE JOURNAL Oct 8 1938 page 1466 in a special article by Henry W E Walther on local urinary antiseptics under the discussion of silver preparations occurs the statement all these solutions should be made freshly every day or two since they deteriorate on standing and they should be kept in amber colored bottles Beckman in Treatment in General Practice in writing on the treatment of gonorrhea states It is popularly believed that they [strong protein silver and mild protein silver] both deteriorate rapidly That this is not true has recently been shown by Pilcher and Sollmann (1924), who found that (a) strong protein silver solutions become poorer in ionic silver and therefore less efficient but not sufficiently so to become of much clinical importance even in one year (b) Mild protein silver on the contrary becomes richer in silver ions and therefore more antiseptic but also more irritant The changes in mild protein silver solutions start rapidly so that a week might modify the clinical response How do you reconcile this difference of opinion among authorities? Who is right?

J A MILLSPAUGH MD San Pedro Calif

**ANSWER**—The difference of opinion arises probably from the use of different criteria Those of Pilcher and Sollmann were based on the checking of yeast fermentation, while those of Walther were based on clinical traditions, which it would be difficult to substantiate objectively However, there is no serious disagreement between the two statements as to mild protein silver This may become irritant inside of a week and progressively more so with time The difference in the statements as to strong protein silver solution is greater, but it would be difficult to judge decrease of antiseptic action clinically Perhaps the "caution" is based largely on the possibility of bacterial or mold infection of the solution with standing Exposure to light might also reduce the ionized silver to inactive forms

### CORNEAL GRATTS

*To the Editor*—Please advise whether there is a well authenticated case of transplantation of the cornea in which there was any vision two or three months following operation

A L COYLE MD Pittsburgh

**ANSWER**—There have been well authenticated cases in which a disk comprising the full thickness of the cornea, was transplanted with good vision for from three months to periods of more than one year after operation Publications by Castroviejo of New York, Filatov of Philadelphia and Elschmig of Prague, list many such cases Transplantations of the whole cornea, however, have not been successful and any form of transplantation is apt to be successful only when the entire cornea is opaque Apparently a portion of the clear cornea at the periphery is necessary for the persistence of a clear corneal graft

### TUBERCULOUS OSTEOMYELITIS OF STERNUM

*To the Editor*—About one year ago a friend of mine returned from a neighboring country where he had undergone a surgical operation consisting in the incision of an abscess located in the anterior chest wall at the junction of the plate and process of the sternum I found histologic as well as bacteriologic evidence of the tuberculous etiology of the lesion The roentgenograms showed a zone of rarefaction in the region mentioned Thereupon I indicated a treatment with iodized oil recalcification heliotherapy and cleansing of the wound surface The wound which at that time measured about 1 inch in diameter and presented some discharge closed following this treatment and cicatrized completely after seven months Contrary to my advice the patient took strenuous exercises with the upper extremities whereupon the wound reopened to an extent of 3 mm in diameter with slight uppuration closing sometimes and reopening again In despair he asks me to remove the bone focus As my experience is contrary to such a measure I would appreciate your opinion

JOSE PEREZ LORIE MD Habana Cuba

**ANSWER**—In tuberculosis of the bone in which secondary infection has not occurred, every effort should be made to secure healing by medicinal management without drainage of accumulated pus Once an abscess has been drained, secondary infection is almost certain to occur This complicates the picture seriously, converting the tuberculous osteomyelitis into a mixed infection osteomyelitis In such cases, especially in the ribs and sternum, it is necessary to excise the affected bone, pack the wound with antiseptic gauze and permit it to heal by granulation

In the case under consideration it is likely that surgical excision will eventually be necessary In this sort of lesion, recent communications have reported success from instillations of cod liver oil It might be well to try this treatment for several months before resorting to surgery

Osteomyelitis of the sternum is likely to be a difficult condition to treat surgically Being cancellous bone it presents the same problems as does osteomyelitis of the skull After one has apparently excised all infected tissue, the infection may spread in the cut surface of the bone, necessitating repeated operations and wider and wider excisions For this reason it

is advisable to be radical at the first operation, to remove the bone well beyond the infected area, to treat the cut bone edges with bismuth iodoform paste and in the postoperative period until the wound is well healed, to keep it thoroughly irrigated with diluted solution of sodium hypochlorite In several cases of this kind in which the infection continued to extend the maggot treatment has been used with some success Wide excision of bone and thorough antiseptics during the postoperative period are important factors in the surgical treatment

### TRIGEMINAL NEURALGIA

*To the Editor*—A white man aged 50 weighing 240 pounds (109 Kg) has been suffering from a trifacial neuritis for the past three years These areas are especially painful to touch so that even washing the face is a painful task I have used every method possible to find a focus of infection His sinuses and teeth are negative to x-ray examination but even so I have had him have the extraction of several suspicious teeth with an apparent slight temporary relief I have given him every medication possible including salicylates cinchophen and Oxotate B I have used all types of physical therapy, including short wave diathermy Triethyl chloride has been given as inhalations for pain but the only partial relief he gets is with soluble phenobarbital 1½ grains (0.1 Gm) by mouth Will you please suggest a cause some means of diagnosis and a treatment as the only other treatment I can think of is the injection of the ganglion.

MD Louisiana

**ANSWER**—According to the diagram sent by the inquirer the patient suffers from pain in the area of distribution of the ophthalmic and maxillary divisions of the right trigeminal nerve Because the pain does not cross the midline to the left side of the face, because of the initiation of pain by cutaneous stimulation and because foci of infection are not present about the head, the diagnosis of major trigeminal neuralgia (tic douloureux) is probably accurate It is not mentioned whether or not there are discrete dolorogenic zones which set up the pain when stimulated by touching or washing the face, nor is it stated whether there are signs of other cranial nerve involvement which would suggest the presence of a lesion of the paratrigeminal area The cause of trigeminal neuralgia is generally conceded to be unknown Permanently successful treatment consists of section of the trigeminal root proximal to the gasserian ganglion, by way of a subtemporal, extradural approach Alcohol injections offer uncertain and at the best only temporary relief from the pain of trigeminal neuralgia

### EXTREME LORDOSIS AND DELIVERY

*To the Editor*—What is the prospect of a normal delivery for a primipara aged 23 with a normal pelvic measurement but whose pelvis is tilted backward with an extreme lumbar lordosis and whose right thigh cannot be abducted or flexed at all?

MD Illinois

**ANSWER**—An accurate answer cannot be given from the information at hand Lumbar lordosis, depending on the degree, may cause changes in the pelvis resulting in increased pelvic inclination If the diseased vertebrae are the lowest lumbar, the inlet of the pelvis may be roofed over by the spinal column and the head cannot enter the inlet A decision can be reached only after thorough x-ray study Preparation for the delivery should include hospitalization It is possible that a test of labor will be advisable All plans should visualize a possible delivery by cesarean section

### THUMPING IN EARS

*To the Editor*—When I lie down in bed I can hear as my heart beats a constant regular thumping in both ears and can easily count the number of heart beats per minute by this It is quite disturbing to me. I can find nothing in my literature relative to this condition

MD Kentucky

**ANSWER**—In the absence of any organic disease such as hypertension, valvular cardiac disease or hyperthyroidism the awareness of the heart on lying down in a quiet room is of no great significance It occurs in many normal persons, especially those who are of the so called nervous disposition

### ANTERIOR PITUITARY LIKE SUBSTANCE AND HEART

*To the Editor*—Could the administration of antuitrin S to a boy of 10 years (adiposogenital dystrophy) have any possible deleterious effect on the heart?

MD Idaho

**ANSWER**—No investigative work has been found in the literature concerning the influence of anterior pituitary-like substance on the heart and no deleterious effect on the heart even when large doses have been continued for as long as a year have been noted It would appear that if reasonable dosage is administered no harmful effects on the heart will result

## Council on Medical Education and Hospitals

### ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Thirty-Fifth Annual Meeting held in Chicago Feb. 13 and 14, 1939

(Continued from page 1098)

DR. FRED MOORE, Des Moines, Iowa, in the Chair

### COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 13—AFTERNOON

### SYMPOSIUM ON THE SMALL HOSPITAL

#### The Community Hospital

MR. BARRY C. SMITH, New York. This paper will be published in full in THE JOURNAL.

#### The Small Hospital Organization and Management

DR. MALCOLM T. MACLEACHERN, Chicago. In the present discussion I shall mean by the small hospital one which cannot, for various reasons, supply within itself complete diagnostic and therapeutic facilities. Usually its bed capacity is less than fifty, but under some circumstances a hospital of seventy-five or a hundred beds may justly be placed in the small hospital class. Not many governmentally owned hospitals fall into this class. Occasionally a community may through its organized government build and maintain such a hospital but usually the small hospital is owned and operated by a church, a fraternal order or the community through some organization other than the community government and is spoken of as a voluntary hospital. Such institutions constitute a large percentage of all hospitals.

Good organization is as essential in a small hospital as in a large hospital. Many elements are involved, and the end result sought is the complete and efficient care of the patient. Only through good organization can the hospital fulfil its functions in the community. A constitution and by-laws will define the purposes of the institution specify its government and state in general terms the means by which it is to be maintained and operated.

Every hospital must have a governing board which is directly responsible for its operation. Whether the members are designated as trustees, directors, governors, supervisors, commissioners or members of a hospital trust, their duties and responsibilities are the same. Regardless of the size of the hospital, they represent the community in the management of the institution. They are therefore responsible for seeing that the hospital renders the best possible service to the sick at the least cost consistent with efficiency. They determine the policies of the institution with relation to community needs, direct the administrative personnel of the hospital and provide adequate financing. The governors cannot personally perform their many duties but must delegate practically all the actual work to others.

The first concern of the governing board in thus delegating responsibility is to secure adequate medical care for the patients, and this is done by appointment of a medical staff. In the small community it may be impossible to secure physicians who are qualified to treat all types of disease, and herein lies one of the limitations of the small hospital. It should limit its voluntary admissions to patients with types of disease which the members of its medical staff are qualified to treat. In an emergency it may be forced to admit others, but if possible these should be given only temporary care and whenever practical outside assistance should be secured.

It is also necessary to build up an organized personnel who will carry out the orders of the medical staff. This personnel will consist of nurses, dietitians, technicians and various others. It may not be sound policy to employ separate persons to perform each of the functions implied, it is usually necessary to find persons who are qualified to perform several functions.

The small hospital is rarely justified in employing a purchasing agent and storekeeper, yet there must be control of both purchase and issue. Usually the director controls purchasing and places some reliable employee in charge of stores. Accounting demands a trained accountant, but often this person will also act as telephone operator and information clerk and possibly perform other duties. Controlling all this organization is a director, or superintendent, responsible directly and solely to the governing board. This officer is not, as in the larger hospital purely an administrator but will perform many duties which in the larger institution are delegated to subordinates. The governing board is composed largely of persons who are not medically trained and hence are not qualified to interpret properly the professional results. It must rely on medical assistance, and for this purpose it is usual to appoint a joint advisory committee.

The governing board varies from two or three to an indefinite number of members. Most careful consideration should be given to their selection. Only persons who are actually interested and are both able and willing to devote their talents and sufficient time to the work of the hospital in its community endeavors should be given the honor and privilege of membership. The various interests in the community should be represented such as business, women's clubs, church and fraternal organizations and, if the community is an industrial one, organized labor. If the hospital is a recipient of tax funds, there should be a representative of the governmental agency which is directly responsible to the taxpayer. Professional interests should be represented also, but many authorities regard it as inadvisable to have a physician in active practice as a member of this body. In some instances a physician is elected by the local medical society or by the medical staff of the hospital, but even then he sometimes assumes an unwarranted attitude of authority in the management of the hospital. Occasionally there is a tendency on the part of the medical representative to express his personal judgment in matters which come before the board rather than the collective or group opinion of the body he represents. It is believed by some hospital bodies which desire the medical point of view represented on the governing board that it is best to appoint a physician who has retired from active practice but who keeps abreast of the advances of modern medicine.

The method of selection will vary with the ownership, but in every case it should be provided that those appointed to the governing board may perform their duties without undue influence from any outside source. When the hospital is owned and operated by the community through its governmental agency it is undesirable to have that agency directly operate the institution. The man who enters politics incurs obligations which he cannot ignore, and the result in the hospital is too often incompetence or inefficiency. In an institution in which human life and alleviation of suffering are at stake, no degree of incompetence or inefficiency can be tolerated. If the hospital is owned and operated by the community through a joint stock company incorporated not for profit or through any other form of community organization, the members of this organization will elect the governing board of the hospital. The same is true of hospitals owned by church or fraternal organizations.

The organization of the governing board in a small hospital differs in no essential from that found in the large institution. Officers should consist of a president, a vice president, a secretary and a treasurer. These are elected by the governing body and perform the duties which are accepted as pertaining to the several offices. All committees report directly to the governing board.

The qualifications of the director of the hospital as stated by the American College of Hospital Administrators are applicable in their entirety to the director of the small hospital, but the person who is responsible for the management of the small hospital must be a much more versatile person than the one who is in charge of the larger institution, and the smaller the hospital the greater is the necessity for versatility. He must be able to fill any position and to do any piece of work, from firing the boilers in an emergency to performing the actual administrative duties of his or her own office.

The director, sometimes called the superintendent or administrator, is usually a woman and in all but a small percentage

of cases one who has had a basic training as a nurse. One reason for this is that the small hospital is not able to offer a salary that is attractive to a man, but of even greater importance are the duties involved. Of these, the chief is in the nursing department. The small hospital which does not conduct a school of nursing does not require a superintendent of nurses as a separate person. This is a position which is usually filled by the director in addition to her general administrative duties, and it is a position that cannot be filled satisfactorily by a man. The director has a varied relationship. She is, first, the representative of the governing board. The relationship to the medical staff is difficult to explain. In any institution there can be only one head, yet the nurse is always accustomed to take orders from the physician and to obey them without question. This is as it should be when the orders concern the treatment of patients. There is, however, a relationship in which the physician must submit to orders from the director, even though she is a nurse trained in all the customary relationships of nurse and physician. As an administrator, she should not be handicapped by the traditional relationship to the physician. In administrative matters she must give orders and they must be accepted without question by the physician. This dual relationship is perhaps more noticeable in her dealings with the radiologist and the pathologist than with other members of the medical staff. The administration must require the departments of these men to cooperate in making accounting possible. Equipment and supplies are usually purchased through the hospital, and the salaries of technicians and others are a part of the hospital pay roll. The heads of these departments are, however, physicians, and the director must not interfere with their professional activities. She is responsible for knowing whether the results are satisfactory, and this information is obtained through the medical staff. On the other hand, there are many administrative contacts, and in those the director is in the position of authority.

It is as important in the small hospital as in the large hospital to have a woman's auxiliary, because of the valuable assistance, financial and otherwise, that such an organization will render at all times. The small hospital can readily have an organized medical staff. Experience has proved that organized effort in conducting the medical work is absolutely essential, regardless of how limited a number of physicians may be privileged to practice in the hospital. Where there are only three or four physicians, the medical staff may exist in its simplest form, an undifferentiated group. Provision is made for the periodic election of officers, who function in an executive capacity in all matters pertaining to the medical work of the hospital. It is sometimes possible to establish clinical divisions. This tends to fix responsibility more definitely, stimulates scientific interest and facilitates the administration of the professional services. Usually the clinical departments of medicine, surgery, obstetrics and gynecology, and eye, ear, nose and throat may be organized. The responsibility of the hospital management must be emphasized in selecting the medical staff and a regular procedure followed in extending hospital privileges to any physician. Each physician should submit his qualifications in a written application, and these should be investigated by a credentials committee of the medical staff, which reports to the medical staff as a whole, with recommendations. When passed by the medical staff, the applicant is recommended to the governing board for membership in one of the staff divisions. It is considered advisable to extend hospital privileges for only one year with the understanding that, if the applicant's work and conduct have been satisfactory, further extension of privileges will be granted.

There are many ways of promoting cooperation between the medical staff and the governing board. The most satisfactory plan, which has been accepted by hospitals generally, is the organization of a joint conference or advisory committee, composed of duly selected members of the medical staff and the governing board, which meets regularly to discuss problems of mutual concern. The first step in the organization of a medical staff is to formulate complete by-laws, rules and regulations which set forth the type of organization and the duties, responsibilities and procedures. They should be approved by the medical staff signed by the chairman and secretary, and

submitted to the governing board for adoption. One of the major requirements of the approved hospital is that medical staff conferences be held at least once each month. Attendance at conferences should never be less than 75 per cent of the active medical staff. The attendance record of the individual member gives an excellent index of his interest in fulfilling his professional responsibility. Accurate minutes of all medical staff conferences should be prepared by the secretary of the medical staff. Every hospital, large or small, requires complete and acceptable medical records. In the small institution without interns or residents, the records may have to be written by the physicians themselves with whatever assistance the hospital can provide. A medical records department constitutes a major problem in many small hospitals. Physicians frequently fail to realize their responsibility, and the lack of a medical records consciousness on their part is regrettable. The appointment of a member of the medical staff as registrar of medical records or of an active committee on medical records to review the records daily, conscientiously and diligently, to see that they are kept up to a proper standard, is essential. The records should be filed in a conveniently located record room and should be regarded as the permanent property of the hospital, to be released only on order of the attending physician with the patient's consent or by order of a court.

All hospitals should be responsible for adequate clinical laboratory facilities for their patients. These should include as a minimum a small practical clinical laboratory where the essential examinations immediately necessary in assisting the clinician in making or confirming his diagnosis may be made. Too much stress cannot be placed on the importance of routine examination of all tissues removed at operation. Every piece of tissue should be sent to a qualified pathologist for macroscopic examination and a report. A microscopic examination should be made of all tissues at the discretion of the pathologist for further elucidation of the diagnosis. Investigation has shown that the larger accredited clinical laboratories are usually willing to cooperate with the small hospital in providing this necessary supplementary service at a cost that is not prohibitive, and certainly every patient in a modern hospital is entitled to this important service. In the small hospital some difficulty may be experienced in providing supervision and competent technical personnel for the clinical laboratory. Each hospital offers an individual problem, which in most instances can readily be solved. It is desirable for the hospital to have the part time services of a well trained clinical pathologist.

Every hospital should have at least a portable x-ray unit for an emergency service, particularly for the nonambulatory patient. In all instances the department should have medical supervision, for the responsibility of interpreting x-ray films constitutes medical roentgenology and is the work of a physician.

What must the small hospital do in the way of providing services such as metabolism tests, electrocardiography, oxygen therapy and physical therapy? Generally speaking, unless the hospital has a recognized, competent and complete service in these special features, some arrangement should be made with a nearby hospital which can provide them.

The financing of the small hospital offers perhaps one of its greatest problems. Indeed it is hardly conceivable that a hospital with an average occupancy of from thirty to forty patients could provide sufficient funds from its earnings to carry on an adequate service. Supplementing the ordinary revenues with gifts, donations, subsidies and endowments is always desirable. The director may have to be the business manager also, but he will delegate the details of accounting, bookkeeping and collections to a qualified accountant or bookkeeper. He usually oversees purchasing and supplies.

The hospital, though small, requires the usual utilities, which one speaks of as light, heat and power. An engineer will be necessary. Maintenance is an important function which is usually assigned to the engineer and includes repairs, plumbing, electrical service, cleaning, painting and upkeep of grounds. The hospital may have its own small laundry and render a satisfactory service in the care of the linen. On the other hand, it may find a contract with a commercial laundry more convenient and economical. Finally there are the housekeeping activities, which are common to all hospitals and in the case of

the small hospital cannot always be directed or supervised by a trained housekeeper. Often these duties will be assumed by the director of the hospital or one of the staff of nurses. Sometimes, and indeed more commendably, the housekeeping activities are supervised by the dietitian, who combines the duties of her department with those of the housekeeping department.

It is quite possible for the small hospital everywhere to meet at least minimum requirements in the care of the sick and injured, either within its own organization or through supplementing the medical and other services from larger institutions nearby.

### The Principles of Hospital Planning, with Special Reference to the Small Hospital

DR WILLIAM HENRY WAISB, Chicago. An intelligent approach to a hospital planning program can be made only by a careful survey of the actual needs for hospital accommodations in the particular community. Public interest, convenience and necessity are primary considerations which, while given little or no attention in the past, will have to be carefully weighed in the future to avoid the uneconomic duplication of facilities now existing in some communities. The population trends of the community should be carefully studied to secure some idea of future increases which may make additional accommodations necessary. The value of a hospital, large or small, will depend on the caliber of the professional men who compose its medical staff, which is the backbone of the institution. A survey therefore should appraise the professional credentials and standing of the doctors who are to constitute the staff. Needless to say, if a community does not have a sufficient number of reputable practitioners to staff a hospital properly, and others cannot be readily secured, it would be folly to proceed further with the project.

After the completion of a survey, the report should be submitted to whatever local agencies may be interested such as the hospital council, if there is one, the council of social agencies, the local medical society and the chamber of commerce. If the project receives the stamp of approval of such bodies, the sponsors may proceed with the assurance that it is launched on firm foundations and will command public interest and support. If it does not command such approval, it would be wise to defer action until every reasonable objection can be met.

No individual or group, whatever the motives, is justified in foisting on a community a hospital which is intended to be supported by voluntary contributions without first ascertaining the real need for and desirability of such an institution and securing unmistakable public approval. A hospital that is established without these precautions is not in the public interest and may become more of a liability than an asset.

Urgent reasons impel those who are charged with the responsibility of establishing a hospital to select architects who have had extensive experience in this specialty, who maintain an organization and facilities adequate to carry through such a complex undertaking and who possess the other attributes of personality and character so essential in the delicate and varied relationships involved.

The utilization of the services of a qualified medical consultant commences with the original survey of a hospital project, the report of which should embrace sufficient information for the formulation of a comprehensive planning program. The qualifications of a medical consultant on hospital planning are exacting and his success depends on his ability to coordinate and apply all available information bearing on a particular project, to understand thoroughly all the technical details of professional service and to transmit and interpret these to the architect in a comprehensible manner. The consultant should be skilful in analyzing community needs and in devising socially sound and economically feasible ways to meet them. The consultant is not an architect or an engineer, and a definite understanding of his own limitations in these respects is essential to harmonious relationships.

The preparation of final working drawings for a hospital is a time consuming task which should not be commenced until all major problems of planning and design have been satisfactorily settled and this work can proceed uninterruptedly. The completeness of plans and perfection of design may be of

little avail unless competent building contractors are engaged, since the application of the professional skill of the architect is so dependent on the character and ability of the contractors. It is therefore in the interest of the owners to delegate exclusively to the architects the responsibility of selecting contractors considered worthy and capable of bidding on the work. Competition of course is always desirable, but bidding ought to be limited to those firms whose organizations, credit and qualifications are comparable. After bids have been accepted, contracts awarded and work started, there should be required the most rigid compliance with the plans and specifications, and it is the duty of the owners to support the architect in the endeavor to enforce his rulings in any controversy that may arise.

A hospital may be financed from taxation, from a private bond issue, from small voluntary contributions or from specific bequests. Whenever it is possible to utilize the voluntary contribution method there is a greater likelihood of enlisting the enthusiastic interest and support of the community. In the case of the tax financed hospital, it is strongly urged that efforts be made to have enacted an enabling statute setting up a board of trustees so as to remove the institution as far as possible from the stifling effect of partisan political manipulation. The establishment of a community hospital by the floating of a bond issue by private groups is justified only when no other method is feasible and the project is widely endorsed by all the professional and social agencies in the community. It seems to me that if a community really wants a hospital it will establish one by voluntary contributions or bring it into existence through the electorate, and I believe that there is never justification for any group pretending to be eleemosynary to saddle the burden of capital charges deliberately on the prospective patient without his knowledge and consent.

In considering the costs of hospital construction it should be assumed that the structure will be built of fire resisting materials. There are two common methods of roughly computing these costs prior to ascertaining the more exact estimates readily obtained after plans are completed: (1) the cubage method and (2) that based on the cost per bed. Calculating costs on a cubage basis, it is necessary to determine the number and type of beds to be provided and the number of cubic feet that must be reserved for each bed. That is to say, one must calculate not only the actual cubic space occupied by the bed itself or the private room but also that of the halls, stairways, elevator shafts, service rooms, surgical and obstetric suites, x-ray rooms and laboratories, administrative offices, kitchens, storage rooms and other space not used for beds, which often closely approximates 70 per cent of the modern hospital for the acutely ill. Cubage allowances run from 5,000 to 8,000 cubic feet per bed and, using the median of these, one may assume that it is possible to build a general hospital for acutely ill patients with an allowance of 6,500 cubic feet per bed. In estimating cubage for multistoried buildings it is customary to allow not less than 12 feet between floors, which will allow for ceilings of adequate height on all floors.

Hospital construction costs differ in various communities according to the labor and material markets, and further variations result from the differing abilities of architects in the selection of materials. At present in most parts of the northern section of the country a small general hospital can be constructed for approximately 55 cents a cubic foot, but the factors affecting cost are so constantly changing that too much reliance should not be placed on that figure. A fifty bed hospital therefore, with an allowance of 6,500 cubic feet per bed, at a cost of 55 cents a cubic foot, will cost \$178,750 for construction, or a cost per bed of \$3,575. This would include a low pressure heating plant and a laundry room built into the structure. To these figures must be added the fees of the architect and consultant, which will usually be about 6 per cent of the total cost of the project, and the cost of the furnishings and equipment. To provide a fifty bed hospital with modest furnishings and the minimum of equipment required to conduct a modern hospital, an outlay of not less than \$40,000 will be necessary. Summing up the items mentioned, there is a cost of \$229,475, which increases the cost per bed to \$4,589. This does not include any landscaping, walks or roads that might be required,

although when these are not too elaborate their cost can be met within the amount stipulated. I have not considered a nurses' home, the cost of which would be considerably lower per bed than the hospital.

The foregoing data when intelligently used will furnish sufficient information for an approximate calculation of costs early in a hospital project, but unless all the factors mentioned and others are considered, misleading figures will result. I have merely attempted to indicate methods and principles of computing preliminary estimates, and again I emphasize the point that truly accurate information on the cost of a hospital is that obtained only after a project is completed and all factors affecting costs are presented.

### Housing the Small Medical Center

CARL A. ERIKSON, Architect, Chicago. I shall limit myself to hospitals of thirty beds and less. Intended of course to care for the community sick, they have two collateral purposes. One is that by pooling its resources the community is able to provide itself with needed medical equipment, such as x-ray apparatus, laboratories and surgical facilities, far beyond the resources of any individual doctor. By means of the small hospital the community also centralizes its medical skill, represented by doctors, nurses and technicians. These purposes of the hospitals in smaller communities are a very important reason for their construction.

Records show that the small hospital generally seems to have more beds than it needs. The occupancy for 185 hospitals of less than thirty beds according to the 1938 American Medical Association records was but 54 per cent. These were the only hospitals in each of 185 villages and towns in Illinois and six surrounding states. Small hospitals care for all classes of patients. The relation of total admissions to average occupancy was calculated for the 185 hospitals and found to be 40, and for 109 nonproprietary hospitals the relation was 38, the figures for three of the leading voluntary hospitals in Chicago were 35, 38 and 39. Obstetric patients probably claim more beds than in the average city hospital. The records for the 185 hospitals indicate that such patients comprised 16 per cent of those admitted, whereas they comprised but 8 per cent for the nine largest Chicago hospitals. Surgical patients represented 33 per cent of those admitted in twenty small Saskatchewan hospitals, the 1936 records of all the Carolina hospitals ruled by the Duke Foundation show that 60 per cent of the patients were admitted for operations.

The housing of patients is complicated by the wide fluctuation in occupancy to which small hospitals are subject. To meet the economic and clinical needs, multiplied by 2 because of sexes, extreme flexibility in assignment of rooms is obviously needed. Preferably none of the rooms should contain more than two beds, and every private room should be large enough for two beds, about three fourths of the beds should be in two bed rooms and the remainder in private rooms. Such a hospital should be able to average 70 per cent capacity and operate for a short time at 110 per cent capacity if necessary. Twenty beds in this kind of hospital might average fifteen occupied beds without any more difficulty than a twenty-five bed hospital with a number of four bed or larger wards might have with the same annual average occupancy.

Too often the sponsors of small hospitals take as their model some larger hospital, lop off the unnecessary beds and shrink the rest a process that is unsatisfactory. It is very simple to assign 60 square feet to each bed in a two or four bed ward, it is something else to use it comfortably. The generally accepted minimum of 80 square feet per bed is none too large for practical operation, nor does it often permit anything more than the minimum distance between patients. The single room should preferably contain not less than 160 square feet, which will permit its use for two beds when needed. At least two rooms and preferably four in every hospital should have individual toilets, which will permit their use in isolation cases and at other times as private rooms. Convenience and accepted technique dictate that each room should have a wash basin if the building budget can be stretched that far. A closet or wardrobe should not be overlooked. A utility room and linen closet, a janitor's closet, toilets and a bath, simply equipped and detailed, are a necessary accompaniment of each group of patients' rooms.

The patients should be grouped together to form a single nursing unit, to divide them among two or more floors either increases nursing costs or decreases the nursing care. Each added floor of patients requires another set of baths, utility rooms and linen closets, at a corresponding cost.

A small reception room adjoining the entrance is a necessity, and it should be completely shut off from the hospital corridor. Administration must be of the simplest character, but a small office is a necessity and should adjoin the entrance and reception room. In view, however, of the limited nursing and administrative personnel and their varied duties, the nurse's charting desk should be so placed that it controls, when needed, the main entrance as well as all the patients' rooms.

The twenty-five bed hospital will average about one operation every day and one birth every four or five days, the ten bed hospital, one operation every third day and a birth every ten or twelve days. In the hospital as small as ten beds one operating room should be sufficient, supplemented when necessary by a medical service room. The twenty-five to thirty bed hospital should have an additional operating room. The operating rooms should be about 16 by 20 feet. Scrubbing can be done in the operating room and many surgeons would prefer this. A surgeon's dressing room and toilet are essential. The nurses' workroom should be large enough to make a really comfortable workroom, probably not less than 60 to 80 square feet of clear floor space, with cases, closets, sinks, work tables and sterilizers outside this area.

Opinions will vary as to the desirable equipment. Certainly there will be an x-ray machine and a laboratory, beyond that I hesitate to make any predictions. Most of the equipment, however aside from some forms of x-ray apparatus, is small and easily handled. The cardiograph, most forms of electrotherapy machines, the essential of basal metabolism apparatus, as well as many of the smaller x-ray machines, are readily portable. One room can be used for all of this equipment. To avoid cluttering up the room it should be possible to store the unused equipment in adjacent closets.

Without a balanced budget the small hospital cannot long exist, hence it must have a rigorously limited personnel. The duties of laboratory, x-ray and physical therapy technicians will have to be divided among the doctors or the nursing personnel or allotted to a single technician. A combination of a laboratory and the drug room in one seems feasible. I would suggest a third use for this room, that of x-ray dark room. All the diagnostic and therapeutic services should if possible be grouped together, as it makes for the best use of limited personnel. However, x-ray and physical therapy facilities should be readily accessible to outpatients. If they are all placed on the same floor with the patients, and that floor is close to the ground, there is no need for an elevator or large stairs and substantial economies in building and operation result.

A laundry may not prove to be an economy. The boiler room should be as simple and as largely automatic as possible. Cheap electric power and bottled gas have largely eliminated one of the former problems of the small hospital, how to get high pressure steam for sterilizing. Examination of the plans of many small hospitals discloses that most of the builders were not "store room conscious" at the time of planning, the management subsequently has no doubt become painfully so.

Two of the three functions of the hospital have been discussed, the third is the centralization of the medical personnel. The housing of nursing and technical personnel is essential, their skill must be on tap twenty-four hours a day to care for emergencies. They must therefore have quarters in or adjoining the hospital. Small hospitals do not have interns and few can afford to pay a resident physician, yet a doctor must always be on call. Probably in these days of the telephone and the automobile any doctor in a small community can get from his home to the hospital quicker than the resident in the large hospital gets to his patient from his quarters.

As a layman I would expect benefits from the association of public health activities with the curative medical practice of the small hospital. Some free outpatient work must be done at the hospital. It seems reasonable to assume that tuberculosis, venereal disease, pediatric, maternal, orthopedic and other governmentally supported clinics should be held at the community medical center. Also, if there is a public health officer, should

he not be close to these facilities and to the headquarters of the practicing physicians rather than at the county court house?

It is generally agreed that hospitals large or small should be of fireproof construction, but if the hospital has only one story, masonry outside and in the corridor walls, with a fire resistive first floor and wood ceiling joists and rafters plastered on wire lath may make an acceptable substitute.

The principles of construction are identical with those of the larger hospital but their application to the small one requires a bit of common sense, a flashlight is a part of the equipment of a night nurse may be just as efficient as a built-in night light, an infinitesimal portion of the cost. The finish should, so far as is practicable, be kept within the scope of the local craftsmen. Terrazzo and tile may prove expensive if the contractor and crew must come from distant points for a small job. Local resources in building material should be carefully canvassed and used to the utmost.

#### DISCUSSION ON THE SMALL HOSPITAL

EDGAR MARTIN, Architect, Chicago. Each community has its own hospital problem, different from and entirely independent of that of other communities. A hospital illustrative of the paper presented by Dr. Walsh contains 300,000 cubic feet. There are two five bed wards and thirteen private rooms, all of which are convertible into two bed wards and four special beds. This normally provides thirty beds. Depending on the intensity of use of the two bed wards, the capacity will be either twenty seven or forty beds and in an emergency the number of beds in the wards can be increased, the solarium can be used as a ward and the hospital can be expanded to a bed capacity of forty eight beds.

Every hospital room articulates with a subtility room. This arrangement does away with the commode and bedpan travel down the corridors. It is a little more expensive, but when the special facilities are provided the extra expense will be amortized in a short time by the saving in nursing charges. In a number of the private rooms the subtility room opens from a connecting corridor. A wide building is always less expensive than a long building, and there is an arrangement whereby a single door swings on a quadrant between two door openings, so arranged that on a patient's entering the bath the door closes off from the adjacent room and automatically locks. The patient on leaving automatically unlocks the door in the other room, and the toilet then is in a position for use by the other patient. While one patient is using the toilet, there are two doors closed between it and the adjacent room shutting out all sounds.

The need has been emphasized both by Dr. MacEachern and Dr. Walsh of the necessity of the departmentalization of the various medical services. Departmentalization is complicated in any hospital, but it is particularly complicated in the small hospital. The casualty department is the one department in no ratio to the bed capacity of the hospital. It is placed in a part of the building where the commotion and excitement that always attend accident cases will least disturb the routine services of the rest of the hospital. It has a secluded entrance, with adequate space for relatives and friends and for less injured patients who are waiting while the more seriously injured are being taken care of. A two table minor operating room is provided which articulates closely with the x-ray department, the splint storage room and the operating suite, and in the operating suite is a reserve orthopedic table for use in the case of fractures.

The obstetrics department is placed where the noise is less disturbing to the rest of the hospital and where absolute privacy is obtained. The waiting patients and the postdelivery patients are separated from the delivery suite. The nursery is so placed that the general public and relatives can view the babies without intruding on the privacy of the maternity patients. The nursery is equipped for infectious disease technic and has plate glass windows opening on the visitors space.

The administrative section is self contained, entirely outside the zone of medical and nursing care. The kitchen department is provided with full facilities for dietetics as well as general foods and food storage.

(To be continued)

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL March 18 page 1099

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS. Parts I and II. Medical centers having five or more candidates desiring to take the examination, May 12 (Part II only—limited to a few centers) June 19 21 and Sept 11 13. Ex. Sec. Mr. Everett S. Elwood 225 S. 15th Street Philadelphia

#### SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY. An Affiliate of the American Board of Surgery. Oral examinations for all candidates. St. Louis, May 13 14. Written. Various places throughout the United States. Sept. 9. Applications must be filed by July 11. Oral. Part II. Philadelphia Oct. 14 15. Sec. Dr. Paul M. Wood 745 Fifth Ave. New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY. Philadelphia Oct. 30 Nov. 1. Sec. Dr. C. Guy Lane 416 Marlboro St. Boston.

AMERICAN BOARD OF INTERNAL MEDICINE. Written. Various sections of the United States. Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec. Dr. William S. Middleton 1301 University Ave. Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY. General oral clinical and pathological examinations for all candidates. Part II examinations (Groups A and B) will be held in St. Louis May 15 16. Sec. Dr. Paul Titus 1015 Highland Bldg. Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY. Written. Various cities throughout the country. Aug. 5. Oral. St. Louis May 15 and Chicago Oct. 7. Sec. Dr. John Green 6830 Waterman Ave. St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY. St. Louis May. Applications must be filed with the Secretary on or before April 1. Sec. Dr. Fremont A. Chandler 6 N. Michigan Ave. Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY. St. Louis May 12 13 and Chicago Oct. 6 7. Sec. Dr. W. P. Wherry 1500 Medical Arts Bldg. Omaha.

AMERICAN BOARD OF PATHOLOGY. Richmond Va. April 3 4. Sec. Dr. F. W. Hartman Henry Ford Hospital Detroit.

AMERICAN BOARD OF PEDIATRICS. Cincinnati Nov. 15. Appointments must be made before July 15. Sec. Dr. C. A. Aldrich 723 Elm St. Winnetka Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY. Chicago May 13. Sec. Dr. Walter Freeman 1028 Connecticut Ave. N.W. Washington D. C.

AMERICAN BOARD OF RADIOLOGY. St. Louis May 11 14. Sec. Dr. Byrl R. Kirklin 102 110 Second Ave. S.W. Rochester Minn.

AMERICAN BOARD OF SURGERY. Part I. Simultaneously in various centers throughout the United States. April 3. Part II. New York May 8 and May 9. Sec. Dr. J. Stewart Rodman 225 S. 15th St. Philadelphia.

AMERICAN BOARD OF UROLOGY. White Sulphur Springs W. Va. May 26 28. Sec. Dr. Gilbert J. Thomas 1009 Nicollet Ave. Minneapolis.

### Michigan October Examination

Dr. J. Earl McIntyre, secretary, Michigan State Board of Registration in Medicine, reports the written examination held at Lansing, Oct. 12-14, 1938. The examination covered fourteen subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-one candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine	(1938)		85.9*
Loyola University School of Medicine	(1938)		78.7†
Northwestern University Medical School	(1937)		83*
Rush Medical College	(1937) 82.4 *	86.7 *	81.8*
School of Medicine of the Division of Biological Sciences	(1938)		87.1*
University of Louisville School of Medicine	(1937)		85.5
University of Michigan Medical School	(1936) 87.4	(1938)	81.7*
University of Minnesota Medical School	(1933)		78.9
Creighton University School of Medicine	(1937)		80.4
Cornell University Medical College	(1937)		82.2
New York Medical College and Flower Hospital	(1938)		81.2*
Duke University School of Medicine	(1937)		83
University of Cincinnati College of Medicine	(1937)		86.9*
Marquette University School of Medicine	(1938) 83.6 *	84.5†	
University of Wisconsin Medical School	(1937)		89.1
University of Western Ontario Medical School	(1936)		85.3*
McGill University Faculty of Medicine	(1937)		83.6*

\* License has not been issued.

† This applicant has completed the medical course and will receive the M.D. degree on completion of internship. License has not been issued.

### Maryland (Homeopathic) December Examination

Dr. John A. Evans, secretary, Board of (Homeopathic) Medical Examiners, reports the written examination held at Baltimore, Dec. 13-14, 1938. The examination covered nine subjects and included seventy questions. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. The following school was represented:

School	PASSED	Year Grad	Per Cent
Hahnemann Medical College and Hospital of Philadelphia	(1937) 80	(1938) 86	90 94

## Book Notices

**Personality Structure in Schizophrenia. A Rorschach Investigation in 81 Patients and 64 Controls.** By Samuel J. Beck, Ph.D., Head of the Psychology Laboratory, Department of Psychiatry, Michael Reese Hospital, Chicago. With a preface by C. Macle Campbell, M.D., Nervous and Mental Disease Monograph No. 63. Boards. Price \$2. Pp. 98, with 12 illustrations. New York: Nervous and Mental Disease Publishing Co., 1938.

This excellent monograph reports a study of the fantasies produced by persons when exposed to the observation of outlines created by the "ink blot method" and a critical analysis of the verbalizations regarding what they fantasied as a reaction to this observation. The test was originally devised by Rorschach for the study of schizophrenia, and Beck, following Rorschach, uses the method to distinguish between the schizophrenic and other personality problems. This test, which is being utilized more and more for diagnostic and prognostic purposes, offers an objective approach to the whole problem of mental illness. The original work by Rorschach, who died in 1922, has been carried on by Oberholzer and his students and has been further influenced by Behn-Echenburg (who worked with adolescents), Schneider (with inhibited children), Pfister (with the feebleminded), M. Bleuler (with adult siblings), von Verschuer (with twins), Veit (with Parkinson's disease) and Munz (with personality types according to Kretschmer and others). In this country D. M. Levy, who worked with Oberholzer, brought the test to the Institute for Child Guidance in New York, where Beck began its application and soon developed into one of its foremost exponents and technicians. As Beck states, "What appears from the Rorschach experiment is that, in each kind of personality, whether it be healthy adult, problem child, depressed, hysteric, schizophrenic or any other, certain psychological processes hang together and the organization of these processes is the particular kind of personality. . . it is the structure so found in schizophrenia . . . and comparing it with that in individuals not so suffering that the present study attempted to inspect." Every psychiatrist and psychologist should familiarize himself with this test because it is certain to occupy a foremost position in any study of personality structure.

**La tuberculose pulmonaire chez les sujets apparemment sains et la vaccination anti-tuberculeuse.** Par L. Sayé, professeur de physiologie à l'Université de Barcelone. Paper. Price 60 francs. Pp. 256, with 88 illustrations. Paris: Masson & Cie, 1938.

This monograph contains some of the most modern and most needed teaching in tuberculosis literature. It may be compared to the back of a tapestry that is rarely ever seen. Sayé has turned the tuberculosis tapestry around so that the unseen side comes into better view. An extensive review of the literature interspersed with his own results makes up this report.

Tuberculosis in those apparently well is the seed from which an important part of clinical disease emanates and constitutes the unseen source of the disease that is the greatest barrier in the way of control and eradication. While all tuberculosis arises from an exposure to some open case, those who are exposed to known open cases present from five to six times as much clinical disease as is found in the general population. In one of the author's series 18 per cent of such cases were open. This introduction may be considered the principal theme of the work. It is a question first of contact, second of dosage, and then to a minor degree environment, age, race, sex and occupation. Owing to the fact that many persons with open tuberculosis are apparently well, they are one of the greatest problems of tuberculosis workers today.

Surveys of various authors within general populations reveal figures for tuberculosis in the apparently healthy that vary widely but are roughly proportional to the death rate of the particular group. It is roughly 1 per cent for countries like the United States and Germany and rises to about 2 per cent in most other European countries with a few exceptions, such as Poland, where it is over 3 per cent. In China it is between 7 and 8 per cent. These figures have been obtained by tuberculin and x-ray surveys on soldiers, students and various occu-

pational and social groups. Important are the figures for medical students and nurses. Nurses on the average have five to six times the general rate, but some tuberculosis services, especially some handled by Sisters of Charity, have rates as high as 12 per cent. In other places where antiseptic technique has been used it drops almost as low as the rate for the general population. The rate for medical students increases about four times that for other professional students, from the first to the fourth year inclusive.

The occupation is not as important as the contacts within the occupation and the public health intelligence of the groups. Prisoners have a high rate (9 per cent for the sixth decade) and Chinese students, Indians and Negroes have a high rate (from three to four times the average) while certain universities (Yale, Pennsylvania) have a low incidence of open disease (about half the general incidence) in spite of a relatively high infection rate. [This is presumably due to an elimination of heavy dosage by a knowledge of sanitary precautions.—Ed.]

The ages most affected include principally infants and young adults over other ages, while young females predominate over males. Many of the symptomless forms have been followed by x-ray and bacteriologic studies. With cultures and animal inoculations on sputum and particularly stomach washing, it has been found that persons who do not show symptoms may discharge bacilli for three or four years after healing has begun. The lymph nodes in skin and mucous types clear up within a year or two.

The diagnosis is best made with the x-rays and tuberculin, supplemented by cultures and animal inoculations on sputum and stomach washings. The author uses a combination of the Pirquet and Mantoux tests, stepping the latter up as high as 1 mg if necessary. Then for a diagnosis of latent or active disease the fluoroscope, paper films and finally, in doubtful cases, regulation films are used in order. By this progression the cost is kept at a minimum. There is a negative agreement of 47.3 per cent and positive agreement of 10.5 per cent (total 58.8 per cent) of films and fluoroscopic study. The films are superior by around 30 per cent with certain cases of each in doubt.

There is a small but important group in which there are no physical or x-ray signs but which are positive for tubercle bacilli. This may be due to small foci invisible on the roentgenogram, to bacilli present in apparently normal tissue, to lesions not yet developed, to lesions behind the heart, to ruptured lymph nodes, to cleared pneumonic or epituberculous lesions or to tuberculous bronchitis. A very few of such bacillary observations are nontuberculous or are extraneous bacilli. On rare occasions there may be positive clinical signs with all else negative.

Reviewing work of various authors, Sayé shows how prognosis is worse in primary lesions with large calcifications and is roughly dependent on the size of the dose and the age of the infected patient. In ulcerative lesions 79 per cent of patients are dead after fourteen years. [This perhaps does not include recent figures.—Ed.] There are 8 per cent of late exacerbations in primary lesions up to 25 years, 10 per cent of small exudative foci are open after three years. Prognosis is favorable in 63 per cent of early and moderately advanced cases, 34 per cent in moderately advanced and far advanced cases and 2 per cent in far advanced cases. [This again probably does not include the changes brought about by the intensive use of modern surgery.—Ed.]

The author's recommendations for treatment are generally sound, including a conservative extension of pneumothorax to include all types of open cases and the use of gold salts in the treatment of certain lymph node types of children. The author has been one of those to use gold salts with apparent success. Indications for pneumothorax in closed cases, in the author's opinion, is not well defined.

In the chapter on prophylaxis the author makes out an excellent case for BCG, citing figures that show an increase in protection of treated cases from four to ten times over untreated cases.

The book is recommended for physicians and tuberculosis workers.

**Thoracic Surgery** By Ferdinand Sauerbruch Professor of Surgery in the University of Berlin and Laurence O'Shaughnessy F.R.C.S., Hunterian Professor in the Royal College of Surgeons of England. A revised and abridged edition of Sauerbruch's *Die Chirurgie der Brustorgane*. Cloth. Price \$13.50. 1 p. 791 with 230 illustrations. Baltimore: William Wood & Company, 1937.

This moderate size volume is an entirely new work. It is a revised and abridged edition of Sauerbruch's three volume work "Die Chirurgie der Brustorgane" based on this author's knowledge and experience of surgery of the chest gathered during his work at the clinics of Zurich, Munich and Berlin. It first appeared in 1918 as a small single volume, in 1921 in two volumes, and in 1928 and 1930 in three volumes. Sauerbruch is unquestionably the foremost authority on chest surgery in Germany. Mr. O'Shaughnessy, a British surgeon specializing in thoracic surgery, worked for a considerable time in Professor Sauerbruch's clinic and the new volume was written by the two surgeons in collaboration. It contains the best in German surgical practice and, in addition the most recent advances and most valuable operative procedures developed in Great Britain and the United States. The volume is strictly down to date and presents in concise form the entire subject of thoracic surgery including the significant contributions of the last ten years.

A few chapters are somewhat disappointing. The section on surgical relief of cardiac ischemia reviews all the older work and includes the more recent operations, even O'Shaughnessy's operation (1936) in which a pedicled omental graft is sutured to the heart, and Lenzius's operation (1937) in which, after partial excision of the pericardium, the lung is attached to the heart. But these operations are not described in enough detail and are not illustrated. The same criticism applies to the surgical treatment of angina pectoris. Here no mention is made of total thyroidectomy, none of the operations are illustrated, no statistical information is given, and the authors conclude by stating that until the surgical treatment of angina pectoris can rest on a more secure anatomic and physiologic basis the successes obtained in a few isolated cases should not encourage its general adoption. White's experiences alone with paravertebral injection with alcohol of the stellate and upper five dorsal ganglions would seem to warrant more optimism.

Although it is impossible to compress into one volume all the valuable information contained in Sauerbruch's three volume system, this volume does contain most of the essentials and, in addition, much that has been learned since his last edition appeared in 1930. For this reason those surgeons who already possess this set will welcome having the work brought down to date, and for those unable to read German this volume will be unusually valuable.

**Spectrochemical Analysis in 1938. A Companion Book to 'Spectrochemical Abstracts 1933-38.'** By F. Twyman F.R.S. Cloth. Price 4s. 4d. Pp. 68 with 16 illustrations. London: Adam Hilger Limited, 1938.

Twyman, physicist to Adam Hilger Limited, manufacturer of optical instruments, has now presented to his fellow workers a "last minute" account of references pertaining to spectrochemical analysis. The monograph is divided into six sections and a subject index. Twyman makes a candid selection of the literature. The second chapter, on quantitative spectrochemical analysis with the microphotometer, is of importance because it is the field which receives most attention at present. Chemists, physicists and biologists interested in this branch of science need this booklet on their study table.

**Chemie und Technik der Gegenwart** Herausgegeben von Dr. H. Carl, Dozent an der Universität Leipzig. Band XIV. Vitamine und Hormone und ihre technische Darstellung. Teil 3. Darstellung von Hormonpräparaten (ausser Sexualhormonpräparaten). Von Dr. Erich Vincke. Boards. Price 7.50 marks. Pp. 162 with one illustration. Leipzig: S. Hirzel, 1938.

The third volume of the series on vitamins and hormones is about the technical preparation of the hormones other than sex hormones. A portion of the book is concerned with a discussion of general methods of preparation, with suitable references. There is a brief general description of methods of preserving materials and extracting the active principles with various solvents. Then follow chapters devoted to individual products,

with a brief discussion of the chemistry, methods of detection and estimation and detailed description of methods of preparation. There is also a brief discussion of the clinical use of some of the products. At the end of each chapter there is a list of articles in the scientific literature followed by a separate tabulation of important patents in various countries. There are a number of useful tables throughout the book which provide a list of commercial preparations of each hormone that are available.

**Kliniske Studier over dissemineret Sklerose og beslægtede Lidelser Af Mogens Ellermann** [Clinical Studies on Disseminated Sclerosis and Related Diseases]. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad. København: Paper. Pp. 233. Copenhagen: A/S Oscar Fraenckel & Co., 1937.

This excellent monograph is based on 122 cases of multiple sclerosis and thirty-four cases of related diseases (lethargic encephalitis and disseminated encephalomyelitis), with brief records of all cases which were studied in Copenhagen clinics. There are separate chapters for each of the principal symptoms and syndromes encountered, such as sensory disturbances, ataxia, ocular symptoms, sphincter disturbances and psychic symptoms. In each such chapter a review of the literature is first given, followed by an account of the author's experience. There are lucid chapters dealing with the relationship and contrasts between disseminated sclerosis, lethargic encephalitis, encephalomyelitis and neuromyelitis optica. Every neurologist who can read Danish will be grateful to the author for this splendid compilation.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Malpractice Expert Witness Must Have Knowledge of Standards of Local Physicians**—The plaintiffs, husband and wife, sued the defendant for malpractice, alleging that he improperly, negligently and carelessly prescribed for the wife a remedy referred to as "phanodorn." The trial court entered a judgment of non-suit at the conclusion of the plaintiffs' evidence, and the plaintiffs appealed to the district court of appeal, second district, division 2, California.

It was incumbent on the physician, said the court, to apply that degree of care, skill, knowledge and attention ordinarily possessed and exercised by physicians under similar circumstances in the locality in which the treatment was administered. To justify submitting the issues to the jury, it was necessary for the plaintiffs to prove negligence or lack of care or skill on the physician's part by expert witnesses familiar with the practice concerning the patient's infirmities in the locality in which she was treated. Without such testimony no valid judgment could be rendered against the physician. To establish the negligence of the defendant, the plaintiffs presented as witness a physician who testified that he was a graduate of a medical college and that he had practiced in Los Angeles, the locality in which the treatment was rendered, since 1933. A hypothetical question was then propounded to him to which objection was made and sustained. The plaintiffs then rested their case without making any further effort to show the competency of the witness.

The district court of appeal held that the trial court did not err in sustaining the objection to the question propounded to the witness because it was not shown that the witness was familiar with the work and practices of other physicians in the community in which the treatment was given. In so holding the court relied on *McGuire v. Baird*, 9 Cal. (2d) 353, P. (2d) 915, in which the Supreme Court of California said:

The qualifications of a witness to testify in a malpractice case are definitely and clearly established by the decisions of the courts of this state. In the recent case of *Rasmussen v. Shickle*, 9 Cal. App. 2d 426, 430, 41 P. 2d 184, the court very aptly defined such qualifications in the following language: To qualify as such expert in a malpractice case against a

physician the witness must not only show himself to possess learning and knowledge of the subject of inquiry sufficient to qualify him to speak with authority on the subject but also a familiarity with the treatment and degree of care and skill of other practitioners in the locality in question sufficient to qualify him to say whether or not the defendant's treatment was consistent with what other physicians in the exercise of reasonable care might do under similar circumstances.

Since the plaintiff's case was not supported by the testimony of expert witnesses, the trial court, in the opinion of the district court of appeal, properly granted a motion for a non-suit—*Taylor v Fishbaugh (Calif)*, 79 P (2d) 174

**Workmen's Compensation Acts Strangulation of Pre-Existing Hernia Not Compensable**—The claimant's husband had suffered from hernia since childhood. While the hernia had troubled him frequently, he had worked as a miner for at least thirty years. On March 12, 1937, in the course of his employment in a mine, he assisted in moving a piece of slate weighing about 700 pounds. About thirty minutes later he complained of being sick and went home. His condition continued to grow worse and a physician was called, who caused the employee to be taken to a hospital where he was operated on for a strangulated hernia. A secondary operation was performed some days later, pneumonia developed and the employee died March 18. His widow, the claimant in the present case, filed a claim for compensation which was denied by the compensation commissioner. This denial was affirmed by the compensation appeal board and the claimant appealed to the Supreme Court of Appeals of West Virginia.

The workmen's compensation act of West Virginia provides that an employee may be compensated for hernia if (1) there was an injury resulting in hernia, (2) the hernia appeared suddenly, (3) it was accompanied by pain, (4) the hernia immediately followed an injury, (5) the hernia did not exist prior to the injury for which compensation is claimed. The act, in the opinion of the court, intended to bar compensation for hernia in cases in which the disability existed prior to an injury for which compensation is sought. It refers to "all claims for compensation for hernia," and to obtain compensation therefor certain things must definitely be proved to the satisfaction of the commissioner, the first being "that there was an injury resulting in hernia." It cannot be said, the court concluded, that a hernia resulted from an injury in a case, such as the one at bar, in which the hernia had existed from childhood.

For the reasons stated, the denial of compensation was affirmed—*Jordan v State Compensation Commissioner (IV Va)*, 197 S E 20

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

### American Journal of Ophthalmology, St. Louis

21 1315-1426 (Dec.) 1938

- Eye Lesions in Experimental Infections with Special Reference to Arthritis C. Berens, D. M. Angevine, I. Cuy and S. Rothbard New York—p. 1315

- Treatment of Delayed Union and Nonunion of Fractures by Subcutaneous Drilling R. A. Griswold Louisville, Ky.—p. 135

**Localization of Intracranial Lesions.**—Lewy determined the relationship of areas of hyperpathia of the scalp to the localization of intracranial tumors, abscesses, subdural hematomas, arachnoiditis and meningeal scar formations. He gives a survey of the type of lesions found in 100 patients and the location of the seventy-nine tumors. The result of these examinations showed a correlation between the location of the area of cutaneous hyperpathia and the accompanying intracranial lesion. The exact shape of the cutaneous areas varies in different cases, and the relationship of the zones of the scalp to the underlying intracranial process is an approximate one. Although the area of hyperpathia does not represent the exact location of the tumor it gives a sufficient indication of the area at which the bone flap should be turned down. Statistics show that the majority of cerebral tumors exhibiting areas of hyperpathia of the scalp were tumors above, at or just below the surface of the brain, often involving the meninges directly or indirectly. One tumor although deep seated, was accompanied by an area of hyperpathia. A possible explanation for this exception is that the middle cerebral artery was embedded in the tumor. In tumors of the cerebellum and of the sphenoidal ridge the local-

ization could be outlined more accurately. The majority of the tumors of the posterior fossa affect in some way the cervical roots and cause a hyperpathia. However, deep seated cerebellar tumors, producing traction on the tentorium, show, in addition or exclusively, a circular hyperpathia over the forehead or above the eyes. In tumors of the sphenoidal ridge, a careful sensory examination, including electrical methods, may help in determining whether the first division of the fifth nerve is involved or whether the lesion encroaches on the second and third divisions in the neighborhood of the foramen rotundum and foramen ovale. Such a differentiation may change the surgical approach. Brief histories of six cases illustrate the specific field of application of this method.

**Splenectomy in Blood Disorders.**—Andrus and Holman state that the value of splenectomy in congenital hemolytic jaundice, thrombopenic purpura and Banti's disease is well recognized, although the part played by the spleen in the production of these diseases is not clear. This will continue to be true until these diseases can be reproduced in animals. The results of splenectomy in these three diseases amply justify its use, but attempts to expand its indication beyond these have been attended almost uniformly by a considerably higher mortality and by disappointing results so far as cures are concerned. The authors report a series of fifty cases in which splenectomy was done. By removing the spleen in hemolytic jaundice only a portion of the cells responsible, but fortunately a sufficient portion to restore a more nearly normal balance between blood formation and blood destruction in most cases, is removed. There were no operative deaths in seventeen cases, but two patients have died since operation. Patients with definite thrombocytopenic purpura in the acute form are not good operative risks and this fact will deter surgeons from operating on them except as a last resort. Various medical measures, particularly repeated blood transfusions, may arrest the hemorrhage or even bring about an enduring remission of the disease in some cases and the injection of ascorbic acid is sometimes capable of producing remarkable improvement or remission. However, in many cases even these measures fail and but rarely produce the really spectacular results often seen following splenectomy. There were no deaths from the operation on twelve patients, although one patient died five months after operation with persistent thrombopenia and anemia. It is possible that the diagnosis was wrong and that she should have been classified as having aplastic anemia. All the remainder are well and have practically normal erythrocyte counts from six months to four and one-half years after operation. Splenectomy was performed in two cases of atypical hemorrhagic purpura, atypical in that thrombopenia was absent. In one, a boy of 14, who had had symptoms of hemorrhage, purpura and the development of ecchymosis from slight trauma for eight months, an excellent result was obtained. The other patient was a woman of 39 who had had similar symptoms for many years. During the year which has elapsed since her operation she has shown no improvement. The removal of the spleen in Banti's disease seems definitely warranted in the early stages and may alleviate some of the symptoms over a considerable period. The benefit which results would seem to be due to the reduction of the amount of blood coming to the liver through the portal vein which follows splenectomy. The operation is attended with certain risks. In many of the cases the platelets reach high levels after operation and thromboses are common. There were no operative deaths in eight cases, but one patient died two years after operation of progressing cirrhosis with ascites. The longest time which has elapsed since operation is three and one-half years. Two patients have suffered recurrence of hemorrhage. In four cases of erythroblastic (Cooley's) anemia there were no operative deaths, but two of the children have since died, one eight months and one two years after operation, of progressive anemia and pneumonia. The other two children are living three and one-half and four years after operation, but both have erythrocyte counts of slightly over 3,000,000 cells, and hemoglobin values around 50 per cent. The authors have performed splenectomy in three cases of true aplastic anemia, in one frankly as an experiment in a patient who was rapidly becoming worse. The course of the disease was not altered by the procedure. She died nine days after operation from continued bleeding from the gums and vagina and with progressing anemia. While the two other patients

appeared to derive temporary benefit, both suffered a relapse and died, one seven weeks and one ten months after operation. Splenectomy was also performed on a child with nonhypoid histiocytosis. The operation apparently alleviated somewhat the discomfort caused by the spleen and temporarily relieved the purpuric manifestations but did not arrest the progress of the disease. Splenectomy was also undertaken in a case of leukemia. The man survived the operation but was not improved, and at postmortem, four months later, leukemia was established. In one case characterized by weakness, anorexia and vague pains of the upper part of the abdomen the preoperative diagnosis was Banti's disease. Splenectomy was performed and the patient reacted poorly after operation and died eight hours later with hyperpyrexia. Postmortem examination revealed sarcoma which had involved the spleen, liver, pancreas, kidney and mesenteric nodes. Another operative fatality occurred in an Italian boy, aged 12, who had suffered from weakness, vague indigestion and frequent epistaxis for about six months. Following paracentesis the child became jaundiced, the anemia became more marked and the fluid reaccumulated rapidly. Splenectomy was undertaken as a last resort. The jaundice increased rapidly after operation and the patient died with cholemia three days later. The post-operative diagnosis was nodular cirrhosis.

**Efficacy of "Coley's Toxin" in Sarcoma**—The effects of intraperitoneal injections of "Coley's toxins," of killed seven-day dextrose broth cultures of *Streptococcus erysipellatis*, *Bacillus prodigiosus* and *Bacillus coli*, were studied by Brunschwig on sarcomas of the subcutaneous tissues of rats, induced from the animals' own tissues by carcinogenic hydrocarbons. Transplanted neoplasms were not employed. No evidence of inhibition of the growth of the tumors was obtained. In a significant number of instances the tumors of injected animals exhibited a marked hyperemic and hemorrhagic reaction. It is assumed that this was a reaction to the injection of bacterial products, since such changes were not observed in control animals and were definitely of a different type, macroscopically, from the spontaneous degenerative changes sometimes observed in such neoplasms. These reactions, as indicated, did not appear to restrain the growth of the neoplasm.

## Industrial Dermatitis Due to Photosensitization

Foerster and Schwartz observed that dermatitis and melanosis are common in industries in which tar and pitch are handled and that the preparations are important occupational hazards. These facts are not generally known in this country. More than 500 men were examined in four factories making electric conduits, more than half of whom had either melanosis or cutaneous lesions, chiefly dermatitis. The condition was confined to handlers of pitch or of pitch products, but those most intimately in contact with pitch were affected the least, while those who had the most severe dermatitis and the most intense pigmentation were outdoor workers. The pigmentation was diffuse and intense, considerably darker than ordinary sun tan, and it was confined to the surfaces exposed to sunlight. Pitch comedos and folliculitis on the face, neck, hands and forearms were commonly observed, and keratoses and papillomas were found occasionally. While some men were affected more

severely than others, apparently none sufficiently exposed were immune. Tolerance with persistent pigmentation developed in some men, but most of them had to be rotated between various jobs and some were so hypersensitive that they could not be employed in the daytime but worked satisfactorily on night shifts. The pigmentation was not permanent but it persisted at least for several months after the workmen were no longer exposed. On the basis of their investigation the authors conclude that pitch dermatitis and melanosis are the products of true photosensitization resulting from exposure to specific spectral bands of light. These conditions do not appear to result from chemical contact sensitization of the type of dermatitis venenata or from allergic predisposition and commonly occur in previously normal skin of normal subjects. The photosensitization occurs through local exogenous activity of a specific photosensitizer. The authors believe that these photosensitizing radiations predominate in the short wavelengths of the sun's spectrum, chiefly between 3,900 and 5,000 angstroms. Reactions may be obtained in the midultraviolet portion of the spectrum, apparently only after prolonged exposure to rays of wavelengths longer than 2,500 angstroms. Their investigations failed to establish definitely one specific ingredient of pitch or coal tar as the photosensitizing agent in pitch melanosis and dermatitis. However, they believe that the dermatitis and melanosis probably result from photosensitization by different ingredients of coal tar, possessing different fluorescent spectrums from those involved in the production of epithelioma and epitheliomatous conditions.

**Sweat as a Fungicide**—Peck and his collaborators studied the fungicidal power of human sweat and of its individual components. When this fungicidal power was established, an attempt was made to treat fungous infections by topical application of some of the ingredients, singly and in combination. The importance of such therapy does not lie in the fact that new and startling fungicidal agents are presented but in the fact that a more nearly physiologic approach to the therapy of fungous infections is proposed. According to their experiments, alkalinized thermal sweat had no fungistatic property until concentrated. Dilute heat sweat obtained from a Negro boy and not alkalinized was fungicidal at a  $pH$  below 7. Analysis of samples of sweat revealed the presence of propionic, acetic, caprylic (caproic) and ascorbic acids, as well as traces of urea and of uric acid. The authors state that artificial sweat made according to their analysis and to those reported in the literature was fungicidal. The role of lactic acid in the fungicidal action of the sweat was demonstrated. Sebum found in the contents of sebaceous cysts was neither fungistatic nor fungicidal. The fungicidal properties of sweat are due to its content of acetic, propionic, caproic, caprylic, lactic and ascorbic acid. These substances must be present in the proper concentration to exert a fungistatic or fungicidal effect. There seems to be a relation between the localization of fungous infection and the distribution of sweat on the surface of the body. Areas which are exposed to the greatest concentration of sweat seem to have less tendency to fungous infection. Topical applications of ingredients of sweat, such as mixtures of lactic, propionic, butyric and ascorbic acid in proper concentrations, have proved valuable in the treatment of fungous infections.

**Animal Septicemia**—Nedzel and Pincussen studied the effect of ultraviolet and visible radiation on animals (white mice) infected with hemolytic streptococcus and irradiation of infected animals given bactericidal drugs for the purpose of studying their influence. One group of mice was not treated with any drug and another was given sulfanilamide mixed with food three

days before the hemolytic streptococcus was injected. Both groups were irradiated daily three days before the injections and daily thereafter. Two different sources of light were used: the mercury in quartz with its intense ultraviolet and some visible lines and the carbon arc lamp with its continuous ultraviolet and visible spectrum. The death rate of the infected but not otherwise treated mice rose relatively fast. In five days about 40 per cent of the animals were dead. This mortality rate was counteracted by the effect of irradiation, so that the percentage of deaths in those irradiated with quartz and carbon arc lamps dropped to 16 per cent. In the following days the death rate rose in all cases but less in the irradiated animals. The loss in weight of the surviving irradiated animals seemed to be higher in the beginning, but later they showed a better recovery. It is concluded that irradiation in these experiments has a beneficial effect. The animals given pitressin showed a favorable effect following irradiation. The death rate of mice infected with streptococci was cut in half irrespective of whether these were subjected to the mercury in quartz or carbon arc lamp. The loss in weight seemed a little greater in the carbon arc group. The few surviving nonirradiated animals did not show any loss of weight. Quartz lamp irradiation increased the death rate of the animals given sulfanilamide to a high degree in contrast to the carbon arc spectrum which did not depress the favorable sulfanilamide effect in the first few days. Later, however, the death rate is only about one half of that without irradiation. The effect of irradiation seems to be twofold: (1) physiologic effect on the blood vessels as in the pitressin experiments and (2) chemical effect, lessening the effectiveness of sulfanilamide.

**Serum Therapy for Streptococcal Infections**—Shepler and her associates treated thirty patients suffering from severe hemolytic streptococcus infection of the nose, ear or throat with streptococcus serum. Four of these cases were complicated by meningitis and in fifteen the blood yielded bacteria on culture. Three different kinds of streptococcus serum were used, together with other therapeutic measures (transfusions, sulfanilamide and bacteriophage in certain instances). There were seven deaths. Generalized meningitis with streptococci recognizable in the spinal fluid was present before serum therapy was initiated in three of the fatal cases. The authors have no evidence to indicate that established diffuse streptococcal meningitis can be controlled by the serum that they employed. In only one instance was there recovery after definite evidence of meningitis, and in this case, although the spinal fluid was clouded with abundant leukocytes, culture failed to disclose the

presence of streptococci in it. The other four deaths occurred in patients with streptococcal bacteremia but without meningitis. Among the twenty-three successful cases, streptococcal otitis media developed in two debilitated patients under treatment for staphylococcal osteomyelitis. One of the patients received serum, and the other received serum and sulfanilamide. There were two patients with mediastinitis and one with streptococcal empyema following pneumothorax for active pulmonary tuberculosis. In all three of these the activity of the streptococcus was adequately controlled. Two patients had streptococcal pneumonia complicated by voluminous empyema. One patient presented the classic symptoms and signs of septic thrombosis of the cavernous sinuses in the presence of a positive infection of the blood stream with hemolytic streptococci. Sulfanilamide, serum and bacteriophage all were brought into play in this case, with a successful outcome, apparently unique. The difficulties and dangers in the use of streptococcus serum are serious. For this reason streptococcus serum probably should not be used for streptococcal infections of moderate severity, which may be adequately controlled by the oral administration of sulfanilamide. When, however, a really grave situation arises in a case of streptococcal infection the proper use of the serum is definitely indicated. Certainly in the all too frequent streptococcal infections of the nose, throat, ear and mastoid the use of sulfanilamide or of serum or a combination of the two may be expected to control the infection and to obviate the necessity of surgical intervention.

**Intestinal Obstruction Due to Gallstones**—In the experience of Dulin and Peterson intestinal obstruction due to gallstones occurs with sufficient frequency to make it an important consideration in the diagnosis of acute abdominal conditions. This is particularly true when the patient has previously had typical attacks of gallstone colic. Also this type of obstruction may occur in a patient who has never had such an attack. The factors which make clinical diagnosis difficult are the similarity of the symptoms to those of an acute attack of gallstone colic and the lack of early physical or laboratory studies which would positively indicate the nature of the condition. In the authors' series of ten cases only three such diagnoses were made preoperatively. In one case a diagnosis depended on the disappearance of previously palpable stones in the gallbladder, in another a stone produced a negative filling defect in a flat teleroentgenogram. The diagnosis was made in only one case which presented the classic history of previous biliary colic followed by a sudden development of symptoms of acute intestinal obstruction. The authors believe that greater awareness of this condition and the more frequent use of the teleroentgenogram will aid in making not only more frequent preoperative diagnoses but earlier ones. While the teleroentgenogram may show only evidences of fluid levels within a dilated intestine, this observation is uncommon except when it is associated with paralytic ileus or mechanical obstruction. Diabetes mellitus was present in three of the ten cases. In two the diabetes was severe. In no instance, however, was it shown to contribute to the condition produced by the obstructing gallstone.

- Medical Economic Problems H. W. Sawyer Fallon Nev.—p. 20
- Tuberculosis in San Quentin L. L. Stanley San Quentin—p. 25

**Renal Function in the Aged**—Huffman determined the renal function of sixty-seven persons 70 or more years of age. Serious degrees of impairment of renal function is not necessarily an accompaniment of old age. True nephritis was rare in the present group of subjects and, while slight degrees of nitrogen retention were not unusual, the classic picture of uremia was infrequent. The data indicate the frequent association of renal impairment and prostatic hypertrophy. Twelve of fourteen male school teachers had some palpable enlargement of the prostate. The gradations from a symptomless enlargement to complete obstruction may be almost imperceptible. When evi-

dence of renal impairment exists in the male it is obligatory to rule out obstructive uropathy before a diagnosis of true nephritis is made. The presence of albumin and casts and fixation of specific gravity of the urine in either sex clearly indicates that other functional tests should be employed before any conclusions are drawn regarding the renal status. There is usually adequate function if the excretion of phenolsulfonphthalein approaches 40 per cent in the first fifteen minute specimen and 60 per cent in the two hour specimen. Likewise, when the value of the urea clearance test in percentage of normal is 70 or more, good renal function is usually present. When values of urea clearance are 50 per cent of normal, some impairment is present and values from 50 to 70 per cent should be considered doubtful and other tests of renal function employed. When clearance studies show values less than 25 per cent, a dangerously low level has been reached in the aged person. The level of the nonprotein nitrogen of the blood may be of significance in showing renal impairment. Elevated values are regularly found when the urea clearance is 20 per cent of normal. It is difficult to analyze the factor of blood pressure as related to renal function in the aged. It is probable that vascular narrowing in the renal bed, incident to advancing years, necessitates a physiologic increase in the general blood pressure to facilitate the work of the kidney.

\*Preliminary Report of the Prophylactic Use of Sulfanilamide in Patients Susceptible to Rheumatic Fever Caroline Bedell Thomas and R France, Baltimore—p 67

**Prophylactic Use of Sulfanilamide in Rheumatic Fever**—Thomas and France carried out studies to ascertain whether sulfanilamide might prevent the occurrence of rheumatic recrudescences in susceptible patients by controlling the antecedent streptococcal infections. Thirty patients were chosen from the Cardiac Clinic of the Department of Medicine of Johns Hopkins Hospital. During the first winter, 1936-1937, the entire group were given sulfanilamide. Actually, eighteen of those chosen proved cooperative and the remaining seven afforded a control series. During the winter of 1937-1938 nineteen patients received sulfanilamide, seven of these had been in the original treated group. Twelve new controls were added and the eleven patients who received treatment the first winter, but not the second, formed a control group of a different type. The ages of the patients ranged from 14 to 36 years. Fifteen grains (1 Gm) of sulfanilamide daily divided into three doses was prescribed from November 1936 to June 1937. During the second winter the dose was increased to 20 grains (1.3 Gm) daily divided into two doses and was given from October 1937 to June 1938. None of the patients had a major attack of acute rheumatic fever or an acute beta hemolytic streptococcus infection while taking sulfanilamide. Five major attacks of rheumatic fever developed in four of the thirty control patients during the same period, one was hospitalized because of an acute beta hemolytic streptococcus

infection and three others had acute illnesses which might have been of a rheumatic character. The group studied is too small to permit definite conclusions, but the authors believe that their results are encouraging and warrant further investigation.

**Pyuria in Childhood**—Helmholtz states that sulfanilamide acts best in an alkaline urine. It is well to give from 10 to 15 grains (0.65 to 1 Gm) of sodium bicarbonate three times a day with the sulfanilamide in order to prevent acidosis. The dose of sulfanilamide that he has found to be sufficient in most cases of pyuria in childhood is 10 grains to 20 pounds (9 Kg) of body weight, if necessary the dose may be increased to 15 grains, as recommended by Long in the treatment of streptococcal infection. For short periods the dose may be increased to 20 grains (1.3 Gm) to 20 pounds of body weight. It is possible further to increase the urinary concentration of sulfanilamide without increasing its concentration in the blood by cutting down on the intake of fluids. The administration of large amounts of fluids and alkalization of the urine have been the standard treatment in acute cases of pyelitis, especially in infancy. In addition to this routine treatment, sulfanilamide can be given advantageously every four hours in the foregoing dosage. With the addition of sulfanilamide to the scheme of treatment the acute symptoms, high fever and restlessness may disappear at an earlier time than usual. Administration of the drug should be continued in the same dosage until there is no evidence of bacterial growth in a culture of the urine and continued for from four to six days after the urine has become sterile. If, at the end of a week the urine on culture is still sterile one may be quite certain that the patient has been cured. If the urine again shows bacteria, it must be assumed that bacterial growth in the urine was merely inhibited and that further treatment is necessary. Instead of 10 grains, 15 grains of sulfanilamide to 20 pounds

of body weight should be tried and the same process repeated. It is advisable in such cases to continue the same dosage for from eight to ten days after the first culture of sterile urine is obtained. Four days after discontinuation of the medication, the urine should be checked again. The same procedure is carried out in cases of subacute and chronic infections, with the exception that no effort is made to force fluids. A rapid recovery from both acute and chronic infections is likely when the infecting organism is a gram negative bacillus, *Escherichia coli*, *Aerobacter aerogenes*, *Salmonella*, *Proteus vulgaris* or *Proteus ammoniae*. The same applies to staphylococcal infection of the lower portion of the urinary tract. The excellent results obtained in treating infections with the bacillus *Proteus ammoniae* (encrusted cystitis) should be emphasized because it, in particular, has been resistant to methenamine and mandelic acid therapy and to the ketogenic diet. Since the author has used sulfanilamide it has become evident that *Streptococcus faecalis* is a much more frequent invader of the urinary passages than he had formerly realized. How frequently mixed infections occur should become evident with the continued use of sulfanilamide. If there are many, the success of sulfanilamide therapy will be decreased and this will necessitate treatment by means of a combination of sulfanilamide and mandelic acid. In the treatment of urinary infections by means of mandelic acid it is advisable to continue treatment for three or four days after a culture of urine has become sterile. Administration of the drug may then be discontinued and, after another interval of three or four days, the culture should be repeated, a sterile culture then indicates cure. Treatment by means of sulfanilamide is easier to carry out than is treatment by the ketogenic diet, methenamine or mandelic acid. It is successful in urine which is alkaline because of urea-splitting organisms, and it is successful in conditions in which the function of the kidney is reduced. Sulfanilamide is of no value in the treatment of infections with *Streptococcus faecalis*. Mandelic acid is of value in the treatment of all infections in which the urinary acidity can be reduced below 5.5 and the drug excreted in a concentration in 0.5 per cent.

**Exposure of Body to Unequal Temperature**—More has noticed that many typhoid patients and children with pneumonia were those occupying beds or cribs placed so that the temperature on either side was uneven. For example, one side of the bed was next to a window with a source of heat coming from the other side. So emphatically was it impressed on the author that unequal temperature is an etiologic factor in pneumonia that, when building a small hospital, he had the windows and doors to the rooms and wards placed opposite each other, leaving ample wall space for beds without exposing the patients to unequal temperature. Pneumonia has never developed in patients entering the hospital early with typhoid and free from lung complications. At one time during an epidemic of typhoid the hospital ward was overcrowded and a patient occupying a bed next to a wall 22 feet from a double window was observed to be coughing. While examining the patient, the author distinctly felt a draft of air on the back

of his head and neck. There was a breeze coming through the top of the windows 22 feet away and was directed toward the ceiling by a contrivance at the top. The wind followed the ceiling and continued down the wall where the patient was. His position was immediately changed and he recovered promptly. The author has a patient who will sneeze if he leaves a warm room and walks outside while a cool breeze is blowing, and his nose will begin to discharge. But if he will turn round so that all parts of his chest are cooled equally, this condition soon stops. Some people are more susceptible to this unequal temperature than others. In children with pneumonia whose parents can not or will not protect them from unequal temperature, the pneumonia jacket, frequently changed, is most useful, chiefly it is believed because it maintains an equal temperature. Those advocating cold fresh air for children with pneumonia place them in cold rooms. Here the patient gets the benefit of the fresh air without exposure to unequal temperature. The author concludes that exposure of the body to unequal temperature is a predisposing etiologic factor in pneumonia as well as the cause of so-called "colds in the head," coryza, tonsillitis, pharyngitis and the like.

**Vaccines in Treatment of Allergy and Asthma**—Ylvisaker used autogenous streptococcus vaccines in the treatment of bacterial or infectious types of allergy (including fourteen cases of bronchial asthma, four of allergic rhinitis and one each of recurrent sinusitis, generalized eczema, chronic urticaria, conjunctivitis and iritis). The initial dose of vaccine varied from 25,000 to 100,000 organisms. Injections (fifteen intravenously and eight subcutaneously) were given from every three to five days. As the patient improved, the interval was lengthened to from five to seven days. The size of the dose was gradually increased until definite improvement was noted. No further increase was made as long as improvement or relief of symptoms was maintained. Any reaction following a dose called for a marked reduction in the next dose. If possible, the injections were continued over a period of at least six months so as to prevent recurrences. In several cases they have been continued for periods of from two to three years, with occasional rest periods of from six to eight weeks. Seventeen of the twenty-three patients treated obtained complete or nearly complete relief. Three cases of bronchial asthma failed to improve. The beneficial effects produced by the minute doses are probably due not to a foreign protein shock therapy but rather to a specific type of desensitization. The intravenous route of administration produces more prompt and precise results than the subcutaneous route. Severe reactions may be expected following intravenous administration if too large doses are used or too long an interval is allowed to elapse between doses. The beneficial effects of vaccines in allergic states, especially asthma, are not confined to the primary bacterial allergies but may also be of value in certain cases in which bacterial allergy is secondary.

**Electrocardiogram in Vitamin B<sub>1</sub> Deficiency**—Dustin and his associates discuss six male patients with histories of unbalanced diets and clinical evidence of vitamin B<sub>1</sub> deficiency. All these patients showed abnormal electrocardiograms. They gave a history of the habitual use of alcoholic beverages,

usually beer, and concurrently a deficient diet. All entered the hospital because of swelling of the legs and some dyspnea. Two also had swelling of the abdomen. Only one patient complained of substernal discomfort. All but one patient received a diet high in vitamins and all received vitamin B<sub>1</sub> medication. In two the cardiac sounds showed notable changes with treatment, in one of these a gallop rhythm disappeared soon after entrance. In three there was a marked reduction in the size of the heart as treatment progressed. Only one patient had definite anemia, hypochromic in type, and this responded to treatment during the hospital stay. All patients lost from 8 to 28 pounds (3.6 to 12.7 Kg.) concurrently with the reduction of the edema. Only one patient received digitalis in addition to vitamin therapy. Electrocardiograms at rather close intervals were taken of each patient while he was under treatment. The common features seen on admission were increase in the electrical systole, according to Bazett's formula, a rapid rate and a tendency to low voltage, and in most cases a flattening of the T wave in leads 1, 2 and 3. The chest leads showed the least tendency to become abnormal. Subsequent records during treatment showed a slowing of the rate, an increase in the voltage and varying changes in the ventricular complexes. The changes in the ventricular complexes during treatment usually occurred within a few days. As treatment progressed, during the first week or two the electrocardiograms became more abnormal and then tended to return toward normal. The abnormal ventricular complexes changed more rapidly than would be expected in coronary disease. The changes in the T waves, as described, may be caused by several conditions, therefore it is necessary in interpreting electrocardiograms to know the existent clinical conditions.

**First Allergic Manifestations in Infants.**—Clein observed 100 allergic and 100 nonallergic infants, from private practice, from birth to 4 or 5 years of age. The feedings, examinations and observations were uniform in all infants. Seventy-one per cent of the allergic infants had allergic parents, 12 per cent of the nonallergic. Of the allergic infants 78 per cent showed some allergic symptoms before 4 months of age, 91 per cent by 1 year and 100 per cent by 2 years as follows: (1) rash (eczema) in eighty-five cases, occurring chiefly on the face, (2) vomiting (pylorospasm) in twenty-four and (3) colic (abdominal pain, gas or diarrhea) in sixteen. One or more of these symptoms were frequently present at the same time. The author suggests that egg yolk should not be added to the diet of allergic infants too early, as many are sensitized through the mother's milk or inherit the sensitivity. Specific attention to the diet and the environmental factors during childhood may prove to be important prophylactic measures in preventing or minimizing the major allergic diseases.

**Prevention of Recurring Herpes.**—Ever since his experiments with laryngeal papilloma and warts (1920-1923) Ullmann has wondered about the odd phenomenon that laryngeal papilloma, as well as most forms of warts, disappear at some time without any therapy. Warts and laryngeal papilloma are classed as diseases due to a filterable virus and show histologically inclusion bodies, as do all forms of herpes. The author cites four cases of recurring herpes which ceased to recur after vaccination for smallpox. He is at a loss as to whether this is a phenomenon of immunization or one of suggestion.

**Diabetic Manifestations in Ophthalmology.**—Smith discusses some of the ocular manifestations of diabetes. One of the more rare manifestations is that of lipemia retinalis. Moore of London states that he has not seen such a case since the introduction of insulin. Retrobulbar neuritis is usually found in older persons, is characterized by a small central scotoma and usually responds to treatment. If the condition is allowed to progress there may be some resulting atrophy. Iritis demonstrates the lack of resistance to infection which diabetic patients show. There are more often changes in the pigment cells on the posterior surface of the iris. They become swollen, thus throwing the iris into more prominent folds. The cells often become detached and may be found on the anterior surface of the lens. The majority of so-called diabetic cataracts are nothing more than ordinary senile cataracts developing in patients with diabetes. The true diabetic cataract is found in young persons, is bilateral and develops rapidly. It is characterized by flaky lesions which develop faster in the posterior layers of the cortex. Senile cataracts tend to develop earlier in diabetic than in nondiabetic persons. Likewise retinitis is somewhat similar in that in the vast majority of cases in which it develops there is usually associated a raised blood pressure, vascular disease and albumin in the urine. Often it is difficult to state from ophthalmoscopic appearances whether a given case of retinitis is due to diabetes, nephritis or arteriosclerosis. Wolfe states that there are certain characteristics of a true diabetic retinitis: 1. It rarely occurs in a young subject. 2. The patches of retinal exudate tend to have sharply defined edges, are distributed in an irregular manner and sometimes form an irregular ring around the macular region. 3. Small dark round retinal hemorrhages are suggestive of diabetes. As such they lie in the deeper layers of the retina. With regard to prognosis, Nettleship found that of forty-eight patients with diabetic retinitis 60 per cent lived for more than two years. Thus it is an indication of some gravity but is not as serious a sign as retinitis in renal disease. Hemorrhage is more apt to follow surgery of the eye in a diabetic than in a nondiabetic person. Changes in refraction are common. The exact mechanism for this is not known, but it may be due to an alteration of the osmotic pressure in the aqueous humor. This in turn causes an altered index of refraction of the lens cortex. It may cause myopia in some cases while in others hyperopia may develop. It may appear shortly after the beginning of insulin therapy. The author cites such a case.

**Vitamin C and Poliomyelitis**—Hershup states that toward the end of 1937 an epidemic of poliomyelitis began in South Australia. A number of the earlier cases occurred in an area of a city in which immunization against diphtheria had been carried out previous to the epidemic, and Dwyer observed that the majority of the cases of poliomyelitis occurred in children non-immunized to diphtheria. Immunization had been carried out without previous Schick testing. In 1937 Jungblut reported that vitamin C had a therapeutic effect when injected subcutaneously into monkeys inoculated with the virus of poliomyelitis. A review of the literature on susceptibility to diphtheria and to poliomyelitis showed in each case a correlation with the results of certain experimental work with vitamin C. In 1917 Zingher reported that a positive reaction to the Schick test was given in a disproportionately large percentage of cases of poliomyelitis. Comparing the patients with poliomyelitis who were not immunized to diphtheria with the controls, the author finds that the age group of 12 years and over gives substantially the same percentage of positive Schick reactions as the control group. This is possibly the most extraordinary result obtained, as this age group contains 42 per cent of the patients and their ages range up to 60 years, 30 per cent of them are 21 years or more of age. Admitting that some of these are rural dwellers, the figure is still high in a state in which diphtheria is moderately prevalent. The same may be said of the whole group especially when it is considered that fewer than a third of the patients are less than 6 years of age. Of the 238 patients tested twenty-one had been artificially immunized and nine had had diphtheria. Eight of these thirty gave a positive reaction to the Schick test. In a control group of 359 persons, of whom four had had diphtheria and 355 had been artificially immunized, only two gave a positive Schick reaction. One of these had received only 0.5 cc. of anatoxin and the other only 1 cc. The author is tempted to suggest that the latter result is due to the fact that those who remained Schick positive after immunization contracted poliomyelitis. These figures support the idea of a constitutional defect underlying susceptibility to the two diseases, and it is not surprising to learn that several of the patients with poliomyelitis here, within a few months, contracted diphtheria despite immunization. Dwyer has reported that few of these immunized patients contracted poliomyelitis. This contrasts sharply with the report of Henry and Johnson that 51 per cent of their patients with poliomyelitis had been previously immunized. The explanation is probably that Dwyer's group was immunized without previous Schick testing, that is to say, many of them did not require it, whereas it is justifiable to assume that all of the latter group were Schick positive prior to immunization. From these results, supported as they are by Zingher's observations on a much larger group, it is evident to the author that there is a greater susceptibility to poliomyelitis in persons giving a positive Schick reaction than in those who give a negative reaction. Conversely there is a larger percentage susceptible to diphtheria among those who contract poliomyelitis than in the normal population. The urinary excretion of vitamin C from various groups of infected and noninfected persons has been estimated and the conclusion is drawn that, while the usual sequence of events is a decreased excretion of vitamin C following infection, it is probable that a low level of vitamin C nutrition predisposes to infection and severity of attack. It is probable that there is a relationship between nutrition and the age incidence in this disease.

**Production of Uterine Hemorrhage by Progesterone**—Zondek and Rozin learned that if progesterone is administered to normally menstruating women for five days during the post-menstrual stage (seventh to twelfth day of the cycle) bleeding of several days' duration occurs after an interval of sixty hours on the fourteenth day of the cycle. Since the uterine mucosa in this stage does not show any of the secretory stage or only the beginning of it, this hemorrhage can be looked on as pseudo-menstruation. The normal ovarian cycle need not be disturbed by this event. If progesterone is administered at the time of the follicular rupture, at a moment when the patient has her own corpus luteum, bleeding either does not occur at all or there is a hemorrhage from a mucous membrane already developed into the premenstrual stage. In this case precocious menstrual bleeding can be induced. The authors also observed that treatment with progesterone for five days can produce hemorrhage in secondary amenorrhea without preliminary treatment with estrogenic substance. In primary amenorrhea, however, such treatment fails. Since it had become evident that progesterone could induce hemorrhage in the normal as well as in the disturbed ovarian cycle, the authors tried to initiate hemorrhage during pregnancy in order to bring about therapeutic abortion in this way. They used doses of from 50 to 150 mg of progesterone. Bleeding, however, did not occur and pregnancy continued.

**Puerperal Cervicitis**—Arthure states that it is of great importance to treat cases of cervicitis early, before the lesion has become chronic and deep seated. The infection is due to a nonhemolytic streptococcus but the essential cause of the lesion is trauma and the histologic aspect of puerperal cervicitis is identical with that of ectropion. The most frequent single factor responsible for this trauma is early rupture of the membranes, which is therefore inadvisable as a method of inducing labor. Treatment by cauterization can be carried out as an outpatient method without special preparation or after treatment. The author obtained satisfactory results in fifty-six of sixty cases of cervicitis treated by cautery. Partial failure may be due to inadequate treatment of the endocervicitis, which is probably present in all cases. Cauterization is far more efficacious in recent cervicitis than in cases of long standing, in which the infection is no longer superficial.

**Properties of a Synthetic Estrogen**—Bishop and his co-workers administered a synthetic estrogen (stilbestrol) to eighteen patients with amenorrhea of variable duration "Estrogenic withdrawal bleeding" was provoked in eight, and rhythmic uterine hemorrhage occurred during the period of administration in two. Of the patients who did not respond by uterine bleeding, one had previously failed to respond to the administration of natural estrogens and one had received no previous estrogenic therapy. The amenorrhea in this patient was of eight years' duration, the onset having accompanied that of anorexia nervosa. Six patients failed to respond to the synthetic estrogen though previous courses of theolol (estradiol benzoate) had resulted in withdrawal bleeding. Of the ten treated successfully, three had received no estrogen previously but responded to such low doses as 14 mg or less given by mouth. In fifteen patients with the menopausal syndrome and in ten with atrophic conditions of the vagina symptomatic relief (especially with regard to the daily frequency of hot flushes), vaginal smear pictures and improvement of the local condition (of the vagina) were taken as the main criteria of response. Of these twenty-five patients, eight failed to respond to the administration of the synthetic substance. Five of these received relatively small doses, totaling 28 mg or less, though three of these had reacted satisfactorily to lower doses of ethinyl estradiol (a partially synthetic compound of natural estrogen). Of the remaining three, two were suffering from atrophic vaginitis, neither had received previous estrogenic therapy and with both there was doubt as to whether the local condition was due to ovarian deficiency. The third patient failed to react to small doses of ethinyl estradiol. Of the successfully treated patients, one reacted to 0.1 mg given by mouth daily for a fortnight both symptomatically and with the production of an estrous smear (though the improvement was not maintained after a further course). Another patient failed to respond to doses of 0.1 mg but reacted satisfactorily to 1 mg doses both as to the fortnightly hot flushes and the vaginal smear. In all the other subjects doses of 1 mg or more produced satisfactory responses. Symptomatic improvement was almost always associated with a transformation of the vaginal smear to the estrous type. Two patients with dysmenorrhea were completely relieved by the daily administration of 1 mg tablets of the synthetic substance during the first half of the cycle. They had experienced similar relief from four injections of 5 mg of estradiol benzoate. Nausea or vomiting occurred in three cases. The authors do not believe that these symptoms depend on the dose given.

**Gout Following Salyrgan Diuresis**—Although mentioned by Hench (1936), the occurrence of gout after the use of salyrgan for the relief of edema in congestive cardiac failure does not appear to be widely recognized. Price reports five such cases and believes that the fact that they were observed within a period of little more than a year suggests that the association of salyrgan and gout cannot be uncommon. In all five cases salyrgan was given intramuscularly in doses of 1 cc on alternate days and supplemented by 13 Gm of ammonium chloride given three times a day by mouth. All the patients were kept strictly at rest and on a reduced intake of fluid. The onset of gout following the use of salyrgan in cases of cardiac failure is of grave prognostic significance. It seems to be usual for patients to succumb within a few weeks of the attack. It may be that gout develops only after forced diuresis in patients in the terminal stages of cardiac failure, or gout may have some deleterious effect on the cardiac condition. This raises the question of the desirability of using mercurial diuretics like salyrgan when there is a history of previous gout, since it seems possible that too successful a diuresis may be dangerous.

**Alcoholic Beriberi**—Following remarks about the effects of an insufficiency of vitamin B<sub>1</sub> in beriberi, Van Bogaert calls attention to the relationship between alcoholic polyneuritis and deficiency in vitamin B<sub>1</sub>. He gives a detailed report of the clinical history of a man aged 28 who entered the hospital with the diagnosis of myocardial insufficiency. The circulatory disorder was characterized by dyspnea, stasis in the jugular veins, hepatomegaly, generalized edema and pleural effusion. The heart was greatly enlarged and presented severe electrocardiographic changes. Moreover, the patient had a polyneuritis localized in the inferior members. The anamnesis revealed that, two years before, the patient had undergone a partial gastrectomy on account of a pyloric ulcer. For the last six years he had consumed daily large quantities of alcohol. He received neither diuretic nor cardiotonic medication but in addition to an ample diet was given daily an intramuscular injection of 10 mg of crystallized vitamin B<sub>1</sub> (5,000 international units). Under the influence of this treatment the diuresis increased, edema disappeared within six days and the pulse became slower. From the tenth day of the treatment the x-ray image of the heart was practically normal. In the course of the following week the dyspnea disappeared entirely and the liver was no longer palpable. At the end of this week the muscular pains in the legs had entirely disappeared and the patient was able to get up, walk around and even mount stairs without signs of dyspnea. The patellar reflexes were now normal but the achilles tendon reflexes were still abolished. After the patient had been in the hospital for three weeks the dose of vitamin B<sub>1</sub> was doubled, that is, two injections of 10 mg were given daily. This was done in the hope of restoring the electrocardiogram to normal outlines. However, when this supersaturation with vitamin B<sub>1</sub> had only a slight effect and a nervous factor in the abnormal electrocardiogram could be excluded, other tests were made and it was found that the basal metabolism was below normal. When this was discovered, treatment with thyroid was instituted and was continued even after the patient had been discharged from the hospital as apparently cured. In commenting on this case the author first estimates the mode of development of the B<sub>1</sub> avitaminosis and shows that it was not primary, as is the case in Asiatic beriberi, but rather secondary, that is, it was caused by defective assimilation. In this connection he estimates the possible importance of gastrectomy, hepatic lesions and alcoholism. After discussing the divergences which exist between the neurocirculatory syndrome of Asiatic beriberi and that of the secondary avitaminoses, he estimates whether the thyroid was involved in the electrocardiographic modifications of the reported case. He points out that the thyroid stimulates the general cellular exchange, even that of the myocardium, and that the electrocardiographic disturbances in B<sub>1</sub> avitaminosis seem to be the manifestation of a slackening of the intramyocardial cellular exchanges.

- \*Hypertrophy of Thymus in Course of Acute Leukemia of Children R Pierret, L. Christaens and Popoff—p 5
- Prophylactic and Therapeutic Value of Placental Globulin Extract in Measles Scarlet Fever and Mumps Mathilde de Biehler—p 29
- Relapsing Infectious Encephalitis L. Nove Josserand G Bertrand and Mlle. M. Flotard—p 34

**Hypertrophy of Thymus in Acute Leukemia**—Pierret and his associates say that in a comparatively short time they observed three children in whom acute leukemia was accompanied by hypertrophy of the thymus. They report the clinical histories of these three children, who varied in ages between

6 and 10 years. Then, following a review of the literature, they discuss the problem of concurrence of thymic hypertrophy and leukemia and reach the following conclusions: 1. There exists a clinical form of leukemia, which affects mainly children and which is characterized by the presence of a hypertrophy of the thymus. The hypertrophy of the thymus is not accompanied by clinical signs that are usually ascribed to this anatomic manifestation. In one of the described cases in which the necropsy revealed a thymus weighing 200 Gm. there were no inspiratory effort, no roaring sound and no dyspnea. The authors find it difficult to subscribe to the opinion of certain investigators who make thymic hypertrophy the "primum movens" of the disease, that is, who suggest that the cells issue from the thymic tumor and then pass into the circulation. They, on the contrary, think that the invasion of the thymus is secondary to the leukemia. The clinical factors that are of especial importance in this particular form of leukemia are (1) its extreme gravity and the superacute character of its evolution and (2) its extraordinary sensitivity to roentgen rays, which demands the greatest prudence in the utilization of roentgen therapy. From the diagnostic point of view, two points deserve to be stressed: (1) If roentgenoscopy indicates the existence of a tumor of the thymus, it is necessary to make a systematic examination of the blood and (2) it is advisable to make a careful roentgenologic examination in all cases of acute leukemia before roentgen therapy is instituted. It is not sufficient to relate observed shadows to mediastinal adenopathies, but it must be ascertained whether certain characteristics do not permit to connect these shadows to the thymus. In an addendum to this report the authors say that they observed a fourth case of enormous thymic hypertrophy in a child aged 4 who had leukemia. This child was hospitalized in a moribund condition. The necropsy favored the diagnosis of lymphoid leukemia, for it revealed a remarkable lymphoid infiltration of all organs. The thymus was of enormous size and it was entirely infiltrated with lymphocytes; Hassall's corpuscles were absent. The authors think that thymic infiltration is perhaps more frequent than was thought in the course of acute lymphoid leukemia of childhood, constituting a particularly severe form of the disease.

\*Choreas of the Aged. R. Pauly.—p. 239

Temporoparietal Disorientation and Preponderance of Right Hemisphere in Proprioceptive Agnosia-Alexias. M. Dide.—p. 276

**Choreas of the Aged**—In this report on the choreas of the aged, Pauly first gives a historical review of the literature and then presents anatomoclinical studies on the different forms of chorea that appear in aged persons. In persons over 60 it is possible to observe generalized and localized choreas, chronic, acute and subacute choreas, and primary and secondary choreas. The chronic generalized choreas of the aged are rarer than the choreas of Huntington, that is to say, the choreas due to a heredodegeneration. Much more frequent are the nonhereditary choreas. These choreas may be accompanied by mental disorders of the dementia type. Regarding the etiology the author says that in exceptional cases they are of syphilitic origin, sometimes they are arteriosclerotic, but usually they present anatomopathologic aspects much like those of Huntington's chorea. The chronic hemichoreas fit into the framework already established for the choreas of adults. They may be localized in the putamen-caudate region, in the nucleus of Luys or in the pedunculo-cerebellar region. Softened and hemorrhagic foci are the usual cause. Truly acute chorea may also develop after the age of 60. When this form has the antecedents of Sydenham's chorea or of acute articular rheumatism, some authors regard it as a relapse, that is to say, as a reactivation of the causal organism. Nevertheless, acute chorea can also be primary. It is more often generalized than localized, it is rarely accompanied by cardiac lesions and it has a tendency to relapses and to chronicity. Discussing the etiology of the latter form the author does not hesitate to concede the existence of a chorea of Sydenham in spite of its classic predilection for young persons. However, an anatomoclinical observation and experimental studies by Harvier and Decourt prove the existence of choreas provoked by a neurotropic virus comparable to that of epidemic encephalitis if not identical with it. Besides these acute choreas of the Sydenham

type there develop also subacute choreas with relapses, choreas which Lhermitte designates as intermittent. The author reports a case illustrating this type. Certain arguments militate in favor of a formal distinction between this intermittent form and the chorea of Sydenham. Discussing the anatomic aspects of the choreas of the aged, the author says that they are complex and diverse: there may be cortical and striatal lesions, lesions of the body of Luys and subthalamic ones, and lesions of the superior cerebellar peduncle. In each of these regions the eliciting causes are found to be multiple. However, whereas in the superior cerebellar peduncle the disintegration is usually of vascular origin and whereas in the body of Luys and in the subthalamic region softening is predominant, in the cortex and the central gray, on the other hand, there may be vascular or infectious lesions and cellular degeneration.

\*Grave Postoperative Attack of Paroxysmal Tachycardia Treated Successfully by Procainization of Left Stellate Ganglion. R. Leibovici, L. Dinkin and Wester.—p. 83

**Injection of Stellate Ganglion for Paroxysmal Tachycardia**—Leibovici and his associates report the clinical history of a man aged 29 who developed a severe form of paroxysmal tachycardia after an appendectomy. Since energetic medication was without effect on the tachycardia, it was decided to arrest the tachycardia by injecting procaine hydrochloride into the left stellate ganglion. About 20 cc. of a 1:200 solution of procaine hydrochloride was injected slowly. The effect was immediate. The pulse fell suddenly from 180 to 72 and the patient felt greatly relieved. In the minutes which followed the injection, Bernard-Horner's syndrome developed and persisted for several hours. This confirmed that stellate blockage had been accomplished. The pulse remained normal (always around 76 to 80). The further course was uneventful and the patient was discharged on the eighth day. Four weeks after the intervention an examination of the heart revealed nothing abnormal. The patient never had another attack of tachycardia. The authors cite factors which indicate that this was a case of paroxysmal rather than of sinus tachycardia and then point out that it is no longer disputed that the sympathetic plays a part in sinus tachycardia and that surgical interventions on the sympathetic have been employed with good success in a number of cases of sinus tachycardia. In a table they list a number of cases of sinus tachycardia and the surgical interventions that were employed (sympathectomy on the left side, section of the efferent branches of the stellate ganglion, stellectomy on the left, right or both sides, hemithyroidectomy and so on). In a second table they list cases of paroxysmal tachycardia and the various surgical treatments employed in them (stellectomy on the left or right side and injection of procaine hydrochloride into the stellate ganglion). Further they show that interventions on the right stellate ganglion are effective in sinus tachycardia and interventions on the left stellate ganglion in paroxysmal tachycardia. Their own observation as well as that of Mandl indicates that merely infiltration of the stellate ganglion, without stellectomy, may produce favorable results not only immediately but also permanently.

How Long Does Test Serum Retain Agglutination Capacity? R. Meyer Wildisen.—p. 74

\*Further Cases of Spontaneous Poliomyelitis in Domestic Animals (Hogs). E. Frauchiger and W. Messerli.—p. 74

**Familial Leukemia**—Laub cites authors who have published reports about the familial occurrence of leukemia and describes the clinical history of a woman aged 26 who was under his observation and who died of myeloid leukemia. Investigating the etiology of this case he gave special attention to the family history and found that, fifteen years before, the patient's mother had died (aged 32) of the same comparatively rare blood disease, myeloid leukemia. Discussing this familial occurrence, he points

out that other investigators have raised the question whether the familial concurrence is merely accidental or whether hereditary factors play a part. Naegeli and Petri regard an accidental concurrence as most likely. Petri, for instance, finds no proof either in the literature or in his own observations that the appearance of leukemia in related persons is connected with hereditary factors. In contradistinction to Petri, Curschmann believes that the familial concurrence of leukemia is not merely accidental and that, although the question is not definitely solved, further investigations on the families of patients with leukemia might reveal signs of hereditary changes and susceptibilities of the blood forming organs. He, like Morawitz, rejects the theory of the infectious origin. The author thinks that his observation seems to support the opinion of the latter authors, namely that the familial occurrence of leukemia is not accidental but due to hereditary factors.

**Spontaneous Poliomyelitis in Hogs**—Frauchiger and Messerli say that since acute anterior poliomyelitis has been observed in cattle they have given special attention to paralytic symptoms in domestic animals. In this report they describe observations on two hogs which presented symptoms that greatly resembled those of acute anterior poliomyelitis. On the basis of these symptoms the disorder was diagnosed as probable poliomyelitis. Both animals were killed and the microscopic examination of the spinal cord revealed in both of them histologic aspects resembling those of acute anterior poliomyelitis in human subjects. Material from the spinal cords of these animals was introduced into two other hogs and into one steer. Because of an inadequate technic, nothing could be learned from the inoculation test on the hogs, but the steer, in which a formerly devised technic was employed for the inoculation, developed fever, the curve of which showed the dromedary type. Other symptoms included signs of fatigue, stiffness of the neck, and an atactic walk. From the seventh day after the inoculation the symptoms commenced to subside and a few days later the animal seemed normal again. The animal was killed fourteen days after the inoculation. The histologic aspects of the central nervous system were those of lymphocytic meningo-encephalomyelitis rather than those characteristic for poliomyelitis, but it must be remembered that the animal was not killed during the acute stage, when signs more typical for poliomyelitis might have been detected. However, since Spielmeyer's investigations demonstrated that similar histologic aspects do not necessarily indicate the same disease, etiology or causal agent, the authors do not definitely conclude that the described paralytic symptoms in hogs are identical with human poliomyelitis, but they do believe that this could be the case. They think that the detection of further cases of poliomyelitis in animals, the transmission from animal to animal and from man to animal, will provide more certainty.

### Gazzetta degli Ospedali e delle Cliniche, Milan

59 1255 1276 (Dec 18) 1938

\*Roentgen Irradiation of Hemopoietic Tissues in Normal Persons and in Those with Blood Diseases. A. Bertola, M. Ravetta and C. Zelaschi.—p 1255

Identification of Chronic Peritonitis Incapsulans with Hernia of Peritoneal Fossa. R. Babini.—p 1261

**Bone Marrow and Roentgen Irradiations**—Bertola and his collaborators studied the modifications of bone marrow from roentgen irradiations on the spleen, the sternum or other bones, or on the enlarged lymph nodes. The observations were made on four normal persons, eight patients with myeloid or lymphatic leukemia and two patients with malignant lymphogranuloma. They were applied every other day in small doses (from 210 to 630 roentgens in normal persons and from 60 to 150 roentgens for each treatment). The total number of treatments is not specified by the authors. In all cases bone marrow for microscopic study was taken by sternal puncture, before and after administration of the treatment. The irradiations caused no change in the erythroblastic tissues in normal persons or in the patients. They had a slight effect on the granuloblastic tissues of normal persons and a favorable action on the granuloblastic tissues of the patients. The proliferation of erythroblasts (ratio leukoblasts erythroblasts) and the curves of maturation and karyokinesis did not change in normal persons. In leukemia and malignant granuloma the production of erythroblasts did

not change. In leukemia the ratio leukoblasts erythroblasts improved or became normal from retarded production of granuloblasts. The curves of cellular maturation and karyokinesis improved (diminished mitosis, diminished prophase and increased telophases). The irradiations induced slight variations on the curves of cellular maturation in malignant lymphogranuloma. The number of lymphocytes in the bone marrow in cases of lymphatic leukemia diminished after the treatment. As a rule the myelogram in leukemia shows predominance of immature leukoblastic cells (myeloblasts or promyelocytes) before roentgen treatment and predominance of mature cells (myelocytes or myelometamorphocytes) or else a normal aspect after the treatment. The favorable modifications of the myelogram are induced by irradiations either of the bones or of the spleen. In one case of myeloid leukemia and a case of lymphatic leukemia, favorable changes of the bone marrow were induced from irradiations only of the spleen. The authors' attention was called to the pathogenic role of the spleen in leukemia and on the therapeutic value of roentgen irradiations on the structure. According to the authors the roentgen treatment is of value in these blood diseases, especially in leukemia, in which it controls the dysfunction of the hemopoietic organs which causes the disease. The article is a preliminary report.

\*Evolution of Primary Tuberculous Infection in Infants. J. Rodriguez Betancourt.—p 11

Rupture of Kidney in Child. Case. J. Garcia Romeu.—p 25

**Primary Tuberculous Infection in Infants**—Rodriguez Betancourt followed the behavior of primary tuberculous infection by means of x-ray studies of the thorax in a group of 250 infants. The infection developed in the following forms. In seventy-two cases there was tracheobronchial tuberculous adenopathy, in 131 there was pulmonary parenchymal infiltration, in thirty-six there was unilateral or bilateral bronchopneumonia and in eight there was caseous pneumonia. The lesion regressed in 182 infants, forty are still being treated and twenty-eight died. Tuberculous meningitis is the most frequent complication of the grave forms. As a rule the lesions of primary infection heal and the patient remains allergic. The evolution of acute or chronic forms depends on how long the patients are permitted to remain in tuberculous environments. An early diagnosis is important. It must be followed by (1) their separation from the tuberculous contact, (2) establishment in good hygienic quarters with proper diet and (3) early administration of treatment. It is advisable to follow the evolution of the tuberculous lesion by means of repeated x-ray examinations of the thorax. Artificial pneumothorax is indicated in acute and subacute forms.

**Adrenal Cortex and Obesity**—Bomskov and Schneider point out that investigations by Verzar revealed that the bilateral extirpation of the adrenal cortex results in the complete cessation of fat resorption, that the administration of adrenal cortex extract will restore the fat resorption but will not increase it above the normal values, and that yeast can be substituted for adrenal cortex extract. In their own studies on the role of the adrenals in fat metabolism the authors observed that the length of survival of rats or mice following bilateral extirpation of the adrenals is dependent on the age of the animals, infantile rats and mice all die within a few days after the extirpation, whereas adult animals show two different types of reactions. One group dies with the signs of cachexia, while the other group survives indefinitely. The authors describe studies on these two groups.

of animals. Summarizing their observations, they say that about half of the animals develop cachexia, which results in death after from thirty to thirty-five days. The fat reserves of these animals decrease greatly. Microscopic studies disclose no remnants of cortical tissue and the thyroid is unusually active. The symptomatology is probably the result of the abolishment of the cortical function and secondarily of the activation of the thyroid. In the other animals, which survive indefinitely, an increase in weight can be observed which is the result of great fat deposits. The rats become grunts, weighing 350 Gm and more (normal weight from 200 to 250 Gm). The necropsy disclosed in all of these grunt animals accessory adrenals consisting entirely of cortical tissue. These accessory adrenals greatly exceed the removed organ in mass and it is concluded that the cause of the obesity of these animals is a hyperfunction of the adrenal cortex. Microscopic examination of the thyroids of the grunt animals disclosed a state of complete quiescence.

**Exercise in Heart Disease**—Hoffmann says that the lack of a reliable method for testing the cardiac function should not lead the physician to forbid all exercises in the presence of doubtful signs. It is his aim to demonstrate that after clinical cure has been obtained in heart disease it is not only permissible but advisable to institute gradually increasing exercises. Among 132 patients with cardiac defects he found only ten in whom it was necessary to forbid all sports. All others (122), who no longer had a decompensation and who no longer required treatment, could be permitted to take up some sport under medical supervision. Those whose reaction to exercise was at first unknown were encouraged to swim under the supervision of a physician. In many instances it was acknowledged that swimming is the most favorable physical exercise. This is probably chiefly due to the horizontal position in the water, which facilitates the backflow of the blood from the periphery. Moreover, a suitable respiratory technic probably plays a part. It is important that the patient become accustomed to the water, especially at the onset of the swimming exercises he must be guarded against excessive shock and dyspnea. The clinical histories of three patients are described, two were young persons with mitral defects and one was a man aged 51 with an aortic insufficiency of long standing and with myocardial impairment. It is demonstrated what can be accomplished in sports, in spite of cardiac defects. In order to retain the increased capacity, the exercise must be continued.

 Spontaneous Generalized Osteoporosis in Small Girl J C Schippers—p 108  
 \*Sternal Puncture in Children Normal Sternal Punctate in Children G M H Veeneklaas—p 118

**Sternal Puncture in Children**—Veeneklaas, in exploring the possibilities offered by sternal punctures in children for the examination of the bone marrow, studied the sternal punctates of fifty children. He found that the manubrium, having the largest medullary nucleus, is the best site for the puncture. An exact estimation of the percentages of the different cells is possible only on the basis of statistical formulas. Megaloblasts, the nucleated and youngest red element, with a diameter of from 16 to 18 microns, which are found in large numbers in the bone marrow of patients with pernicious anemia, are found regularly, although in small percentages, in the sternal punctate of children

and must be regarded as normal elements. Micromyeloblasts and paramyeloblasts, which heretofore have generally been regarded as leukemic cells, were likewise regularly observed in small numbers in the medullary specimens of children. Thus they too must be regarded as normal manifestations in children. With increasing age there appears in the bone marrow a change in the ratio of granulocytes to lymphocytes, just as in the case in the blood. Megaloblasts, myeloblasts and lymphoblasts are more numerous in children less than 3 years of age than in older children. In cases of lobar pneumonia a pathologic augmentation of myelocytes and of plasma cells can be observed in the bone marrow. In severe cases of celiac disease the bone marrow is characterized by the occurrence of megakaryocytes that are staff leukocytes and segmented leukocytes with a diameter of from 16 to 18 microns. In severe cases of leukemia the blood picture may be agranulocytic, whereas the bone marrow contains numerous cells of a leukemic nature. Thus, even if the blood picture is normal and there are no noticeable symptoms, puncture of the sternum will permit the diagnosis of leukemia.

 New Case of Myxedema Accompanied by a Reflex of Myotonic Type of Achilles Tendon S Eckerström—p 136

**Bilirubin in Blood Serum and Urine**—According to Snapper and Bendien, many investigations have been made on the physicochemical condition in which bilirubin appears in the body fluids. They cite studies carried out by others and by themselves. Their own method was that of ultrafiltration, whereas others employed cataphoresis and ultracentrifugation. They show that the investigations with the different physicochemical methods make it appear highly probable that the serum bilirubin is bound exclusively and quantitatively to the serum albumin. This is the case with any serum, no matter whether the reaction is direct or indirect. In urine from patients with jaundice and in watery solution bilirubin is present in the crystalloid state. The particles, however, are still coarsely molecular, so that on ultrafiltering these fluids the concentration of the bilirubin in the ultrafiltrate depends on the concentration of the colloidum solutions from which the membranes are prepared.

### Nicotinic Acid in Experimental Gastroprival Pellagra

—Petri and his associates state that previous experimental studies have demonstrated that surgical removal of the stomach in young dogs and pigs gives rise to a severe chronic and fatal pellagra. Moreover, on the basis of various therapeutic experiments on dogs with gastroprival pellagra and on patients with endogenous pellagra the existence of a hitherto not demonstrated antipellagrous function associated with the stomach seems highly probable. Large additions of yeast to the diet given to the dogs made no change in the development or character of the disease, whereas administration of human gastric juice or dried hog stomach brought about a rapid and conspicuous improvement in these animals and also in the pellagrous patients. At present experiments are carried out on gastrectomized pigs in order to determine the influence of parenteral administration of vitamin A, vitamin B<sub>1</sub>, riboflavin and nicotinic acid in the course of the experimental gastroprival pellagra and the associated morphologic changes. A preliminary account of the results obtained by administration of nicotinic acid is given in this report. The experiments, which were carried out on pigs, demonstrated the failure of nicotinic acid to exert an effect on experimental gastroprival pellagra. This is contrary to the effect of nicotinic acid in the pellagrous condition produced in

pigs by feeding experiments. It appears that this effect of nicotinic acid is dependent on the presence of a particular ("anti-pellagrous") function of the stomach. This view seems further to be confirmed by experimental observations obtained by a special technique. Thus the view advanced by Petri and his collaborators as to the gastrogenous character of pellagra has been substantiated further.

**Roentgen Diagnosis of Primary Tumors of Lung**—In this paper on the roentgen diagnosis of pulmonary tumors, Westermarck confines himself to the primary growths of the lung. In so doing he pays especial attention to their early diagnosis. He deals with benign tumors as well as with primary sarcoma of the lung. Considered from the pathologic-anatomic point of view, the benign bronchial tumors can be classified as polyp, fibroma, lipoma, and adenoma. These tumors give rise to bronchostenosis, which condition dominates the roentgenologic aspects. The diagnosis requires bronchography. The author says that many benign pulmonary tumors are congenital. They spread toward the periphery of the lung. The chondromas are the most common. These appear as rounded or somewhat irregular shadows in the lung and they frequently contain calcifications. Besides chondromas, however, other mesenchymal tumors are found in the lung. The literature contains reports about fibromas, myomas and angiomas of the lung. In order to differentiate these tumors from extrapulmonary growths, bronchography should be carried out and diagnostic pneumothorax should be induced. Bronchial cancer in most cases gives rise to bronchostenosis. On the roentgenogram, this stenosis is usually in evidence earlier than is the shadow of the tumor. In order to facilitate an early diagnosis, the changes caused by bronchostenosis should be watched for and bronchography should be carried out. During the early stages the cancer is usually localized in the finer bronchial ramifications and from here it progresses in a central as well as in a peripheral direction. In the final stage either extensive infiltration of an entire pulmonary lobe or metastases in the hilus dominate the picture. Pulmonary sarcomas are comparatively rare. They are characterized by an expansive mode of growth and form large or small rounded homogeneous shadows, which are located in the center of a pulmonary lobe or occupy an entire lobe or most of the lung.

**Roentgen Therapy in Rheumatic Diseases**—This report by Kahlmeter is based on a material of approximately 5,000 cases of different forms of rheumatic disease which were observed during the years 1925 to 1937. Before discussing the results, the author describes the technique which he employed. The tension was 173 kilovolts, the intensity 5 milliamperes, the filter consisted of 0.5 mm of copper and 1 mm of aluminum and the focus-skin distance was 30 cm, except in case of the fields which measured 15 by 20 cm, here it was 40 cm. In most cases the dimensions of the fields were 10 by 15 cm, though fields measuring 8 by 10 cm were also frequently irradiated. At each session from 150 to 200 roentgens was applied and these doses were repeated two or three times at intervals of two or three days. After an interruption of from four to six weeks a second series was applied in the same manner if it proved necessary, perhaps to be followed by a third series after from six to eight weeks. To be sure, the aforementioned doses were not used in all disorders. In conditions like acute bursitis and peritendinitis stronger doses (200 roentgens) were given once or twice, however, in acute gonococcal arthritis from 75 to 100 roentgens was applied three or four times. Summarizing the results obtained with roentgen therapy, the author says that the effects are best in gonorrheal arthritis, gout, acute

infectious arthritis of the septic type and acute cases of bursitis and tendinitis. Although in a lesser degree, results are generally favorable in all forms and stages of tendinitis, in localized myalgia and neuralgia and, on the whole, in all periartritic symptomatic conditions. Thus, in case of hip disease, for instance, it is important to irradiate not only the joint itself but also the attachments of the trochanteric and adductor musculature. Moreover, the beneficial effect obtained in cases of osteo-arthritis of the knee joint is mainly due to the effect on the tendinitis and tendovaginitis which is always present in the surroundings of the knee joint, particularly on the inner side. It is no easy task, however, to analyze the benefit that may be derived from roentgen treatment in chronic polyarthritis ("rheumatoid arthritis"). In general it may be said that the effect is better the more recent the articular symptoms and so far as they are of clearly inflammatory nature or are periarticular and so far as the restricted mobility is due to the painfulness of the periarticular soft tissues and not to cicatrization or exudate or destruction of cartilage.

### Nordisk Medicinsk Tidskrift, Stockholm

16 1973 2012 (Dec 17) 1938

- \*Clinical Aspects of So Called Spontaneous Subarachnoid Hemorrhage E Lyngar —p 1974
- Thrombo-Angitis Obliterans (Buerger's Disease) K K Nygaard —p 1982
- Ten Years Experience with BCG Vaccination in Norrbotten C Nreslund —p 1990
- \*Ovalocytosis N Soderstrom —p 1996

**Spontaneous Subarachnoid Hemorrhage**—Lyngar says that clinically hemorrhage in the subarachnoid space constitutes a relatively well defined picture, since the symptoms depend on the hemorrhage as such without regard to its cause. The word "spontaneous" indicates that the hemorrhage is not due to trauma. Diagnosis is based on the presence of bloody spinal fluid, the blood corpuscles sink without coagulation, and the fluid over the corpuscles is yellowish. The source of the bleeding cannot be definitely determined in life. A bleeding may reach the subarachnoid space secondary to a hemorrhage in the epidural or subdural space or secondary to a superficial intracranial hemorrhage which makes its way either through pia or into the ventricle system, or the bleeding may originate in the blood vessels in the subarachnoid space. The author reports fourteen cases observed during a three year period. Seven patients were under 35, the youngest was 9 months old. Nine recovered. The disorder was characterized by sudden onset and symptoms of gradually increasing intracranial pressure and meningeal irritation. Only two cases were afebrile. Ophthalmoscopic examination, done in thirteen cases, revealed in seven changes in the fundus probably due to the intracranial hemorrhage, namely changes in the optic papilla, retinal hemorrhage, and in one case atrophy of the optic nerve. The etiology was often uncertain. The possibility of angiospastic disorders as an underlying cause is considered. In one case there was epilepsy, in one hypertension with headache, in three there had been headache for a longer time. Treatment consisted of spinal punctures, with removal of never more than from 5 to 8 cc of the cerebrospinal fluid in one session.

**Ovalocytosis**—Ovalocytosis, Soderstrom states, is a morphologic blood anomaly characterized by the more or less marked elliptic form of most of the red blood corpuscles. Reports of more than 100 cases have been published. There was hypochromic anemia in some of the cases, in some a hemolytic jaundice was present. In some of the cases with anemia definite ovalocytosis persisted after disappearance of the anemia, while in others the ovalocytosis was definite only in the anemic stage. Familial occurrence of the ovalocytosis was frequent. The ovalocytes are rather small and deficient in hemoglobin and should not be confused with the elliptic megalocytes of pernicious anemia. In the three personal cases reported the first examination revealed a moderate hypochromic anemia. In one of the cases treatment with iron resulted in parallel regression of both the anemia and the ovalocytosis, in another, which was familial, the treatment was followed by improvement of the anemia but the ovalocytosis remained unchanged. Hematocrit examination, according to Enghoff, showed a low volume index in two cases.

## A Fourth Year Medical Student Is Introduced to Lobar Pneumonia

JOHN F. DOUGHERTY

Boston University School of Medicine Class of 1939

BOSTON

In the year 1867, while discussing medical education, Oliver Wendell Holmes stated

The most essential part of a student's instruction is obtained, as I believe, not in the lecture room but at the bedside, nothing seen there is lost, the rhythms of disease are learned by frequent repetition, its unforeseen occurrences stamp themselves indelibly on the memory. Before the student is aware of what he has acquired he has learned the aspects and causes and probable issue of the disease he has seen with his teacher, and the proper mode of dealing with them, so far as his master knows

The basic truth of this remark has been more and more accepted by teachers of medicine, and now as a result the average present day student in a good medical school is fortunate in the almost unlimited opportunities he is offered to pursue the study of medicine at the bedside in large teaching hospitals. In such hospitals clinical material of all forms is abundant, and newer forms of therapy are constantly being employed, the student is in a position to observe, at first hand, their efficacy or failure

This is particularly true with reference to an important and common disease such as lobar pneumonia. Through didactic teaching, with his attention focused on the textbooks and with only occasional observation clinics, the student is apt to form the idea that lobar pneumonia is, for the most part, a very typical disease, with constant and impressive physical signs. It is only when the occasion for a clinical clerkship is presented and actual cases are placed in his hands for examination and diagnosis that he becomes aware of the frequent and almost diabolic nonconformity of this disease.

In the Fifth Medical Service at the Boston City Hospital, as soon as a patient with lobar pneumonia is admitted he is seen by one of the house officers, who immediately takes a blood culture and sends a sample of the patient's sputum to the Pneumonia Laboratory for typing. The Pneumonia Service, under the leadership of Dr. Maxwell Finland, is notified that a patient with pneumonia has been admitted, and some member or members of this service

review the case and offer therapeutic and prognostic suggestions. In the meantime the patient is placed as soon as possible in the hands of one of the clinical clerks, who are fourth year students. The clerk is made responsible, the condition of the patient permitting, for the following items:

- 1 A complete history, including family, marital, social and past history as well as of the present illness

- 2 A thorough physical examination (Both history and physical examination may be limited in extent if the patient is critically ill but will be completed during convalescence)

- 3 Examination of the blood to include red blood cell count, white blood cell count, hemoglobin determination (Sahli), differential count with a description of the smear, hematocrit study, mean corpuscular volume, mean corpuscular hemoglobin and mean corpuscular hemoglobin determination

- 4 Examination of the urine to determine color, reaction and specific gravity, tests to determine the presence of sugar, albumin, acetone and bile, and a microscopic examination of the centrifuged sediment

- 5 Microscopic examination of the sputum after Ziehl-Neelsen (acid fast), Gram and Löffler's methylene blue staining

- 6 Examination of the specimen of stool for the presence of occult blood

- 7 Withdrawal of blood for Hinton's test and, when the patient is over the age of 50 or when it is otherwise indicated, withdrawal of blood for nonprotein nitrogen or sugar determination

- 8 Any further examination, such as lumbar puncture or gastric analysis, at the discretion of the house officers or visiting staff

On the morning following admission the history, physical examination and results of the laboratory studies are discussed by the clinical clerk with one of the resident staff, and later in the morning the case is presented to a visiting physician, who questions the student concerning his diagnosis and suggested therapy.

During the hospital stay the patient's clinical course is followed by the clerk under the surveillance of the house officers or visiting staff, and the clerk is responsible for the daily laboratory work that is indicated and for progress notes.

Every opportunity is extended to observe the effect of whatever therapy is given, and the clerk also is expected to know the results of any x-ray examination or electrocardiographic or other tests performed.

Should death occur and permission for a post-mortem examination be obtained, the clinical clerk is informed of the time of the necropsy and is given an opportunity to correlate the clinical and the postmortem appearance in the case that he has had under observation in the manner outlined.

For the three months period from September through November 1938, to give an example of the opportunities now offered students in an active teaching service, the clinical clerks in the Fifth Medical Service of the Boston City Hospital had occasion to observe in this manner twenty-three cases of lobar pneumonia. These cases represented an unusually fine cross section of lobar pneumonia. The age of the patients varied from 15 to 76 years, the duration of the symptoms before the patients entered the hospital varied from two to fourteen days, and the physical signs presented by the patients varied from an almost negative examination and history to an overwhelming, prostrating infection.

All these patients had sputums which were typed and found positive for some specific type of pneumococcus, abnormalities of the chest were in all cases confirmed by x-ray examination.

Among the twenty-three cases thus observed there were six deaths, or a mortality rate of 26 per cent. Of these six patients, two were examined post mortem at the Mallory Institute, two were regarded as medicolegal cases because of a history of alcoholism, and permission for postmortem examination on the remaining two was refused. While so many fatal cases in a group so small seems unusually high, these fatalities are partially explained by the fact that in one case (6) not only was there a delay in entering the hospital, the patient having been ill six days before admission, but also there was a long history of chronic alcoholism, in another case (7) there was delay before hospitalization and the clinical picture was complicated by hypertension, obesity and alcoholism. In the other four fatal cases, death appeared to occur as the result of overwhelming infection.

It is noteworthy that of the patients encountered with pneumococcus type II infection, which usually is not considered to be most likely to prove fatal, four died. All received serum. Inquiry shows that approximately the same high mortality rate in the other services of the Boston City Hospital existed for pneumococcus type II infection during the time interval under discussion and that deaths from this type

of pneumonia have been more frequent so far this year throughout the entire state. At first this was thought due, perhaps, to a lowered efficacy of the serum, but after adequate investigation it now appears that in this locale at the present time there is a pneumococcus type II of greatly increased virulence.

An opportunity was afforded to observe closely the typical response in pneumonia to specific serum therapy and to learn the technic of administration. A patient receiving type I serum showed prompt recovery. It is truly impressive to any one to see the marked improvement in the general condition of a patient—disappearance of delirium, drop in temperature, pulse and respiratory rate and decrease in cyanosis—following serum therapy. Such improvement was noted in several cases within a few hours after serum treatment was commenced.

The students are taught the factors that influence the dosage of the type specific serum, namely the age of the patient, the amount of involvement, the presence of a positive blood culture, the duration of the disease, and pregnancy or any other complications.

They are also impressed with the necessity for inquiring about and testing for sensitivity and to be prepared to cope with any of its manifestations during serum treatment. They are shown the results of intracutaneous and conjunctival tests and are instructed to watch for the immediate and the thermal reactions, as well as the symptoms of serum sickness.

One case was encountered (case 12) in which the type specific serum seemed to have no effect on the temperature, pulse or respiratory rate. Another typing was done which disclosed the presence of a second type of infection, and injection of serum specific for the second type of pneumococcus brought about an immediate fall in the temperature, pulse and respiratory rate, and uneventful convalescence proceeded. This case emphasized the vital importance in the treatment of pneumonia of accurate sputum typing.

The utility of sulfanilamide in the treatment of lobar pneumonia, particularly that caused by pneumococcus type III, was witnessed, as well as the use of the newer types of this drug, specifically sulfapyridine.

In view of the statistical inadequacy of this report and with a consciousness of my inexperience, I wish it understood that this article is in no sense an endeavor to discuss the diagnosis or treatment of pneumonia. It is written in a grateful effort to describe the opportunities offered to an ordinary medical student as part of his fourth year work in medicine to become introduced to so important and so common an infectious disease as pneumonia.

# Syphilis as a Problem in American Colleges

R A VONDERLEHR, MD

Assistant Surgeon General, U S Public Health Service  
WASHINGTON, D C

Interest in syphilis as a public health problem has been growing in virtually every quarter during the past few years. Our institutions of higher learning, primarily through groups such as the American Student Health Association and more recently through students, have acknowledged the problem. With a few very noteworthy exceptions, however, the attitude in general has been that, while the college might be interested in the general educational aspects of syphilis as a public health problem, syphilis as a medical problem among students is of negligible importance.

This attitude is not surprising, for relatively little has been known about the extent of the venereal diseases among college students, and until recently such things could hardly be spoken of in public. Fortunately during the past few years this state of affairs has greatly changed, especially in the point of view regarding discussion. Far-sighted physicians at the second National Conference on College Hygiene, of which the American Student Health Association was one of the sponsoring members, pointed out that "every approved means should be utilized in identifying and controlling venereal diseases."

But without facts to demonstrate that diagnosis and control of syphilis among the college population is a sound program from budgetary, medical and educational points of view, opinions persisted that the college student was a "selected" person not to be included in groups with a high prevalence of venereal disease.

## THE RECENT PUBLIC HEALTH SERVICE SURVEY

Some few attempts have been made to determine the extent of syphilis among college students, notably the work of Diehl of the University of Minnesota, but all such work has been limited to single institutions. In order intelligently to consider the problem—if there is one—of syphilis among college students, it was evident that facts should be gathered regarding the extent, nature and results of tests carried on among all American colleges.

This the United States Public Health Service attempted during the past year. A recently published article<sup>1</sup> has brought out a number of illuminating facts that should be of value in determining policies of college health administrators with regard to the venereal diseases. The study is by no means the final word on the

subject of syphilis in colleges but it provides as broad and comprehensive a sampling as has yet been described.

Questionnaires were sent to some 750 representative colleges early last spring. Replies were received from 515 institutions, which represents a rather adequate return of those colleges at least nominally concerned with student health problems. Records of 83,399 blood tests are included in the study. Of these, 5,011 tests were made on students either in colleges for white students only or in colleges with a very small percentage of Negro students.

Of the 78,388 tests given white students, 156 proved to be positive, a prevalence rate of 19.9 to 10,000 students. This verifies previous observations over the past decade.<sup>2</sup> These data have been compared by some investigators to the usual adult prevalence rate of 1 per cent, with the conclusion that syphilis is relatively unimportant in the colleges.

However, the comparison of the college rate with the corresponding age group of the entire population indicates that syphilis is probably as common among college students as among any other large group of comparable age. Since blood tests are usually given to entering students, mostly freshmen, the great majority of individuals studied in this survey fall within the 15 to 19 year age group, with a smaller proportion in higher age groups. A recent estimate<sup>3</sup> of the rate for the general population age 15-19 years is 18 to 10,000. The slightly higher rate for college students when compared to the 15-19 year age group may result from the fact that students in older age groups, such as juniors and seniors, are included.

Consideration of 2,312 tests given in all-Negro institutions showed positive reactions in sixty-two cases, or 268 cases to 10,000 students. This compares with the general Negro rate of about 300 to 10,000<sup>4</sup> in the same age group.

Breakdowns of the data by sex, region and size of school enrolment were made. There is an indicated difference of about 15 per cent less syphilis among college women than among college men. Such a difference is in line with nationwide prevalence rates by sexes. Regional division into East, South, Central and West

2 Diehl H S Wassermann Reactions in College Students Am J Pub Health 21 1131-1135 (Oct) 1931 Venereal Disease Among College Students, Journal Lancet 56 295-299 (June) 1936 Boynton Ruth E and Davies B P The Routine Wassermann Test in College Students Ibid 58 134 (March) 1938 Cole L R Survey of Syphilis Among Students at the University of Wisconsin, Arch Dermat & Syph 38 70 (July) 1938

3 Vonderlehr R A and Usilton Lida J Chance of Acquiring Syphilis and the Frequency of Its Disastrous Outcome Ven Dis Inform 19 396 (Nov) 1938

4 Study by the Division of Venereal Diseases, United States Public Health Service (unpublished data)

Read before the American Student Health Association New York Dec 30, 1938  
1 Tumbleson R C, and Ennes, H W Jr A Study of Syphilis in American Colleges J Social Hyg, January 1939

showed slight variations, but on the basis of the number of students tested there is no indication that any region has a higher rate than another. There is no significant difference, for example, between the rates for comparable groups in New England and the Deep South. Similarly, slight variations between rates for schools with small enrollments as compared with rates for schools with large student bodies are without significance. These facts seem to add evidence to the statement that syphilis recognizes no geographic or social class bounds.

A factor shown by this study to be a measure of adequateness of a college syphilis control program is the testing method used, that is, whether it is routine or selective.

The term "routine" as used in this study is considered as designating tests performed without exception on all students of a given group, usually freshmen and other entering students. Tests given on suspicious clinical signs at the request of the college physician or of the student were arbitrarily grouped together under the term "selective."

#### ROUTINE TESTS

Routine tests were given 42,074 students, of whom eighty-four gave positive reactions—a prevalence rate of twenty cases of syphilis to 10,000 students. Of the 36,314 tests made at the request of the physician or student, seventy-two showed positive reactions—a rate of 19.8 cases to 10,000 students. Consideration of the fact that the rates are practically identical regardless of the method of testing and that the variable factor is the total number of tests given leads to the conclusion that the number of cases found in a given student population is in direct proportion to the total number of students tested.

Thus, testing solely on a selective basis would not be considered an optimal application of the serologic diagnet from an epidemiologic standpoint. This follows from the fact that students selectively tested in all schools, large and small, represented not more than 15 per cent of the total student enrollment of the school, while routine tests were made on virtually 100 per cent of the group under consideration. For example, among 20,000 students, routine testing would be expected to reveal about forty cases of syphilis. Under the selective system 15 per cent, or 3,000 students, would be tested. At the rate of twenty cases in 10,000, only six cases would be expected, while forty actually would exist in the total student population.

Failure to detect the hidden manifestations of syphilis is frequent. Many infected persons do not know that they have syphilis and therefore do not request examination. The consequence is that testing by selective methods frequently results in failure to detect syphilis among college students. Even one case of

syphilis undetected may take on the aspects of a serious control problem. If that one patient spreads the disease to others, it finally becomes the focal point of a small epidemic. Early diagnosis and treatment is therefore the answer not only for protection to the individual but for the entire student body and college community.

Public health authorities agree that control efforts, to be effective, must be focused on individuals in the age groups of most frequent exposure. College students form a potential section of this important group. Control measures applied here offer real hope that the general rate can be materially reduced.

Perhaps the most noteworthy fact of the survey is the indication that college administrative officers are fast approaching this point of view. In large measure they realize that there is necessity for fighting syphilis on every front, including the college campus. More than 40 per cent of the 515 institutions that cooperated in this study already have in operation facilities for testing students. Most of these, of course, are only on a selective basis, but twenty-three schools give tests as a routine to all entering students. In particular in the Negro schools, college administrators have recognized the problem and are taking vigorous steps toward its solution. Of the eleven Negro colleges reporting, nine give tests, of these, six test by the routine method—a very practical example of facing a problem squarely. Throughout the nation a trend toward more attention to this problem is evident. In many cases, programs have been called for by students themselves and their call has been heeded by many college authorities. These are healthy signs.

The facts seem to substantiate the belief that there is a syphilis problem in the colleges. Two questions yet remain. First, is syphilis in colleges predominately a medical or an educational problem? Second, what policies may be followed?

Comments on some questionnaires returned in this study held that even if as many as twenty cases in 10,000 could be shown to exist among the college population, the time and cost of testing the entire student body as a routine would not be worth while.

It must be remembered, however, that syphilis is a dangerous communicable disease, one which, if untreated, results frequently in cardiovascular disease, neurosyphilis and untimely death but which, if found and treated early, has more than an 80 per cent chance of satisfactory outcome.<sup>5</sup> And syphilis is a special problem of youth, with more than half of all cases being acquired before the age of 25 years.

Every state except Wyoming has a public health laboratory which should make serologic

5 In discussing this paper, Dr. Ruth E. Boynton of the University of Minnesota reported that four of the sixteen cases detected by routine serologic tests and under treatment at the Students Health Service showed central nervous system symptoms.

tests available to colleges. By utilizing this source the cost to the college of taking routine tests will be far overbalanced by the social value of discovering and bringing infectious cases under treatment. The survey cites as a typical example of this point of view the statement of one doctor that "the finding of a case of syphilis should be as worth while as the finding of a case of pulmonary tuberculosis." The inclusion of a blood test for syphilis in every routine physical examination, including examinations at matriculation, would be a substantial contribution to the good health of the student population.

#### COLLEGES SHOULD SET THE EXAMPLE

There exists a direct connection between the medical problem in the schools and colleges and in other youth groups. The connecting link is the educational and demonstrative value of college programs.

The actions and thoughts of college administrators and faculty command respect. Thus health programs in our institutions of higher learning which frankly and openly recognize syphilis as a communicable disease problem cannot help but have a salutary effect on public opinion. Colleges and college students "set the style," so to speak, in a number of respects. The college student is a member of an important social group. His actions are watched with keen interest by a large part of the populace. Widespread knowledge that college students are being systematically tested for syphilis as a routine part of their health examinations and that both faculty and student consider it as any other communicable disease will present a practical example of what should be done, in addition to delivering more blows at the old prudish state of mind.

The effect on college students of having this problem pointed out to them, of being given an opportunity to discuss it and its related problems and of seeing practical, diagnostic and control measures actually applied cannot be overemphasized. The college student is the leading citizen of tomorrow. Today most of the important posts are held by college men and women. So it is that the degree of understanding of health problems which the college student acquires will condition to a substantial extent his thinking on problems of community and public health in the future.

It is significant that the American Youth Commission of the American Council on Education in a study<sup>6</sup> about to be published says of the college student "As a member of a special group in which society has invested heavily, he should become a leader of thought in those concepts by which family and community health may be preserved."

It has been pointed out more than once after detailed and exhaustive investigations that our schools and colleges are not properly preparing students to live a healthy life. Only recently the magnitude of the problem was recognized by a large group of health and educational organizations which met to consider means of action. No one will claim that matters of sex education, of the venereal diseases and of preparation for marriage and parenthood have been more than touched on. In too many of these subjects there exists a yawning chasm in curriculums.

For at least one of these subjects the reasons militating against a frontal attack have been largely removed. Syphilis is now known to be a problem in the colleges. We know we can control it by applying modern public health principles. We know that, if we do, public opinion will support that action. And we must realize that colleges have a responsibility to take the lead in the field of health education. Certainly until colleges recognize subjects such as syphilis and other venereal diseases to be valid topics of instruction, little advance can be hoped for in secondary schools.

Instruction in the venereal diseases should be included in the usual course on the control of the communicable diseases. It should also have a proper place in any course dealing with sex education, hygiene and public health. Syphilis may well be used to illustrate a modern community health program with emphasis on health education.

Another phase of the educational program is coordination directly with student activities. Syphilis has dramatic interest which has not failed to arouse the imagination of many college students. During the past year and a half a number of effective and highly worth while campaigns have been undertaken by college students. As heads of school health services, college physicians have an opportunity to take advantage of such interest through the medium of student organizations and newspapers to a degree which is rarely possible in other young groups.

Frankly, during the past few months I have been much encouraged by the active interest in problems of health which has been demonstrated by young people. It gives me hope that the people on whom we must lean in the future are awake to problems of correct living. Students are beginning to realize that good health means essentially keeping well, not getting well. If we fail to encourage this concept, with its related implications, we have failed in a major responsibility.

#### THE PLAN FOR ACTION

Since there is a problem of syphilis control in the colleges, what can be done about it? I shall briefly review the alternatives.

<sup>6</sup> Diehl, H. S. and Shepard, C. E. The Health of College Students. Preliminary Report to the American Youth Commission of the American Council on Education, Washington, D. C. May 1938.

As physicians we are aware of the efficacy of modern methods for the diagnosis and treatment of syphilis. Inclusion of a reliable system of finding syphilis quickly, easily and cheaply among a large student population is one of our major concerns. Fortunately the serologic dragnet answers that question. Its application requires little or no addition to the personnel required for the conduct of complete physical examinations on entering students. Cooperation with state or municipal laboratories in most instances will reduce laboratory costs to a negligible figure.

There are three points that should be stressed in handling positive cases. Obviously it is of extreme importance to be sure that the positive report is indicative of syphilis. Competent laboratories usually run several tests on blood specimens, but even their positive reports should be verified by physical examination and a second positive blood test in patients with latent syphilis.

Second, it is very important that the college physician see to it that treatment is begun and carried through. By whom the treatment is to be given is a matter for individual decision. In many cases it may be possible for the student to take treatments from his own physician and pay for them himself. If he cannot, however, the school must see that treatment from some source is forthcoming.

Closely linked to this problem of treatment is a third point. Positive reactions must not be allowed to be the basis of expulsion or other disciplinary action unless the patient refuses to carry through adequate treatment or persists in activity conducive to the spread of the disease. This was emphasized by the second National Conference on College Hygiene.

Syphilis in the college student is a challenge directed particularly to health administrators and educational leaders. Our nation will always face crises as great as or greater than any we have known in the past. It cannot afford to be burdened with men and women unfit to be leaders because of preventable disease.

#### CONCLUSIONS

1 Based on a sample of 78,388 tests, the prevalence of syphilis among white college students is 199 in 10,000. This figure compares closely with that of the corresponding age group in the general population.

2 In colleges for Negro students only the rate was 268 in 10,000 students. This rate likewise is comparable to that for the general Negro population of a corresponding age group.

3 The slightly lower rate among college women is also in line with the national figures.

4 Application of serologic tests on a selective basis results in failure to detect a large proportion of the infected student population. Routine testing of all students is definitely indicated.

5 The cooperation of state and municipal health departments should be sought in performing serologic tests without charge on specimens from college students. This arrangement will lower the cost of routine tests.

6 Routine serologic testing in colleges gives each student a definite lesson in syphilis control and serves to impress the importance of this phase of public health work on him in later life.

7 The action of college authorities in requiring routine serologic tests for syphilis among all students not only would be a substantial contribution to the health of the student population but would set an example which less fortunate young people might be more apt to follow.

## Comments and Reviews

### CLINICAL INVESTIGATION

*Abridgment of an address by Dr. George R. Minot, professor of medicine, Harvard University Medical School, Boston, presented at the dedication exercises of the Squibb Institute for Medical Research, New Brunswick, N. J., Oct. 11, 1938, and published in Science, Nov. 4, 1938.*

Every patient who consults a doctor presents a problem for investigation before the best advice can be offered. Nowhere does a patient stand so good a chance as in a clinic where his disease is arousing scientific curiosity. Every practitioner, at the bedside, must constantly sharpen his powers of observation and judgment, and recognize that his education must be continued by his own strenuous mental effort. His curiosity to learn must never wane. Since medicine deals so essentially with human prob-

lems, the physician must constantly strive to broaden his outlook on life. This may be done by cultivating interests that often would be considered far removed from the practice of medicine.

There is no sharp line of demarcation between the practicing physician and the physician who makes it one of his duties to conduct clinical investigation. Indeed, the clinical investigator must be an able clinician, one who understands human beings and can act wisely for all aspects of a given individual. His training in investigative principles must be sound and he should have an ardent desire to seek for knowledge by scientific methods.

Clinical investigation may be undertaken wherever the physician has his headquarters if he trains himself to keep in mind the study of

problems, however, the establishment of appropriate space and opportunities for clinical investigation in large hospitals where the study of patients under controlled conditions can be undertaken seems especially wise. This permits investigators to be surrounded with a wealth of clinical material for study from which ideas can originate and allows the hospital to be a progressive modern institution and the patients to receive the very best treatment. It is of great advantage if the clinical investigator is in close contact with men working in a wide variety of scientific fields and especially in those disciplines closely related to clinical medicine, such as pharmacology, bacteriology, chemistry and biology. Mingling of such men offers opportunity for the free exchange of thought, indeed, this arrangement allows the ideas originating from the needs of the patient to be readily carried for elucidation to some laboratory of fundamental science, and knowledge obtained there to be applied in the clinic. For the cure and prevention of disease and the relief of pain the final test is on man himself, so that a clinical investigative unit needs to be a part of an institute for medical research or associated with one.

#### GREAT LABORATORIES UNNECESSARY

Clinical investigation does not necessarily require great laboratory set-ups. The patient is the center of the picture, wards are the salient feature of the clinical investigative unit. The technical apparatus required for intelligent observation and for the proper care of the patient is but a means to an end and is a relatively insignificant, though often to the casual observer the most impressive, feature of a clinical investigative unit. The most important possession, besides the sick people, is the recorded data collected with a view to obtaining a definite pattern and frequently ascertained by simple procedures, often entirely by the use of the intellect. From the trustworthy records of natural phenomena and of the actions of organisms under controlled experimental conditions, concepts concerning disease are formulated leading to the alleviation of man's ailments. The plodding worker often obtains a long record and masses of data which are sometimes thought to indicate good work. That is often far from the case, because his data may have been obtained without critical understanding. Quantity does not supplant quality. The individual with an aggressive mind can often by skilfully planned questions and observations in relatively small quantity elicit more significant information than is found in some voluminous records. The foundation of research work lies in the quality of the minds of the investigators and the freedom and tranquillity permitted for the use of their abilities. Free choice of problems and free choice to follow

leads disclosed must be the privilege of the experienced investigator.

Although any physician may conduct clinical investigation and share his knowledge with his colleagues, the term clinical investigator is usually applied to a man who devotes a considerable amount of time to the study of clinical problems in organized clinical laboratories. Many men, who essentially never observe a patient, study numerous problems pertaining to the clinic, but such individuals are not clinical investigators.

A trained clinical investigator may approach problems in two different ways. In the first instance a clinician seeks tools through which to solve problems that originate in his mind at the bedside, such a man appreciates, for example, that, to supply the deficiency of the blood-clotting mechanism in hemophilia, chemical procedures should be utilized to discover something that might permanently alleviate the disease if given by injection each day. The second method of approach also is for a man with clinical training, but one who has acquired the use of tools, which he takes to the bedside to apply to problems suggested by the tools, for example, a man trained in the chemico-physical aspects of the clotting of blood, who seeks a patient to elucidate the mechanism of blood coagulation. The former is more truly the clinical investigator, and it is by the intellectual rather than by the technical method that he approaches problems. This does not imply that it is unwise for investigations of fundamental importance to proceed from morphologic, chemical or physiologic motivations without reference to the immediate needs of the clinic, for it is by the study of fundamental problems that most significant advances are made. Both types of clinical investigators have their place in the development of useful knowledge, but if aggregations of individuals, chosen only because they are acquainted with special technics, form the personnel of a clinical investigative unit the practical needs of clinical medicine are apt to be forgotten.

It is certainly an incorrect conception of research that it makes a man heartless or indifferent to human suffering. Many clinicians who have spent much time in investigation are unusually keen in their ability to appreciate and to treat the emotional disturbances of patients. In fact the clinical investigator is apt to be successful somewhat in proportion to his appreciation of the sick man as an individual. He must have the power to see straight, which is a rare gift. To see no more and no less than is actually before one, to see with one's reason as well as with one's perceptions—that is to be an observer and to read the book of nature aright. To note the resemblances of things one

to another may be an essential point in acquiring information. Factors often need study one at a time, yet it must not be forgotten that synthesis is essential in the formulation of final knowledge. The investigator must ponder on topics where emotions blend with cold reason and where the answer is dictated by the emotions, though it is largely formed by reason. Emotion is the driving force that arouses inquisitiveness, sustains interest and keeps the investigator at work through drudgery. Reason is the critical control that guides and checks progress. It is developed by long training in the scientific method. Emotion and reason are always mixed, one can only do one's best to use each for its serviceable purpose and avoid the usual mistake of allowing emotions to dominate one's judgment.

Whether a man is to undertake clinical investigative work does not depend on his precise occupation but lies in the man himself. Whoever undertakes clinical investigation must learn to recognize clinical facts, realize that intuition often guides, and that the patient's health must never be jeopardized. He must establish a detailed diagnosis without pothering over unessential details and proceed to action for every aspect of the patient and his case. This type of work has great educational value. Every physician must be trained to look at problems from more than one angle and be unwilling to confine himself to standardized procedures. By making frequent contacts with those especially studying medical problems, he will constantly imbibe knowledge. An understanding of the principles of scientific investigation aids him to judge critically, to appreciate the nature and significance of proper controls, and to evaluate the significance of the many communications published on medical topics.

Before a problem is intensively studied it is essential to become acquainted with previously acquired knowledge on the subject. Although subservience to the past makes stagnation, development of it is true progress. Science may render that which went before obsolete, but it builds on the past, constantly advancing new knowledge from the standpoint of the already known. Thus the investigator must consult authorities in large part by going to the library. Consulting colleagues is extremely helpful but does not alone take the place of reading what has been written on a subject. Conversation alone as the only basis for obtaining information can lead to confusion between "authority and the oracle," which is perilous to scientific work. A library is not merely a hall of books but a hall of records of human experience and thought, where one may learn the path along which man has toiled and may discover guiding and liberating influences for the future.

In clinical investigation the studies are often of a collective nature, as in the evaluation of clinical data or of new procedures, or in the correlations of chemical and pathologic information. Proper statistical methods must be employed and standard deviations and probable errors calculated. The descriptive discipline of nosography—the painting of accurate pictures of disease—is a useful guide to keep experimental procedures from going astray. This type of work may depend on the good fortune of observing several cases and not on planned investigation. There is need for more accurate work of this sort especially concerning initial symptoms and the natural history of long-lasting chronic conditions. Controlled observations of human pathologic physiology is the nature of many of the studies of the clinical investigator. The question of the origin or cause of disease is of unusual importance to study. Therapeutics, which is linked with pharmacology, is essentially experimental and will always have experimentation on man for its chief basis. The action of drugs always needs evaluation. The object, however, is to study the human body and not drugs per se.

#### CONTROL OF CONDITIONS

The control of experimental conditions in human beings is crude as compared with the utmost rigidity in the control of the worker in pure science, so that data of observations may be only qualitative or but crudely quantitative. One of the many variable factors depends on the fact that the human being has a soul and a highly organized nervous system. His emotional reactions, worries, jealousies and the like and his reactions to one or more persons not only can lead to illness but can affect the functions of organs. The medical-social, psychology, economic and allied aspects of individuals can be investigated with profit. The field is a difficult one for reliable scientific study because it involves all the complexities of human life. Even so, a considerable fraction of the successful care and treatment of patients and the prevention of much illness is to be identified with the proper consideration of their medical-social problems. It is significant to realize that a prepared mind, well planned scientific observations and the taking of infinite pains will lead to success. Important original contributions often are made which require only simple technic and clinical wisdom.

The clinical investigator is not to be thought of as a lone worker or as a man sharply separated from other types of doctors. A close relationship with practitioners, specialists and laboratory investigators of many types is mutually beneficial. There are no sharp lines of demarcation between one medical interest and another or between medicine and a variety of disciplines. Cross fertilization at the border-

lines of knowledge can serve to develop new information. The advancement of learning cannot be made in water-tight compartments.

More fundamental than the actual discoveries being made today is the preservation of the right to engage in research. Security and happiness

have profound beneficial effects on the character of intellectual work. As time passes by we must always be alert to adapt ourselves to changes and realize that to understand the present we must look both toward the past and toward the future.

## Medical College News

*Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section*

### Positions in California for Student Intern and Senior Intern

The Personnel Board of the State of California desires to obtain the best qualified persons for student intern and senior intern to fill anticipated vacancies at the state institutions. Written examinations will not be required of applicants, rating being based on education, experience and fitness based on investigation and appraisal of scholastic records. The entrance requirements for the senior intern position is successful completion of the academic course of an approved medical school, including or supplemented by a one year internship, and for the student intern, successful completion of a four year academic course in an approved medical school or registration and attendance in the final year of such course. The senior will assist, under the supervision of a staff physician, with the medical work in a state institution for the mentally diseased or deficient. The entrance salary is \$50 a month and maintenance for self and family, while those maintaining an efficiency rating of at least 80 per cent may receive annual salary increases of \$10 until a maximum of \$90 a month is reached. The entrance salary for the student intern position is \$25 a month and maintenance, while those maintaining an efficiency rating of at least 80 per cent may receive annual salary increases of \$5 until a maximum of \$45 is reached. Applications may be filed at any time during 1939. If a candidate is found acceptable his name will be placed on the list eligible for employment, in accordance with his rating. Applications must be made on official application blanks, which may be obtained from the State Personnel Board at 1025 P Street, Sacramento, 108 State Building, San Francisco, 401 State Building, Los Angeles, or at the Civil Service Commission, Library Annex, Ninth and E streets, San Diego. All applicants must be citizens of the United States.

### Denver Student Wins Harvard Prize

The Henry A. Christian Prize at Harvard University Medical School, Boston, has been awarded to Henry Swann II of Denver, a fourth year medical student. Mr. Swann graduated from Williams College in 1935. The prize, named in honor of Dr. Henry A. Christian, Hersey Professor of Theory and Practice of Physics, is awarded to "the student in the four year class who has displayed diligence and notable scholarship and offers promise for the future."

### Interns and Residents Eligible for Prize

The American Association of Obstetricians, Gynecologists and Abdominal Surgeons has announced that the annual Foundation Prize for this year will be \$100. Those eligible include (1) interns, residents or graduate students in obstetrics, gynecology and abdominal surgery and (2) physicians (M.D. degree) who are actually practicing or teaching obstetrics,

gynecology or abdominal surgery. Competing manuscripts must (1) be presented in triplicate under a nom-de-plume to the secretary of the association before June 1, (2) be limited to 5,000 words and such illustrations as are necessary for a clear exposition of the thesis, and (3) be typewritten (double spaced) on one side of the sheet, with ample margins. The successful thesis must be presented at the next annual (September) meeting of the association, without expense to the association and in conformity with its regulations. For details address Dr. James R. Bloss, secretary, 418 Eleventh Street, Huntington, W. Va.

### Annual Lecture in Honor of Dr. Irons

The Kappa Chapter of the Nu Sigma Nu fraternity at Rush Medical College and at the University of Chicago have established an annual lectureship in honor of Dr. Ernest E. Irons. The first lecture was given March 8 at Billings Hospital by Dr. Evarts A. Graham of Barnes Hospital, St. Louis, on "Bronchogenic Carcinoma." Dr. Irons is clinical professor of medicine at Rush Medical College, from which school he graduated in 1903. He was the dean of Rush for many years.

### Special Lectures at Duke University

A symposium on pneumonia was held at Duke Hospital, Durham, N. C., to which members of the medical profession and technicians were invited. Dr. Frederic M. Hanes, professor of medicine, Duke University School of Medicine, lectured on "Pneumonia in Adults" and Dr. Angus M. McBryde, assistant professor of pediatrics, on "Pneumonia in Infants and Children." Dr. Joseph Stokes Jr., associate professor of pediatrics, University of Pennsylvania School of Medicine, Philadelphia, lectured to the staff and students on "Viruses" February 8, and Dr. Arthur Bruce Gill, professor of orthopedic surgery, University of Pennsylvania School of Medicine, on "Open Reduction of Congenital Hip" February 14.

### Outstanding Graduates of Temple University

The General Alumni Association of Temple University, Philadelphia, announced February 12 the names of ten outstanding graduates selected for conspicuous service to the university and its alumni association. Several different departments of the university are represented in this list, and Dr. James Marsh Alesbury, class of 1922, was the only selection this year representing the school of medicine. These certificates of award were presented at a founder's day dinner at the Bellevue Stratford Hotel, February 15. Leon A. Halpern, D.D.S., president of the General Alumni Association, making the presentations. The speakers were U. S. Senator James J. Davis, Federal Judge George A. Welsh and Dr. William T. Ellis, traveler and author.

## Castellani Lectures at Yale

Sir Aldo Castellani, visiting professor of preventive medicine and public health in the Louisiana State University Medical Center, New Orleans, lectured at Yale University School of Medicine, New Haven, Conn., February 28, on "Medical Organization in Tropical Expeditions" and "Mycetes and Mycoses."

## Intern Alumni Association Winter Clinic

The annual intern alumni association winter clinic at Providence Hospital, Detroit, was held Dec. 28-30, 1938. The guest lecturer was Dr. Walter Schiller, director of laboratories, Cook County Hospital, Chicago, and formerly of the University of Vienna. Among the subjects discussed were gynecology, physiology, pathology and endocrinology.

## Indiana to Publish New Bulletin

The Indiana University School of Medicine, Indianapolis, published the first issue of its new *Quarterly Bulletin* under the editorship of Dr. Jacob K. Berman, assistant professor of surgery. It will publish proceedings of the medical center's weekly conferences, of the monthly meetings of the various departments, of the Medical Advisory Council, papers on medical pedagogy, reports of research and items of general interest. In addition to Dr. Berman and Dean Willis D. Gatch, the editorial board consists of the following: Drs. Ernest Rupel, Robert L. Glass, Edgar F. Kiser, Harold M. Trusler and Frederic W. Taylor, and James F. Glore, medical artist.

## Central Teaching Clinic

The Intern Committee of the Des Moines Academy of Medicine and Polk County Medical Society has established a central teaching clinic which meets at Broadlawn Hospital, Des Moines, Friday mornings as a special feature in the interests of interns and practitioners. The February 3 instructor was Dr. Walter L. Bierring, and his subject, "Relation of Modern Public Health Service to Medical Practice"; February 10, Bernard C. Barnes, "Appendicitis"; February 17, Harry C. Willett, "Treatment of Syphilis"; and February 24, Verl A. Ruth, "Dislocations of the Lower Spine."

## National Board Questions in Medicine

Following are the questions used by the National Board of Medical Examiners in medicine in part two of the examination held Sept. 12-14, 1938.

Answer questions 1 and 2 and three of the remaining four.  
1. What involvement of the nervous system is most commonly associated with pernicious anemia? What are the signs, symptoms and differential diagnostic features? 2. Contrast the physical signs of pneumothorax with those of massive collapse of the lung. 3. What are the signs and symptoms of acute morphine poisoning? Outline the treatment. 4. Discuss the etiology and describe the course of agranulocytopenia. 5. Discuss the etiology and diagnosis of abscess of the liver. 6. What is the significance of albuminuria?

## Michigan Personals

Dr. George Adelbert Richardson has been appointed a fellow in otolaryngology at the University Hospital, Ann Arbor. Dr. Richardson graduated from Northwestern University Medical School, Chicago, in 1938. He has just completed his internship in the Evanston Hospital, Evanston, Ill.—Dr. Fred V. Rockwell, resident in neurology at the University Hospital, left January 1 to be assistant resident in psychiatry at the Payne Whitney Psychiatric Clinic, New York Hospital, New York. Dr. Wilford A. Risteen has been promoted to the position of resident, the assistant

resident in neurology for the first six months of 1939 will be Dr. Leon Ferber, a graduate of the University of Tennessee College of Medicine, Memphis, in 1937. Dr. Ferber just completed an internship in the John Gaston Hospital of Memphis.—Dr. Robert Roy Rabalais, assistant resident in surgery at the University Hospital, has accepted a post as resident at the American Hospital at Neuilly, Paris, France.—Following a year at the University of Oxford on a Guggenheim fellowship, Dr. Lawrence Olin Brockway has been appointed assistant professor of chemistry at the University of Michigan.

## Prize to First Year Medical Student

Beta Tau Mu, honorary premedical fraternity at Louisiana State University in Baton Rouge, offers a prize to the first year student in the school of medicine who took his premedical work at Baton Rouge and who made the highest grades in the first semester. The award is given in memory of Emile Jacob, who would have been a member of the 1942 class of medicine but who died last summer. This prize was awarded at a meeting February 28 to Dionisus V. Cacioppo.

## New York Personals

Dr. Georg Strassmann, formerly professor extra ordinarius for forensic and social medicine at the University of Breslau, Germany, has been appointed to the department of forensic medicine at the New York University College of Medicine, New York City.—Leonard J. Piccoli, Ph.D., professor of materia medica and physiology at Fordham College of Pharmacy, has been elected the first president of the American Association for the Advancement of Professional Pharmacy.—The following promotions have been announced at the New York Medical College and Flower Hospital: Dr. Loudon Corsan Reid has been promoted to the position of assistant professor of pathology, in charge of surgical pathology. Dr. David McCullagh Mayer has been promoted to the position of assistant professor of oral and plastic surgery, and chief of that service.

## California's Seventy-First Anniversary

During the celebration of the seventy-first charter anniversary of the University of California, the medical school held alumni day clinics, March 22, including operative clinics by Dr. Howard C. Naffziger and the surgical staff, and by Dr. Frank W. Lynch and members of his staff in the department of obstetrics and gynecology. In the afternoon, senior students acted as guides to visitors on a tour of the medical center. There were demonstrations under the direction of Dr. William J. Kerr, professor of medicine, and Dr. Francis S. Smyth, professor of pediatrics.

## New Courses in Orientation to Practice

The University of Minnesota School of Medicine, Minneapolis, is offering this spring to senior medical students for the first time a course known as orientation to practice. The series of lectures, beginning April 7 and closing June 16, include the ethics of the practice of medicine, opportunities in and preparation for practice, management of public and private patients, starting the practice of medicine, malpractice, the physician in court, medical care of the indigent and low income groups, medical organization, and quackery, fads, cults and "patent medicines." The lecturers are H. S. Diehl, A. W. Adson, S. M. White, O. J. Hagen, W. A. O'Brien, Ray Scallen, R. E. Scammon, C. B. Wright and Judge Paul Carroll.

### Ludvig Hektoen Lecture

Dr Eleonors T Bell, professor of pathology, University of Minnesota Medical School, Minneapolis, presented the fifteenth Ludvig Hektoen Lecture of the Frank Billings Foundation at the Palmer House, Chicago, February 24, on "The Pathogenesis of Glomerulonephritis Including Lipoid Nephrosis"

### New Teachers at South Carolina

Among the new members of the faculty of the Medical College of the State of South Carolina, Charleston, 1938-1939, are the following

Dr Seaton Saller, department of pathology  
Dr Marcus Edward Cox, department of pathology  
Dr James Marshall McFadden Jr, department of pathology  
Dr Solomon Carl Werch, department of pharmacology and materia medica

### Course on Medical Writing and Use of the Library

The dean of the School of Medicine of Louisiana State University, New Orleans, has announced for the first time a series of lectures on medical writing and the use of the library for first year students. The course begins with an analysis of study habits. A later lecture deals with the principles of medical nomenclature, with special reference to etymology and correct usage. The opening lecture of the second group concerns the historical development of medical libraries. Other lectures deal with the use of indexes, the selection of references and the most important periodic literature. Practical instruction is given in the library, where the students, in small groups, are shown the location of indexes, journals, textbooks and systems

### Massachusetts Personals

The faculty of medicine of Madrid University recently granted the degree of Doctor Honoris Causa to Dr Walter B Cannon of Harvard University Medical School, Boston, and president-elect of the American Association for the Advancement of Science. Dr Cannon is co-chairman of the Medical Bureau and North American Committee to Aid Spanish Democracy. —Dr John C Whitehorn, director of laboratories at McLean Hospital, Belmont, has been appointed professor of psychiatry in the Washington University School of Medicine, St Louis. —Benjamin Kropp, Ph D, has resigned as instructor in anatomy and research fellow in obstetrics at the Harvard Medical School to become lecturer in embryology at Queens University Medical School, Kingston, Ont. —Dr Elliott C Cutler, Moseley professor of surgery at Harvard University and chief surgeon at the Peter Bent Brigham Hospital, Boston, was awarded an honorary doctorate by the University of Strasbourg, France, Nov 22, 1938

### Dormitory Named in Honor of Victor C Vaughan

At the University of Michigan Medical School, Ann Arbor, a new dormitory for medical students is being erected and will be designated the Victor C Vaughan House, in honor of the late Dr Vaughan, who was dean of the medical school from 1891 to 1921

### Assistant Dean Appointed

Dr Franklin E Walton was appointed assistant dean of the Washington University School of Medicine, St Louis, January 28. Dr Walton was graduated from Washington University School of Medicine in 1927, served on the resident surgical staff of Barnes Hospital for three years and was resident surgeon for

two years. He was appointed an assistant in surgery on the staff of the medical school in 1928 and was made an instructor in 1937. Dr Walton will work with undergraduate medical students and act as adviser to students seeking internships after graduation

### Canada Personals

Prof Guy F Marrian, D Sc, of the University of Toronto, has been appointed to the chair of chemistry in relation to medicine at the University of Glasgow, to succeed Professor George Barger, who now holds the chair of chemistry. —Dr William Boyd, professor of pathology and bacteriology in the University of Toronto Faculty of Medicine, gave a Mayo Foundation lecture Dec 1, 1938, at Rochester, Minn., on "Some Reasons for the Recent Increase in Bronchial Carcinoma"

### Pennsylvania State Board Questions

The following list of questions in medicine and surgery were submitted by the Pennsylvania State Board of Medical Education and Licensure at the examination in Harrisburg, January 4

#### DIAGNOSIS, SYMPTOMATOLOGY, MEDICAL JURISPRUDENCE AND TOXICOLOGY

- 1 What symptoms would lead you to suspect the presence of Addison's disease
- 2 Describe the symptoms and outline the diagnosis of acute lobar pneumonia
- 3 Discuss the diagnostic significance of vomiting and name some of the diseases outside the gastrointestinal tract in which this symptom is observed
- 4 What are the criteria for the diagnosis of progressive pernicious anemia? Give the laboratory findings
- 5 What are the symptoms of diabetic acidosis?
- 6 What are the symptoms of vitamin B deficiency?
- 7 In the case of a patient suffering from typhoid fever what are the symptoms of perforation of an intestinal ulcer?
- 8 Describe the signs and symptoms and outline the diagnosis of acute leukemia
- 9 In the event that a therapeutic abortion is indicated what precautions must you take to keep within the law and protect yourself from prosecution in performing the same?
- 10 What are the symptoms of phosphorus poisoning?

### Professor Appointed

Dr Donald Ewen Cameron, recently senior research psychiatrist at Worcester State Hospital, Worcester, Mass., has been appointed professor of neurology and psychiatry at Albany Medical College, Albany, N Y

### Pennsylvania Provost Retires

Announcement of the retirement of Josiah H Penniman, L H D, provost and John Welsh centennial professor of history and English of the University of Pennsylvania, Philadelphia, was made by Thomas S Gates, LL D, president of the university. Beginning June 30, Dr Penniman will hold the title of provost emeritus and will be succeeded as provost by George William McClelland, Ph D, vice president of the university in charge of undergraduate schools and professor of English

### New Nursing Courses at Temple

The School of Nursing of Temple University, Philadelphia, has announced a three year course leading to a diploma in nursing, a combined university and professional training covering five years leading to bachelor of science in nursing and a program for graduate nurses who desire to prepare for supervisory, teaching and administrative positions in nursing schools. The dean of the School of Nursing is Miss Beatrice E Ritter

### Appointments at Harvard

Harvard University has announced the following appointments to the teaching and research staff of Harvard Medical School for the current academic year

Lucie Adelsberger of Berlin, Germany, instructor in bacteriology M D Friedrich-Alexanders-University, Erlangen 1923

Georg Schlomer of Berlin, Germany, instructor in psychiatry, M D Munich 1910

Charles R Atwell, Boston, instructor in psychology, A M Harvard 1931

George M Wyatt, Wilmore, Ky instructor in roentgenology, M D Western Reserve, 1923

Rupert A Chittick, Belmont, Mass, assistant in psychiatry, M D Harvard 1929

Thomas Colver, London research fellow in medicine, M R C P London, 1935

Kenneth M A Perry London, research fellow in medicine, M R C P London, 1937

Rulon W Rawson, Chicago research fellow in medicine and assistant physician to the Collis P Huntington Memorial Hospital, M D Northwestern 1938

#### From Oct 1, 1938, to July 1, 1939

Francis R Dieumalde, of Peiping Union Medical College China research associate in biologic chemistry M D Johns Hopkins 1920

#### From Nov 1, 1938, to Sept 1, 1939

Thomas R C Fraser as research fellow in medicine, D P M London '37

Alfredo Lanari, Buenos Aires as research fellow in physiology, M D Buenos Aires '34

Eric K Cruickshank Aberdeen Scotland as research fellow in surgery, M B, Ch B Aberdeen University '37

Maximilian G Verlot, Ghent, Belgium as research fellow in surgery M D Ghent '35

#### From Jan 1 to Sept 1, 1939

Adolph Melzer, Boston, as assistant in surgery M D Cornell '34

Maurice H Greenhill, Worcester Mass, as research fellow in psychiatry, M D University of Chicago '36

School of Public Health, From Nov 1, 1938 to Sept 1, 1939

Nathan Gorin, Boston as assistant in child hygiene M D Boston University '17

### Memorial Scholarships at North Carolina

A fund of \$20,400 has been established at the University of North Carolina by an unannounced donor to provide four scholarships in memory of the late Dr Mark R Braswell, Rocky Mount Dr Braswell graduated from the University of Maryland in 1886 and practiced medicine in Rocky Mount until 1911, when he retired to devote his time to farming and other interests He died in 1937

### Tennessee Personal

Dr Fred L Moore, Bristol, health officer of Sullivan County for the past ten years, has been appointed associate professor of preventive medicine at Long Island College of Medicine, Brooklyn Dr Moore is a graduate of Dalhousie University Faculty of Medicine, Halifax, N S, class of 1924 Dr J W Erwin, Nashville, health officer of Washington County, has been appointed to succeed Dr Moore

### Eastman Memorial Lecture at Rochester

Dr George L Streeter, director, department of embryology, Carnegie Institution of Washington, Baltimore, delivered the Eastman Memorial Lecture at the University of Rochester (N Y) School of Medicine, February 10 His subject was "The Rise of the Three-Germ-Layer Theory in Embryology and Some of Its Limitations"

### Founder's Day at Woman's College

A three day program of discussion on "Current Medical Problems Confronting the General Practitioner" marked the observance of the eighty-ninth anniversary of the founding of the Woman's Medical College of Pennsylvania March 9-11 Subjects listed on the program were "Sulfanilamide and Its Clinical Value," "Barbiturates and Sedatives," "Responsibility

of the General Practitioner in Cancer of the Cervix, Rectum and Breast," "Current Views on the Management of Diabetes" and "Every day Problems in Allergy," discussed by members of the faculty and staff At a founder's day luncheon March 11, alumnae were the guests of the college

### Oklahoma Personal

Donald B McMullen, D Sc, formerly of Monmouth College, Monmouth, Ill, was recently appointed assistant professor of bacteriology at the University of Oklahoma School of Medicine, Oklahoma City, instead of professor of bacteriology, as stated in THE JOURNAL Oct 29, 1938, page 1716

### Alabama Personal

Dr James S McLester, Birmingham, was the guest speaker at the annual convolve of Pre-Medics at the University of Alabama chapter of Alpha Epsilon Delta, February 3 His topic was "Personal Observation of the Practice of Medicine in Europe and Russia"

### Tuberculin, Wassermann and Malaria Tests Offered to Students

Alpha Epsilon Delta, honorary premedical fraternity, recently sponsored a program offering tuberculin tests to the entire student body and Wassermann and malaria tests to new students at Millsaps College Dr John W Dugger, Jackson, Miss, director of industrial hygiene for Mississippi, gave a talk on "Tuberculosis, Its Causes, Importance and Methods of Controlling It" Dr Dolph V Galloway, Meridian, supervisor of syphilis control for Mississippi, gave a talk of corresponding nature with regard to syphilis

### Ohio State Board Questions in Chemistry

The following questions were used by the State Medical Board of Ohio in the examinations for licensure Dec 7-9, 1938, at Columbus

- 1 Discuss the chemistry of bone What factors influence its calcification?
- 2 State the general properties and mention the compound elements of protein
- 3 Give detail of testing suspected stains for blood Explain the chemistry of any reaction used
- 4 (a) What is normal  $pH$  in urine compatible with health?  
(b) How can the  $pH$  value of urine be determined?
- 5 Give chemical antidote for poisoning from the following  
morphine                      corrosive sublimate  
carbonic acid                  arsenic

### Maryland Personal

Dr Norman Cameron, associate in psychiatry, Johns Hopkins University School of Medicine, Baltimore, has resigned to take charge of the laboratory for experimental psychology and psychopathology at the Payne Whitney Clinic of the New York Hospital, New York City

### Fund to Aid Worthy Students

The University of Cincinnati recently received a bequest of \$10,000 from the estate of Mrs Ida B Rulison to establish a fund bearing her name to aid "needy and worthy medical students in such manner as the board of trustees of said university shall in their discretion deem most advisable for scholarships"

### Missouri Personal

Dr Charles H Neilson, associate dean of the St Louis University School of Medicine, has been appointed to the state board of health by Governor Stark for a term ending Dec 12, 1942

—

Autopsy revealed a firm sausage-like enlargement of the distal 10 cm of the left ureter, from 3 to 4 cm in diameter firmly fixed to the surrounding tissues. The lumen of the distal 7 cm was distended to from 1.5 to 2 cm by a soft papillary, partially necrotic tumor, and a diffuse gray tumor was seen throughout the thickened wall. A continuation of this growth extended into the left lobe of the prostate and into the bladder wall, pushing up the mucosa. The regional and periaortic lymph nodes were not involved, but there were multiple metastases in the pleura of both lungs and scattered nodules in the lung parenchyma and liver. None were found in the bones. No other source of primary tumor was found.

Microscopic examination of the ureter (fig 2) showed the ureteral tumor to arise from and replace the mucosa. The tumor cells showed both papillary stalk formation and solid nests of squamous cells, sometimes with keratinization which extensively invaded the wall. The bladder and prostate showed extension of squamous cell carcinoma from without.

The final diagnosis was partially papillary and partially solid squamous cell carcinoma (grade 3) of the distal end of the left ureter, with extension to the bladder and left lobe of the prostate and metastases in the lungs and liver.

**CASE 3**—E. L., a white man aged 65 who entered the Los Angeles General Hospital Dec. 12, 1936, had first noticed painless hematuria one year before. Three months before the bladder had filled with clots, but for six weeks there had been no bleeding. He complained of pain in the perineum running down both legs and swelling of the left leg. There were marked loss of weight and weakness. The patient was well developed, and a general examination gave negative results. The kidneys were not palpable. The external genitalia were normal. With rectal palpation the prostate seemed small, the right lobe was soft and the left firm. To the upper part of the left lobe was attached a stony-hard fixed mass which extended up beyond the palpating finger.

Roentgenograms of the kidneys, ureters and bladder were normal. An intravenous urogram showed a normal right kidney but no dye on the left in thirty minutes. A cystogram

Fig 3 (case 3)—Wall of ureter showing portion invaded by nests of fairly well differentiated squamous cells.

was reported as showing encroachment on the bladder by a mass from underneath. There was a small amount of residual urine, which showed many red and occasional pus cells. The value for nonprotein nitrogen was 30 mg.

Cystoscopic examination showed a bar type prostatic obstruction. The interureteric ridge was hypertrophied, but the meatuses appeared normal. Back of the trigon near the left meatus a tumor mass invaded from below. Indigo carmine

came intensely from the right but not from the left. Catheters met an impassible obstruction just above the left meatus but caused no bleeding. No ureterogram could be obtained for the left side. Biopsy of the mass showed squamous cell cancer. A clinical diagnosis of cancer of the bladder was made. The mass was fulgurated heavily, and the patient was referred to the California Institute of Technology for high voltage roentgen therapy. A total of 6900 roentgens was given in four weeks.

Fig 4 (case 4)—Lateral wall showing widespread invasion by squamous cells.

through four portals. The disease progressed, loss of weight and strength was rapid. The liver enlarged, the left leg became markedly swollen and death occurred one month after the last roentgen treatment.

At autopsy the distal extravascular 8 cm of the left ureter was seen to be profoundly thickened by a hard tumor growth so that it was from 2 to 4 cm across, and it was firmly bound to the pelvic tissues, especially at the pelvic brim, where tumor had extended into and occluded the common iliac vein. The midportion was from 1 to 2 cm thick. Above the tumor there was marked dilatation of the proximal 10 cm of the ureter and of the pelvis, by thick pus. Marked fibrosis of the renal parenchyma was present. The mucosa of the bladder was intact and no evidence of tumor of the bladder was seen. Massive metastases were found in the liver, and several biliary lymph nodes contained tumor. Soft tumor nodules were found in the fourth lumbar and upper sacral vertebrae. No tumor was found in other parts of the body.

Microscopic examination through various levels of the ureter showed a solid squamous cell tumor growth (grade 2) arising from and replacing the mucosa and in many places growing throughout the entire wall in irregular nests (fig 3). Some of the cells showed keratinization, but most of them were fairly small and poorly differentiated. The metastases showed similar tumor.

The postmortem diagnosis was solid nonpapillary, poorly differentiated squamous cell carcinoma (grade 2) of the lower and middle portion of the left ureter, with stenosis and pyonephrosis, fibrosis of the renal parenchyma, metastases to the liver, biliary lymph nodes and spine, and tumor thrombosis of the left common iliac veins.

The tumor which pushed up the bladder mucosa and was destroyed by fulguration by the clinician was an extension from the ureter. The only bladder growth present at autopsy in multiple sections was found in the mucosa of the mural portion of the ureter. The extent of the tumor-bearing portion of the ureter from the bladder to 10 cm from the pelvic junction was unique.

CASE 4—F W, a white woman aged 22, the mother of three children, a patient of Dr R G Tucker, entered the Alhambra Hospital Aug 8, 1933, complaining of constant severe pain in the left part of the pelvis and the left thigh of three months' duration. This pain had increased until opiates were required. There was loss of weight and moderate fever with night sweats. There was no dysuria or gross hematuria. The young woman was pale, in pain and evidently ill. An extremely tender mass 5 cm in diameter was found just above the pelvic brim on the left side. A mass was palpated high in the side of the pelvis and considered to be tubal. Pelvic examination otherwise showed only a lacerated cervix without tumor. The head, chest and extremities were normal. The urine did not contain blood or pus. A blood count showed 4,100,000 red blood cells, 17,500 leukocytes, hemoglobin content 60 per cent, neutrophils 75 per cent, lymphocytes 21 per cent, monocytes 3 per cent and basophils 1 per cent. No urologic study was made.

The clinical diagnosis was tubo ovarian abscess. Through a lower midline incision the pelvic organs were found to be normal and the mass was found to be retroperitoneal over the psoas muscle. Fluctuation was present and the mass was drained. Much necrotic tissue and pus was evacuated. Biopsy of the wall of the mass showed squamous cell carcinoma (grade 3), origin undetermined. Profuse drainage continued for four weeks, with the temperature up to 102 F. Severe pain persisted, the mass enlarged and edema of the left leg developed. Death occurred September 12.

At autopsy the left ureter showed a roughly sausage-shaped tumor, in places from 5 to 6 cm thick, involving a segment 12 cm long, beginning 8 cm from the kidney. It had invaded widely the retroperitoneal tissues, especially the pelvic brim and psoas muscle. Large areas of suppurative (*Staphylococcus aureus*) necrosis were found throughout the mass. The distal 4 cm of the ureter was not involved by tumor. The ureter above the growth was distended to 3 cm in circumference and was filled with thick purulent urine, as were the markedly dilated pelvis and calices. Many small abscesses were present in the kidney, which measured 12 by 6 by 4.5 cm. Metastases were present in the left iliac and periaortic nodes. Numerous septic infarcts were found in both lungs. No extra-ureteral primary tumor was found.

Microscopic examination showed a solid squamous cell growth arising from and replacing the mucosa and invading the markedly thickened wall and the periureteral tissue. Some portions showed keratinization, and other portions showed less differentiated small polyhedral squamous cells (fig 4).

The final diagnosis was solid, nonpapillary squamous cell carcinoma (grade 3) of the middle and lower portion of the left ureter, with pyemia due to *Staphylococcus aureus* and infarcts in both lungs.

CASE 5—H W, a white woman aged 72 was seen at home in the terminal stages of her illness by Dr R C Olmsted, and no urologic examination was possible. She died with symptoms of obstructive vomiting and a tentative diagnosis of carcinoma of the pylorus was made.

At autopsy the distal third of the right ureter was seen to be thickened to 3 cm in diameter by a tumor-bearing portion involving a segment 3 cm long the lower border 2.5 cm above the bladder. The lumen was completely obliterated. Extension into the broad ligament had occurred and there was widespread metastasis to the abdominal lymph nodes, with many implants in the peritoneum. Marked hydro ureter and hydronephrosis were present. The duodenum showed an indurated benign ulcer 8 cm broad and 8 mm deep with marked fibrosis and stenosis of the pylorus. There was no primary malignant growth in any organ except the right ureter.

Microscopic examination showed the tumor of the ureter (fig 5) to arise in the mucosa and to grow through the entire wall and into the periureteral tissue in the form of irregular nests of squamous cells. An occasional pearl was seen but most of the cells were less differentiated and nonkeratinized. The metastases were similar.

The diagnosis was primary squamous cell carcinoma (grade 3) of the right ureter with marked hydro ureter and hydronephrosis, metastases to the abdominal nodes and peritoneum, and indurated benign ulcer of the duodenum with pyloric stenosis.

CASE 6—J M, a white man aged 69, who entered the Los Angeles General Hospital Nov 18, 1935, had been in excellent health until one year previously, when sciatic pain developed on the right side. After two months this disappeared, but then he began to have pain in the right side of the pelvis which later moved to the upper part of the abdomen. During the year he had lost 50 pounds (23 Kg), and in the last three months he had become jaundiced. Twice in the last two months he had had terminal hematuria. He was nauseated and acutely ill on admission.

Examination showed emaciation and moderate jaundice. The liver was nodular and extended almost to the umbilicus. A tender mass 6 cm in diameter was present in the right upper posterior quadrant of the abdomen and moved with respiration. The lungs were normal. The blood pressure was 160/90. The prostate was reported normal. The patient went to the general medical ward because of the jaundice and was not studied urologically. A tentative diagnosis was made of cancer of the right kidney or cancer of the stomach. He died five days after admission.

At autopsy, performed by Dr Newton Evans and Dr C B Coggin, the right ureter showed a solid tumor growth 2 cm long at a level 5 cm above the bladder, thickening it to 2 cm across and producing complete obstruction. Marked distention of the ureter and pelvis by thick purulent exudate was present above the tumor and there were numerous abscesses in the renal parenchyma. Metastases were found in the common iliac and lower periaortic lymph nodes and in one left supraclavicular node, and massive metastases were present in the liver, which weighed 3,900 Gm. No primary tumor was found in any organ other than the ureter.

Microscopic examination of the ureter (fig 6) showed replacement of the mucosa by an irregular growth of poorly differentiated nonkeratinized squamous cells, varying considerably in size and shape and showing moderate hyperchromatism of the nuclei. The wall of the organ was infiltrated and markedly thickened by a similar growth. The metastases in the liver were of similar structure.

The diagnosis was solid, nonpapillary, poorly differentiated squamous cell carcinoma (grade 3) of the lower end of the right ureter, infected hydro ureter and hydronephrosis, multiple renal abscesses, metastases in the iliac, periaortic and supraclavicular lymph nodes, and massive metastases to the liver with moderate jaundice.

#### COMMENT

Of particular interest is the widespread extension of tumor in all the cases except case 5. The sausage-like growth in cases 2, 3 and 4 was quite striking. Metastases were found in all our cases.

#### SUMMARY

1 In our six cases of proved as well as in 133 cases compiled from the literature, the tumors were most commonly found in the end of the ureter, and in about 30 per cent they protruded into the bladder. They varied from minute papillary growths to widely invading massive squamous growths. Their histologic picture was similar to that of carcinoma of the bladder.

2 Hematuria, pain and palpable abdominal mass (usually a hydronephrotic kidney) were the chief clinical features.

3 Diagnosis is based on bleeding from one ureter, together with obstruction or a filling defect as shown by urogram, or by observation of a tumor protruding into the bladder.

4 The treatment of choice is nephro-ureterectomy. A two stage operation is much the safest. Late diagnosis often limits treatment to lesser surgical intervention and palliation.

5 The prognosis is bad. However, three eight year cures have been reported.

NOTE—Since this paper was written five additional cases have been described by Charles C Higgins (Primary Carcinoma of the Ureter *Ann Surg* 108 271 [Aug] 1938).

HEMATOGENOUS TUBERCULOSIS  
AND SILICOSISTHE ROENTGEN DIAGNOSIS OF  
TUBERCULOSILICOSIS

JACOB GERSHON-COHEN, M D

AND

LOUIS COHEN M D

PHILADELPHIA

## HEMATOGENOUS TUBERCULOSIS

Tuberculosis is an infectious disease which it is conceded may invade the blood stream. The acute forms of miliary tuberculosis seen in the young and often as a terminal phase of chronic ulcerative pulmonary tuberculosis are the forms of blood stream infection familiar to the clinician. More occult and less well recognized are the subforms of miliary tuberculosis which heal. These are more often recognized by the roentgenologist than by the pathologist or clinician. There is plenty of laboratory evidence to prove the occurrence of tuberculous bacteremia without lethal consequences, but it is not our purpose to enter into this somewhat controversial aspect of the problem. We believe not only that the tubercle bacillus does gain access to the blood stream more frequently than usually admitted but also that certain definite histologic reactions follow which are demonstrable in roentgenograms of the lungs, that is, of course, if the lesser circulation becomes involved. These reactions confirm Ranke's<sup>1</sup> ideas about the allergic histologic changes seen at this time. The reaction is a marked lymphocytic invasion of the perifocal tissues about the tubercle with a marked exudative response. This may be followed by rapid central necrosis and cavity formation or by slow resolution with or without scar tissue formation. The various manifestations of this phase of the disease have been completely analyzed and classified on a clinical basis by Neumann.<sup>2</sup> The remarkable thing about this classification is that, though done on a clinical basis without much aid from roentgen studies, it is admirably suited for roentgenologic use. His divisions are (1) typho-tuberculosis of Landouzy, (2) proliferative primary complex, (3) polyserositis and pleurisy in its various forms, (4) tuberculosis fibrosa diffusa, (5) tuberculosis fibrosa densa, (6) fibro-ulcerative tuberculosis following fibrosa diffusa or densa and (7) "phthisis cavitaria ulcerosa."

These terms are very descriptive and examples of each of the forms, once seen, are easily remembered. We are here concerned only with diffuse fibrous and discrete miliary or acinonodular forms because of their close resemblance to silicosis, but their appearances vary according to such readily recognized factors as bacterial virulence, resistance of the host, morphologic and functional changes of the parts involved and frequency and intensity of seeding of the organism. Characteristic of all forms is a tendency to resolution or fibrosis of the lesions with only a mild systemic reaction of the host (fig 1). This results in the exhibition of few symptoms, among which fatigue is most prominent

Probably more than half of the cases end in healing, often without recognition of the cause by the family physician. Only when trigger symptoms appear, like hemoptysis, cough and expectoration or pleurisy does the physician suspect a tuberculous basis. In serial roentgenograms the lesions are characterized by a pre-dominance of fibrous tissue formation, which frequently leads to calcification (fig 2). (It is precisely these changes that often mimic silicosis but which present, none the less, differences in pathogenic characteristics.) Patients who recover after having passed through this stage of tuberculous infection, though they may have advanced through the progressive ulcerative forms with widespread intracanalicular extensions, often live to old age, with permanent scars demonstrable in serial roentgenograms. It seems true that lung reinfection is more frequently encountered in these tuberculous patients than in subjects who have escaped tuberculosis. Barring such supervening accidental infections, however, these subjects may live to old age, only to succumb to heart failure because of the heavy load the right side of the heart sustains as a result of the increased resistance in the lesser circulation.<sup>3</sup>

## SILICOSIS

Changes develop in the lungs in silicosis very similar to the later changes of Ranke's allergy.<sup>3</sup> These changes are essentially the stage of endothelial phagocytosis and the stage of fibrous tissue proliferation. The fibrosis may be predominantly linear or miliary and nodular, often it is mixed. It is said to be progressive even after inhalation of the dust particles ceases, but the burden of proof rests with the proponents of this concept,<sup>4</sup> whose records show an extremely high incidence of supervening infections,

Fig 1—1 disseminated acinonodular tuberculosis in a patient 44 years old, Feb 23 1934. Tuberculosis was first diagnosed nine years before. When this roentgenogram was taken the patient was losing ground rapidly with cough and hemoptysis prominent symptoms. After two months of conservative treatment in a sanatorium a phrenicectomy was done on the right side because a cavity developed in the upper lobe and a pneumothorax could not be done. The cavity blocked shortly after phrenicectomy. Most of the widespread infiltrations in both lungs resolved or organized. B the patient was clinically well when this roentgenogram was taken March 26 1938.

particularly tuberculosis, so that death can hardly be ascribed to progressive silicosis. In the absence of further exposure to dust, simple silicosis may progress to a point characterized chiefly by a slight increase in the size of the nodular islands of fibrosis, with only slight aggravation of the resultant emphysema. Healing nodular tuberculosis, on the other hand, regresses, the nodules become smaller, sharper and often calcify

fied if not completely resorbed. Aggravation of the emphysema is theoretically the same as in silicosis. The ultimate degree of nodular fibrosis reached in silicosis is determined by the amount of retained silicious material. When this limit is reached there is a substantial degree of arrest if tuberculosis does not complicate the picture. Simson and Strachan<sup>5</sup> concluded that "a very considerable proportion escape this complication throughout." While our serial studies do

Fig 2—A moderate fibro-ulcerative cavernous tuberculosis in the upper lobes of both lungs April 2 1930. In the greater circulation only the kidneys were suspected of involvement because of a persistent faint trace of albumin for many months. With conservative treatment the processes in both lungs healed in about eight months with fibrosis and calcification of the linear and nodular infiltrates. B taken April 13 1938 shows the irregularity in the size and distribution of the lesions.

not extend over so long a period, our observations strongly support this view.<sup>6</sup>

The South African investigators have long recognized a form of tuberculous complication which is like hematogenous tuberculosis in that there is a marked tendency to arrest of the disease. This tendency is particularly striking in cases of the fibrous and acino-nodular forms, which so closely simulate silicosis itself in the roentgenogram. The condition in this large group of cases is designated by them "tuberculosilicosis" to distinguish it from the older, better understood "silicotuberculosis." While the lesions of the "infective," or "tuberculosilicotic," type may occur in nodular form, the nodules are characteristically irregular in size and outline. Sometimes large dense areas of massive fibrosis develop, but they hardly possess the appearance of classic unmodified silicosis or tuberculosis (fig 3). These infective lesions can be recognized roentgenographically. Simson and Strachan<sup>5</sup> have shown that the inoculation of preparations from infective silicotic lesions which showed no positive evidence of tuberculosis to the naked eye or microscopically gave a majority of positive results for tuberculosis. This has led their bureau to classify under the term "silicosis of the infective type" those cases in which lesions of the character described are present but in which nevertheless the accepted local or general indications of active tuberculosis are not present. Such cases comprise a large distinctive, clinical and radiographic group.

#### TUBERCULOSILICOSIS

We have had ample opportunity to see the evolutionary hematogenous tuberculous changes in long serial studies at Eagleville Sanatorium, Eagleville Pa. In the Millville Hospital, Millville, N. J., a large number of

routine serial studies of men who work in the sand-pulverizing industries are in progress. Comparisons with the cases observed at the tuberculosis sanatorium were thus possible. These studies yield concepts of the pathogenesis and pathology of both diseases not readily reconstructed by the pathologist from postmortem studies. Chief reliance falls on the roentgenologist, not the pathologist, for establishing the diagnosis in symptomless cases of infective silicosis, or tuberculosilicosis. In the roentgenograms the number of scars, their type, their distribution and the secondary changes they produce can be studied. The most important factor in these changes is the length of the infective period.

The chief diagnostic stumbling blocks in building the picture of tuberculosilicosis have been the absence of evidence of tuberculous infection in postmortem examinations, the paucity or absence of clinical symptoms of tuberculosis during life and, most important (or at least the factor most stressed), the absence of tubercle bacilli in the sputum. Another difficulty is the fact that the course of the disease is chronic without the patient or the physician realizing the true cause of the mild symptom complex in the early stages. Only when erosion of a lesion into a vessel produces hemoptysis or development of a cavity results in cough and expectoration with toxic symptoms, in part probably ascribable to secondary infection, does the suspicion of tuberculosis develop. Even when the condition is diagnosed at this stage there is often apparent arrest of the disease, especially if the provoking agent is no longer effectively operative. The residual scars of this phase of the disease do not resemble the later manifestations of simple silicosis or of the discrete miliary or nodular forms of hematogenous tuberculosis. The roentgen diagnosis is thus less difficult because the early linear scarring of initial silicosis is "added" to the previous scarring of tuberculosis. This may not be evident at first because the tuberculous fibrosis is so well organized and masked by the compensatory emphysema that its presence is not suspected, but there develops nevertheless a concentration of fibrosis in patchy areas, usually in the upper lobes. This

Fig 3—Tuberculosilicosis. A man aged 46 had tuberculosis when he was 19 years old at which time he was sick nine months. He recovered completely and never had a recurrence. For several years he worked at an emery wheel and shortly before roentgen examination he had hemoptysis. The slight cough and dyspnea he had had for two years were regarded by him as annoying but not otherwise significant. To change his occupation immediately and to treat him for tuberculosis was the course chosen by his physician.

ends in an asymmetrical distribution which is the telltale point of differentiation between simple silicosis and tuberculosis. The roentgenologist, then and not the pathologist, can make a positive diagnosis, and he need not be deterred by the clinician who disagrees because typical physical signs are lacking or because the sputum is free of the tubercle bacillus. Auerbach's<sup>7</sup> disagreement with Beattie, Ichert and Gardner about the fibrotic nature of tuberculosis in

<sup>5</sup> Simson F. W. and Strachan A. S. Silicosis and Tuberculosis publication 36 (vol. 6) South African Institute of Medical Research Johannesburg Union of South Africa 1935 p. 567. Report of Miners' Health Medical Bureau for Three Years Ended 31st July 1935. Pretoria Union of South Africa Government Printer 1936 pp. 9-19.

<sup>6</sup> Routine serial studies are made of employees in the sand-pulverizing industries of southern New Jersey under the direction of Dr. H. S. Braun of Millville, N. J.

<sup>7</sup> Auerbach Oscar. The Pathology of Pneumoconiosis. Quart. Bull. Soc. Am. Ho. p. 2: 327 (Oct.) 1936.

silicosis in their postmortem studies might have been resolved if the pathologic changes noted in serial roentgen studies had been included in their observations. It is not always easy for the pathologist to construct his archeologic histologic picture at necropsy if he has not had roentgen data of the disease when the pathogenic tide ebbed toward healing with resolution, fibrosis and calcification. The clinician, in his field, may be led astray in his diagnosis because of the absence of toxic symptoms or deterioration in general health. He may not be able under these conditions to demonstrate the clinical counterparts of the pathologic changes, even areas of large consolidations in the upper lobes, and pleural thickening or other indications of latent or arrested infection are easily missed.

Simple silicosis, if progressive or intense enough may lead eventually to chronic bronchitis and emphysema with heart failure on the right side. Since clinical hematogenous tuberculosis too may progress to a similar lethal ending it is not at all surprising that when the two conditions cross an augmented tendency to interstitial fibrosis ensues, no matter which is the more predominant or which came first. If silicosis predominates, a more rapidly developing bronchitis and emphysema

Fig 4—Tuberculosilicosis. A, Sept. 11, 1936 and B, April 23, 1938. The roentgen diagnosis was based on the irregularity of distribution and size of the acinonodular infiltrations and the diffuse hazy infiltration in the upper lobe of the right lung. A man aged 51 who worked for seven years as a screener in a sand pulverizing plant had pneumonia at 18 and influenza at 40. He had cough and expectoration occasionally with hemoptysis for eight months after the influenza. The roentgenograms suggest a possible tuberculous basis for these manifestations. While there have been only slight changes in the appearance of the lungs during two years of serial observations withdrawal from further exposure to silica before the pathologic changes advance to the silicotuberculous form of the disease is highly recommended.

results, if tuberculosis predominates the symptom complex of tertiary bronchopulmonary tuberculosis with intracanalicular extension results. Since tuberculosis is predominant and not sufficiently altered by the silicosis it is called silicotuberculosis. On the other hand, just as hematogenous tuberculosis may become arrested, so with limited exposure to silica the silicosis in a subject with hematogenous tuberculosis also may become limited. Then the interstitial fibrosis may appear to remain stationary although more extensive in the areas where the lesions of the two diseases exist together (fig 4). In 89 per cent of 150 cases in this category, Simson and Strachan found no postmortem evidence of active tuberculosis. Even infective silicotic lesions of the massive type tend to be only slowly progressive though they lead ultimately to a condition of active tuberculosis.

Asymmetrical distributions of linear and nodular fibrosis in persons with silicosis would therefore seem sufficient in themselves to establish the diagnosis of infective silicosis, with tuberculosis in the vast majority

of cases, labeled the etiologic infection. The term tuberculosilicosis is better reserved for this condition to distinguish it from silicotuberculosis, which might be used to designate the type in which tuberculosis is so predominant as to be diagnosed easily. This is so true that Watkins-Pitchford<sup>4</sup> believes that the pathologic process in almost all the cases of "simple silicosis" on the Rand is fundamentally the same as that of tuberculosis with silicosis. "The development of what appears to be a condition of simple silicosis, in these days, is probably a pathologically unique result of a tuberculous infection in a latently silicotic individual." The diagnosis of latent tuberculosis with silicosis is much more difficult, and the roentgenologist has done most to set forth the criteria. Our views are an extension of those commonly held on this subject and are in essential agreement with the points made by Pancoast and Pendergrass.<sup>8</sup> Their criteria for diagnosing tuberculosis in the presence of silicosis are (1) deviation of the trachea, (2) fibrosis at the periphery of the lungs, especially apical, and (3) marked thickening of the pleura. These are the changes that follow in the wake of organized tuberculous processes, especially those designated manifestations of "hematogenous tuberculosis." Our conclusions simply add further support, as well as a broader concept, to the diagnosis of this form of the disease. We recommend that this type of simultaneous infection be classified under a separate heading. This is in line with the recommendations of Pancoast and Pendergrass, who suggest dividing silicosis into types rather than into stages, as if silicosis were always of the same type. To designate this form tuberculosilicosis in accordance with the practice of the South African workers seems logical. Then the term silicotuberculosis might be reserved for the frankly tuberculous process associated with silicosis when the bacteriologic diagnosis of tuberculosis is positive. The practical significance of emphasis on these points of diagnosis is that the morbidity and mortality rates for silicosis might be materially improved if proper changes were made in the occupation of the silicotic person at this stage of his tuberculous infection. The well known aggravating influence progressive silicosis has on tuberculosis could thus be avoided. This would result in fewer cases of tuberculosilicosis becoming silicotuberculosis—the terminal form of the disease—and thus improve the management of employee compensation, an increasing problem in this field.

#### ABSTRACT OF DISCUSSION

DR. PHILIP J. HODES, Philadelphia: The most difficult problem of physicians interested in silicosis today is that of the pulmonary infections which complicate this disease and tuberculosis is by far the most important. For years two types of tuberculosis, adult tuberculosis and childhood tuberculosis, have been recognized. Men familiar with silicosis have recognized a third type, silicotuberculosis, which has different characteristics. In discussing a fourth type, hematogenous tuberculosis, the authors have entered a controversial field. In carrying the problem of hematogenous tuberculosis into the field of silicosis, they are opening a new field, in which many physicians are

lost at present, but because of the importance of the problem it behooves us to investigate it along the lines suggested by them. At present it is difficult to reconcile ourselves to the thought that a disease as variable as tuberculosis can combine with a disease as variable as silicosis and still retain its identity well enough to be of prognostic value. I believe that repeated examinations are of paramount importance in determining the prognosis for patients with silicosis plus infection. The authors referred to cardiac disease due to silicosis. I have never seen cardiac damage which could be attributed directly to silicosis. The patients who died cardiac deaths invariably presented complications which were superimposed on their silicosis. I should like to ask what effect this type of tuberculosis has on the sedimentation rate in silicosis. Are the roentgen manifestations of hematogenous tuberculosis the same in industries with a silica hazard other than the sand-pulverizing industries? I should like to know whether syphilis influences the roentgen manifestations of this disease. In treating patients with silicotuberculosis, one might be tempted to induce artificial pulmonary collapse. Experience has taught that silicosis with infection does poorly after pneumothorax therapy. Silicosis, especially silicosis with infection, has been looked on as a progressively fatal disease. I agree with the authors as to the more optimistic outlook one may assume for silicosis with infection. The series of patients presented bears testimony to the good which can be done patients with this disease if they are properly handled.

DR. FREDERICK SLYFIELD, Seattle. In the first film that was shown, I should like to ask the authors whether they made a diagnosis of hematogenous tuberculosis—I mean before subsequent film added light on the subject—and, if so, how.

DR. PHILIP H. PIERSON, San Francisco. I have been interested in the diffuse miliary nodules seen in persons with tuberculosis, oftentimes not associated with clinical manifestations. I have thought that I could correlate them with sun bathing which was carried perhaps to the point of acquiring a heavy coat of pigmentation. I should like to know whether the authors feel that this may be a factor in this wide dissemination. I think from the minute distribution of these nodules that a bronchial artery spread, rather than a pulmonary artery spread, may be taken into consideration as a factor in these small nodules.

Dr. Marc Jaquerod of Leysin has published a book on the difference in appearance in bronchial artery spread and pulmonary artery spread, expressing the belief that there is a distinction between the two. Another explanation for these fine, discrete nodulations may be a reaction in the lymphoid tissue present in the branching of all bronchioles. This reaction might be similar in the roentgenogram to a hematogenous spread. I wondered whether the authors made a diagnosis of silicosis in that prenodular stage and whether one is safe in committing oneself to the view that the man has silicosis when the disease is only in this stage of increased linear marking.

DR. JACOB GERSHON-COHEN, Philadelphia. The roentgenologist may diagnose hematogenous pulmonary tuberculosis and silicosis by careful study of the distribution of fibrosis and calcification. If the fibrosis is more concentrated in isolated areas, especially in the upper lobes this is sufficient evidence to justify suspecting a tuberculous infection complicating silicosis. In many forms of hematogenous tuberculosis the only roentgen change may be localization of linear or nodular fibrosis in the upper lobes unassociated with toxic symptoms or tubercle bacilli in the sputum, and the same holds true if this kind of infection coexists with silicosis.

DR. LOUIS COHEN, Philadelphia. Hematogenous tuberculosis is being overlooked as a clinical chronic pulmonary entity in this country and not being overlooked in other countries in spite of the fact that Dr. Hodes says the point is controversial. In Vienna one will see wards full of patients with what physicians call hematogenous tuberculosis; they prove the diagnosis at autopsy and treat the disease with old tuberculin because they feel it is in the blood stream and the problem consists in picking up the immunity of the patient. I don't think that any of the patients had syphilis because all the patients at the sanatorium have routine Wassermann and

Eagle tests. The sedimentation rates are up in all of them. I am glad Dr. Hodes brought up the question of failure of the right side of the heart because we are not convinced that tuberculosis or tuberculosis plus silicosis causes it. A great deal of work is being done along that line, and a great deal of argument has been raised pro and con. I believe the prognosis of silicosis is much less dangerous than one is given to believe. I believe the silicotic patient is dyspneic and emphysematous, and even with tuberculosis—if he has the benign hematogenous form and is picked up early and taken out of his industry—he can go along and do as well as any other man of his age. He may be dyspneic on climbing a hill or walking up steps. We diagnose all these hematogenous conditions first by the x-rays and second by the clinical symptoms. The patients are not all sick, they appear to be in a benign condition and may or may not cough or expectorate and have what looks like extensive symmetrical evenly distributed advanced tuberculosis. I have now under my care four people for whom a diagnosis of hematogenous tuberculosis was made years ago and they now have renal tuberculosis—four people with positive sputum and tubercle bacilli in the urine. I don't know anything about the effect of the sun's rays except that the group of physicians I work with are much against the use of ultraviolet therapy in active tuberculosis. I believe these hematogenous lesions are in the interstitial tissue of the lung and the lesser circulation.

## THE MANAGEMENT OF TUBERCULOSIS OF THE CERVIX UTERI

A REPORT BASED ON 191 CASES SIX CASES BEING REPORTED FOR THE FIRST TIME

DONALD C. COLLINS, M.D.

LOS ANGELES

Tuberculosis of the cervix uteri merits the serious consideration of the entire medical profession. It is significant that its gross appearance often closely resembles that of carcinoma. Tachezy<sup>1</sup> and Tommaselli<sup>2</sup> have both drawn attention to instances of tuberculosis and carcinoma existing in the same uterus. Only sixty-two articles on this subject were listed in the Index-Catalogue of the Library of the Surgeon General's Office, United States Army, up to the year 1914. In few recorded cases in the past has the condition been correctly diagnosed before the cervical lesion was studied under the microscope. Undoubtedly in many instances it has been lightly dismissed as representing far advanced cervical carcinoma with a consequent hopeless prognosis. This is unfortunate because many patients could have been restored to a full and useful life had proper treatment been instituted.

Counsellor and I<sup>3</sup> presented a study on this subject in 1934. We added one new case and listed 108 other cases collected from the literature. This presentation is a continuation of that work. The eighty-two new examples mentioned here were not included in our previous report. This study is therefore based on a consideration of 191 instances of this disease. Forty-one new cases have been described since 1933 in the available literature at my command. Thirty-five additional cases have been found recorded prior to the

From the Surgical Pathology Laboratory, Los Angeles County General Hospital and the Departments of Surgery and Pathology, College of Medical Evangelists.

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

year 1934 Parrain,<sup>4</sup> in his graduation thesis on this subject at Paris in 1935, estimated that up to then 216 examples of secondarily contracted tuberculosis of the uterine cervix had been described together with

Fig. 1 (case 1)—Biopsy specimen from the cervix showing typical Langhans giant cells and tubercle formation. Reduced from a photomicrograph with a magnification of 240 diameters.

forty-four instances of true primary infection. Since Parrain's<sup>4</sup> study, reports of thirty-four new cases have been found.

Lisfranc<sup>5</sup> is said to have been the first to identify tuberculosis of the cervix. In 1851 Geil<sup>6</sup> described this disease so well that little has been added in the ensuing eighty-seven years. Cohnheim<sup>7</sup> during 1879 showed that coitus with a tuberculous man could cause this condition. In 1883, one year after Koch's epochal discovery of the tubercle bacillus, Victor Babes<sup>8</sup> isolated the same organism from the vaginal secretions of a patient who was suffering from tuberculosis of the cervix uteri.

In America J. Whitridge Williams<sup>9</sup> in 1892 and John B. Murphy<sup>10</sup> in 1904 reviewed this entire subject and stabilized its treatment. Time and space do not permit the mention of many notable articles that have since appeared dealing with this condition. The recent contributions of Counseller and Collins,<sup>3</sup> Morillo-Una,<sup>11</sup>

Finlaison,<sup>12</sup> Lester<sup>13</sup> and Danforth<sup>14</sup> are valuable additions to our knowledge of this disease.

Among 33,580 reported instances of female genital tuberculosis there were 133 (0.3961 per cent) of tuberculosis of the cervix uteri. Of these 133 cases thirteen (9.776 per cent) were undoubtedly instances of primary tuberculosis. In approximately 42 per cent of these cases there was associated active pulmonary tuberculosis. Williams<sup>9</sup> said that, in 0.16 per cent of women suffering from pulmonary tuberculosis, tuberculosis of the uterine cervix subsequently developed. In the histologic examination of 44,484 operative specimens reported in the literature there were only eleven (0.024728 per cent) proved instances of this disease.

Tuberculosis of the cervix uteri is, in approximately 85 per cent of cases, secondary to a tuberculous focus elsewhere in the body. Such primary foci may be found in the lungs or in either the gastrointestinal or the genito-urinary tract. Of the 185 cases which I have studied from the literature, in 156 (84.318 per cent) there was demonstrable tuberculosis elsewhere. In 102 cases (55.131 per cent) genito-urinary tuberculosis was present in either an active or a quiescent stage. Marriage and pregnancy are two common contributing etiologic factors. Tuberculosis of the female generative tract occurs most frequently in the fallopian tubes and progressively diminishes in fre-

quency as it approaches the uterine cervix. It is believed that this disease usually results from a descending infection spread by contiguity from foci situated higher

there were sixteen proved instances of this type of primary infection. A true example of primary tuberculosis of the uterine cervix must fulfil the criterion of being the only focus of tuberculosis in that patient. Murphy<sup>10</sup> demonstrated that such a primary infection

must usually be an ascending one derived from the outside and introduced into the vagina. Many authors have denied the possibility of this type of tuberculous disease. Wives of tuberculous husbands rarely have primary tuberculosis of the cervix. Cases are recorded in which the husband's disease caused either tuberculous salpingitis or endometritis with a normal intervening cervix.

Tuberculosis of the cervix uteri is classified into four types: the ulcerative, the papillary, the milinary, and the rare bacillary catarrhal. Thus the gross appearance of the cervical lesion may vary widely. The typical lesion is usually ulcerated. The edges are either well defined or undermined and are surrounded by either tubercles or normal-appearing tissue. The adjacent portions of the vagina may be involved, and tubercles may be seen. Bishop<sup>15</sup> expressed the belief that a papular-polypoid lesion was the earliest discernible evidence in many of these cases. Such a lesion may later degenerate into a huge ulcer with ragged undermined edges. Sometimes the specific infection may be deeply situated in the endocervix and reveal little or no external sign of disease. Occasionally one sees a stenotic fibrosing lesion.

Secondary infections are commonly superimposed on these lesions. Varying degrees of bleeding or even severe hemorrhages with accompanying foul leukorrhea are frequently encountered. Microscopically, typical tubercle formation is not commonly seen. Often atypical tubercles composed of only epithelioid and

Fig 4 (case 4)—Biopsy specimen from the cervix showing a Langhans giant cell and incomplete tubercle formation. Reduced from a photomicrograph with a magnification of 180 diameters

lymphocytic cells may be the only evidence on which a presumptive diagnosis of tuberculosis can be made. Acid-fast stains for the presence of the tubercle bacillus in either the microscopic section or the tissue smear may be apparently negative. Inoculation of guinea pigs may prove to be the only reliable method by which a

TABLE 3—Data on Six New Cases Reported in this Study

Case	Age	Important Positive Findings	Tuberculous Foci Elsewhere	Type of Lesion	Treatment	Final End-Result
1	4/9/29 to 5/12/29 O P D 4/10/30	30 Mrs J R Mexican housewife secundipara Wassermann negative sick 1½ years exploratory laparotomy 4/17/29 (patient of Dr Wilburn Smith)	Tuberculous peritonitis and asclites left tubal mass	Ulcer large involving entire cervix	Medical surgery refused	Unknown de ported back to Mexico
2	3/18/30 to 3/27/30	24 Mrs O B S white American housewife secundipara Wassermann 4 plus sick 4 years (patient of Dr H C Seaver)	None	Small polyp posterior lip of cervix	Surgery refused	Unknown left hospital again t our advice disappeared
3	5/23/31 to 6/6/31 10/29/31 to 11/6/31	22 Mrs F A M, Mexican housewife nullipara Wassermann negative sick 1 year 5/28/31 amputation of cervix Sturmdorf method 11/2/31 dilation and curettement for stenosis of the cervical canal returned in March 1938 (patient of Dr L G McNellis)	Tuberculous salpingitis roentgenogram of chest negative now tuberculous of bladder and kidneys	Ulcer anterior lip edges are friable small bled easily	Surgical amputation of cervix 3 months later dilation and curettement was done for a stenosis of the cervical canal	Well until March 1938 now suspected tuberculous of the kidneys and bladder
4	8/21/36 to 9/8/36 reentered October 1937	31 Mrs H T Mexican widow septipara Wassermann negative sick 4 years reentered in October 1937 very ill from progression of tuberculosis (patient of Dr C R Howson)	Advanced bilateral tuberculous of kidneys and lungs with cavitation and of larynx	Ulcer small anterior lip	Medical only no surgery because of advanced general tuberculosis	Left against our advice reentered in Oct 1937 and died 10/4/37 postmortem was refused
5	O P D 5/9/38	37 Mrs L A Mexican housewife nonipara Wassermann doubtful sick 6 months treatment not started as all tests have not been completed (patient of Dr Pence)	Suspected tuberculous of bladder and tubes	Polypoid around external os bled easily	None as yet study not finished as yet	Still under treatment now
6	9/17/37 to 9/24/37	30 Mrs M D Greek widow for 9 years nullipara sick 4 months (patient of Dr T H McLaughlin)	None now pleurisy in 1904	Polypoid anterior lip small bled easily	Radium to lesion 1.5 mg hours in 8 days	Well so far lesion has entirely healed

Additional follow up notes to Jan 17 1939  
Case 3 4/22/38 Removal of proved tuberculous left submandibular lymph node which had acid fast bacilli on bacteriologic study Last seen 7/15/38 when examination of cervix showed it to be well healed and negative  
Case 5, 5/11/38 Roentgenograms of the chest showed moderately advanced pulmonary tuberculosis of the abdomen old tuberculosis of lumbar vertebrae and of mesenteric lymph nodes 5/18/38 Pelvic examination (by malignancy board) Cervix hard nodular but movable with distal third ulcerated bleeding and painful Prosalpinx filled the culdesac 6/7/38 Menstruating asked to return one week later for con ligation of a possible panhysterectomy Patient disappeared left no forwarding address and her present whereabouts were unknown on 1/17/39  
Case 6 Radiation therapy was applied to this patient against my advice The cervical lesion recurred during September 1938 Since then it has steadily enlarged in size until now the entire cervix and vault of the vagina are deeply ulcerated Urinary urgency frequency and dysuria together with rectal tenesmus are quite marked She has refused any surgical treatment (Christian Scientist) despite our warning as to the probable unfavorable final result

correct diagnosis can be established. Biopsy is a quick method of establishing a probable correct diagnosis. A competent pathologist should examine the biopsy specimen, which should be of sufficient size to include all the constituent cellular elements of the cervix in order to permit the making of a correct diagnosis. Removal of such a specimen will not injure the patient, while the issues at stake are of such gravity as to make

other factors are favorable, because usually extensive tuberculous disease of the upper pelvic part of the generative tract is present and must be eradicated if cure is to result. For that reason and because of the rarity of a primary tuberculous infection of the cervix, local treatment of the cervical lesion is not advisable. For similar considerations roentgen and radium therapy will often prove to be disappointing in their end results. The contraindications to the employment of surgery are advanced local tuberculous lesions with extensive involvement of the neighboring bladder or rectum, extensive tuberculous salpingitis, marked secondary infection, the presence of active tuberculous foci elsewhere, cardiovascular disease and senility. The ultimate prognosis in this disease entity is dependent on the type of treatment employed and on whether active tuberculosis is present elsewhere in the body.

For brevity, tables have been used to condense and summarize the data of this study. Table 1 lists the recorded incidence of this disease according to various groupings of material.<sup>16</sup> Table 2 shows the source of tuberculosis of the cervix in 185 cases mentioned in

Fig. 5 (case 5)—Biopsy specimen from the uterine cervix revealing typical Langhans giant cells and partial tubercle formation. Reduced from a photomicrograph with a magnification of 240 diameters.

a correct diagnosis imperative. Syphilis may closely simulate this disease. Earlier medical literature on this subject is replete with reports in which biopsy was not done. Radical operations were performed for the eradication of a supposed carcinoma of the cervix, with a resultant increased operative mortality and morbidity—not to minimize the anxiety that such a false diagnosis caused the patient and her relatives.

Tuberculosis of the uterine cervix is important chiefly in cases in which little or no evidence of tuberculosis is discernible elsewhere in the body. The lesion is often accidentally discovered by the physician in examining the cervix. In a hundred ulcerated lesions of the cervix which grossly resemble a neoplasm the physician could correctly diagnose the lesion as being caused by a carcinoma in ninety-eight. The disease must be differentiated from lesions resulting from hypertrophy of the cervix accompanied by eversion and erosion, myomatous or polypoid changes, gonorrhea, syphilis, actinomycosis, sarcoma and principally carcinoma. Adequate biopsy of the lesion should be of great value in the differential diagnosis if it is considered in conjunction with the history, the physical examination and the laboratory observations.

The treatment of tuberculosis of the uterine cervix should preferably be of a radical surgical character such as abdominal hysterectomy with the possible preservation of one ovary if the patient's condition and

Fig. 6 (case 6)—Biopsy specimen from the uterine cervix showing typical Langhans giant cells and tubercle formation. Reduced from a photomicrograph with a magnification of 240 diameters.

this report, classified as primary and secondary types. Table 3 depicts the important features in six new cases of this disease that are being reported in this paper.

16 The data given in table 1 were obtained from the following sources:

for the first time I believe that case 6 is possibly an example of primary tuberculosis of the cervix. Figure 7 depicts the gross appearance of the lesions in these six new cases.

1930 Wilshire Boulevard

#### ABSTRACT OF DISCUSSION

DR L. A. EMGE, San Francisco. When tuberculosis of the cervix is encountered six times within seven years at one institution, as reported by Dr. Collins, it is in order to call attention to it, however, only a few practitioners will ever encounter it in private practice. In the clinic at Stanford University School of Medicine my associates and I have observed only one case of proved primary tuberculosis of the cervix among about 700 cervixes microscopically examined between 1912 and 1922. Since then we have examined microscopically 3,000 more cervical specimens without seeing another such example. Regardless of

of all unusual lesions or lesions that do not readily respond to treatment. This still is the best means of arriving at a prompt and accurate diagnosis. Surgical destruction still offers the greatest promise for cure, but whenever the disease is part of a more generalized abdominal or systemic tuberculosis, surgical destruction may do more harm than good. Whether cervical tuberculosis is primary or secondary is of purely academic interest and does not change the clinical management.

DR HENRY SCHMITZ, Chicago. Among 1,170 cervixes which were examined microscopically at the tumor clinic at the Cook County Hospital tuberculosis of the cervix was observed in three cases. The impression in each was of a descending infection, as there was a primary infection somewhere in the body. I wonder whether the radical surgical treatment of tuberculosis under these conditions is really safe, in view of the common knowledge of how easy it is to reactivate the primary tuberculous lesion. One patient was in poor condition and died from general tuberculosis. The other two were carefully and slowly treated with radium, and their cervixes healed and never caused them any further difficulty. By this conservative attitude it was felt that in one of the cases, particularly, reactivation of the primary infection was avoided.

DR DONALD C. COLLINS, Los Angeles. I shall follow the time-honored plan of using my five minutes to show slides of these tuberculous lesions, for which I did not have time earlier.

Fig 7—Gross appearance of the cervical lesions in this study.

the variations reported in its incidence, tuberculosis of the cervix is rare and I doubt that 0.16 per cent of all women suffering from pulmonary tuberculosis experience its development in the cervix, as quoted from Williams by Dr. Collins. Progress of the disease is slow and is not accompanied with rapidly progressive invasion typical of cancer. This in itself should attract attention. Furthermore, the evident resistance to conservative treatment certainly should create suspicion. Therefore I cannot share Dr. Collins's pessimism regarding the forgotten or mismanaged case. My acquaintance with a single case left the impression that the local discomfort is so constant and annoying that only a thoughtless practitioner would fail to provide means for an accurate diagnosis. Four patients in Dr. Collins's series were Mexicans. This raises the question of susceptibility of the different races to tuberculosis of the cervix. It is generally assumed that the cervix is resistant to this disease. Of thirty-eight cases of genital tuberculosis studied in our department, in eight there was involvement of the endometrium without extension to the cervix, and in only one, cervical involvement without extension to the fundus or other pelvic organs. Unfortunately there are no criteria to facilitate the clinical diagnosis of this disease except chronicity, and the physician must fall back on the time-honored principle of microscopic investigation

#### X-RAY DIFFRACTION ANALYSIS AS APPLIED IN PNEUMOCONIOSIS

HENRY C. SWEANY, M.D.  
AND  
ROSALIND KLAAS, Ph.D.  
CHICAGO

When attention became centered on silicon dioxide as the cause of fibrosis in silicosis, it was expected that a chemical analysis for the substance would establish the presence or absence of pathologic levels in tissues and body fluids. Work in this direction was carried out by King and his associates,<sup>1</sup> Fowweather,<sup>2</sup> Riddell,<sup>3</sup> Boehme<sup>4</sup> and McNally.<sup>5</sup> As with many similar situations in science, the results obtained by these workers did not measure up to expectations, for a positive correlation between the quantity of silica and the extent of pathologic changes was found not to exist in many instances. A chemical analysis gives only total silica, which may occur in the tissue as free silica or in the combined form of some silicate. If silicates are present to any great extent, a high value for silica will be obtained. If at the same time the amount of free silica is small, there may be little or no fibrosis, for silicates are apparently inert substances, asbestos being a notable exception. It is thus evident that a new approach to the problem was necessary in order to differentiate the harmful from the relatively harmless forms of silica.

The method of Clark and Reynolds,<sup>6</sup> which made use of x-ray diffraction analysis in the identification of quartz in mine dusts, seemed to offer possibilities of application in the field of tissue analysis. The method had been attempted by various workers, but not with

untreated dry tissue Hicks McElroy and Warg<sup>7</sup> studied the residue after trypsin digestion of the tissue, Sundius, Bygden and Bruce<sup>8</sup> after hydrogen peroxide digestion and Kahane and Antoine<sup>9</sup> after nitric, sulfuric and perchloric acid digestion

When Dr G L Clark offered the facilities of the x-ray laboratory at the University of Illinois, together

Jephcott, Gray and Irwin<sup>13</sup> were applying x-ray diffraction analysis to the ash of thirty-five specimens of lung They identified quartz, feldspar and mica as the principal constituents In the continuation of our work, a large number of samples of powdered lung tissue were subjected to analysis The results obtained have been a confirmation of those given in the preliminary reports

#### METHODS

Previous to the chemical analysis, the results of which have already been published,<sup>10</sup> the lung tissue had been hardened in a dilute solution of formaldehyde, dried in vacuo at 70 C, ground to pass a forty mesh sieve and dried further to constant weight at 105 to 110 C For the x-ray study, thin samples were prepared by packing the powdered tissue into disks from 0.2 to 0.3 mm in thickness The x-ray beam, collimated by two 0.01 inch (0.025 cm) pinholes, was supplied by a Philips Metalix tube with a copper target, operating at 20 milliamperes and 27 kilovolt peak The film was

with his cooperation and highly specialized technical assistance, a few representative samples of dried and powdered lungs which had already been analyzed for silica by a standard chemical method<sup>10</sup> were selected

Fig 2—Typical tuberculous calcification

for study The results appeared so promising that a preliminary report<sup>11</sup> was made in 1937 followed by a more complete report in 1938<sup>12</sup> At the same time

Fig 3—Apatite

held in a flat holder at a distance of 5.0 cm from the sample The exposure time was usually seven hours This length of time was made necessary by the use of very thin samples, but with this type of sample the pattern of the inorganic constituents was not masked by the effects of the large amount of organic material present

#### RESULTS

The results of the x-ray diffraction studies are summarized in the table The subjects have been divided into three groups, (A) those showing no pathologic evidence of silicosis, (B) those having silicosis and (C) those with borderline conditions, many of whom had some other form of pneumoconiosis

The normal group included two infants, one having 0.09 per cent silica and the other 0.16 per cent The x-ray pattern showed a broad halo about 3.6 cm in diameter, with more or less scattering about the central spot No sharp lines were present The third patient was a 56 year old nurse (silica, 0.11 per cent) There were no quartz lines, but other crystalline substances were indicated The fourth patient was a housewife who had died of tuberculosis The silica content was 0.05 per cent, the pattern resembled that of the infants' lungs The fifth patient was a 72 year old man who

had farmed all his life. There was a surprisingly high content of silica, 0.63 per cent, although no silicosis was present. There were multiple disseminated calcified and ossified nodular tubercles throughout the lungs—several hundred in all. X-ray diffraction analysis showed no quartz lines. Instead the pattern obtained (fig 1) was similar to that of a typical tuberculous calcification (fig 2) and to the pattern of

Fig. 4—Powdered bone.

apatite (fig 3). The similarity to the pattern of powdered bone (fig 4) could also be noted.

All the specimens for group B, comprising patients with silicosis, showed the 3.34 angstrom unit spacing of quartz. The pattern of quartz (fig 6) is included for comparison. As the concentration of quartz increases, the 4.25 angstrom unit spacing becomes visible. Both lines were strong in the pattern for patient 19 (fig 7), a sand blaster exposed to dust for eight years. Chemical analysis showed 20 per cent silica and pathologic examination revealed solid masses of fibrotic whorls without tuberculosis. Patient 11 is worthy of special mention.

A man aged 29 reported that he had worked in a cement factory at Ottawa, Ill., for six months. Silicosis was not suspected because cement dust is inert and because roentgenograms of his chest always showed a characteristic fibroid tuberculosis. At postmortem examination massive silicotic lymph nodes were found at the hilus of the lung together with many small nodules throughout the bases. Both upper lobes contained fibroid cavities. It was obvious that this man had been exposed to large quantities of silica in work that had not been mentioned in the history. Subsequently Dr. Roswell Pettit of Ottawa, Ill., consented to review this man's work record. After a diligent search he found that the patient had been a cement worker for eight months and that he had spent four months grinding silica for abrasives. This short and apparently heavy exposure was sufficient to give him silicosis, but the silica content of the dried lung tissue was only 0.26 per cent, a value only slightly higher than normal. The X-ray diffraction pattern showed a faint but definite quartz line (fig 8). This case demonstrates clearly that an amount of quartz sufficient to produce fibrosis may be detected by X-ray diffraction analysis.

There were thirteen patients in group C, representing borderline conditions. Patient 20 was a machinist for seven years, but at death the pathologic picture was chiefly that of tuberculosis with a questionable silicotic taint. The chemical analysis revealed only 0.13 per cent silicon dioxide, a value well within normal limits. The X-ray diffraction pattern showed a distinct quartz

line (the exposure time was fourteen hours, twice the usual time) together with the pattern of a tuberculous calcification. A boiler maker, a janitor, a molder and an engineering draftsman had no pathologic or chemical evidences of silicosis. None of them showed the presence of quartz in the diffraction pattern. Patient 24 was a soft coal miner for twenty years. The pathologic picture was that of typical anthracosis, although the silica content was 0.43 per cent. However, no quartz lines were present in the X-ray pattern, instead, the complex pattern of some silicate mineral was obtained (fig 5). Patient 26 was a blacksmith and tool maker for thirty years. There were definite silicotic and anthracotic aspects to the extensive fibrocaceous tuberculosis. Microscopically these properties were all clearly demonstrated. The silica content was 0.22 per cent and there was a definite quartz line in the X-ray pattern. Patient 27 was a hoister in a lead and zinc mine, who died of tuberculosis without any demonstrable silicosis (silica, 0.24 per cent). The presence of quartz was faintly indicated in the X-ray pattern. The silicon dioxide content was just above the pathologic level but as yet no silicosis had developed. Patient 32 was a lead and zinc miner who had worked for eight years in a mine where safety devices were used. There was gross tuberculosis with only a slight suggestion of microscopic silicosis. There was a faint quartz line in the diffraction pattern. The other patients all showed some questionable aspect either in the history or in the pathologic picture, yet the chemical analysis revealed rather large amounts of silica. Except in patient 29 the diffraction patterns all showed the presence of quartz although the exact amount remains to be determined.

#### COMMENT AND CONCLUSIONS

X-ray diffraction analysis is characterized first of all by its great specificity. Nearly all crystalline compounds give patterns distinctly different from all others.

Fig. 5 (case 24)—Lung tissue of coal miner with anthracosis; silica 0.43 per cent; quartz absent.

Hence in a field where chemical methods are not available for identification of the type of silica present and where microscopic methods are inadequate for the study of mineral particles of the size encountered in tissue, the X-ray method gives definite information as to the identity of the crystalline substances present.

Furthermore, a comparison of the patterns with regard to the nature of the lines, i. e. whether they are smooth or dotted, indicates that there is a variation in size of particles from case to case. We conclude that in general the particles are 1 micron or less in diameter. Further work remains to be done on this aspect of the problem.

Another advantage of the x-ray method with the technic described is that the tissue can be used for the analysis unmodified by chemical treatment. Whenever the tissue is digested with some reagent one must

make the questionable assumption that no changes take place in the mineral deposits. In our work such an assumption has been unnecessary.

A further significant feature is the great sensitivity of the method. With our present technic we are able to detect quartz in a concentration as low as 0.2 per cent. This concentration has been found in previous work to constitute the threshold of the pathologic level. Hence, the finding of a faint line on the x-ray film corresponding to the 3.34 angstrom unit spacing of quartz appears to be a good indication of the presence

of sufficient quartz to have already caused, or to be in the process of causing, specific fibrosis in the tissue. The method thus should be of value in medicolegal work whenever difficulty is experienced in determining the presence or absence of silicosis or a silicotic complication.

Finally the method seems to offer possibilities for further development. Clark and Reynolds<sup>6</sup> have made quantitative studies of the amounts of quartz in mine dust. Using a technic similar to theirs, we hope to be able to determine quantitatively, or at least semiquantitatively, the concentration of quartz in tissues. Work in this direction is now in progress. The application of the method to the detection of quartz in sputum is also being studied, with the expectation that a method of diagnostic significance may be developed.

## OPERATIVE INJURY TO THE ANAL SPHINCTER

PAUL C. BLAISDELL, M.D.

PASADENA, CALIF.

Considerable confusion exists concerning the applied surgical anatomy of the sphincter mechanism of the anus as concerned with operative injury to it, with reference here particularly to that surgical trauma necessary to the cure of anal fistulas. What and where is it safe to cut? There are expressed such divergences of opinion and conception, so much patent misconception and so much lack of any conception as to warrant a review, together with a presentation of any additional information.

It is surprising to me how little attention has been called even to the fact of this confusion in proctologic literature, let alone to any attempts at elucidation. Probably the situation is in large measure explained by failure to recognize the full importance of the subject and its implications.

### IMPORTANCE OF THE TOPIC

Cases of total postoperative incontinence are an obvious concern, and yet there is lack of appreciation of three important facts in connection with these common unforgivable tragedies, viz that they are common, they are unforgivable and they are tragedies. The impressions obtained from descriptions that remedial plastic operations are easily accomplished is not true, for often it is difficult to secure a successful outcome.

More common are the cases of relative incontinence involving limited control, particularly regarding seepage of fluid or passage of gas. Social and business life may be thereby considerably restricted and the condition a daily burden, or at best a constant inconvenience. Not a little hesitation is encountered concerning rectal operations because of such cases among friends of prospective patients. The victims one meets—and they are by no means rare—have been rather firmly convinced by their surgeons that such sequelae are necessary and to be expected.

While it is true that in many cases relative and total incontinence are due to the vicious practice of postoperative packing, from my study they have been due

in the majority of instances to injudicious surgical practice based on ignorance of the surgical anatomy of the region.

Even more important from the standpoint of actual numbers of patients involved, the same factor is responsible for a large part of the inordinately high rate of recurrence following operations for fistulas. That is, righteous fear of injury to the sphincter mechanism and unfamiliarity with the applied surgical anatomy in relation to fistulectomy too often occasion a choice between unguided radical surgical measures with resulting degrees of incontinence, on the one hand, and timid measures with avoidable recurrences, on the other. In ignorance of what and where it is safe to cut, one avoids incontinence only to stumble far too frequently into the pitfall of a high recurrence rate.

Much of the fault for these far too common and unwarranted errors must be laid at the door of the proctologist, for while each proctologist has learned by exceptional experience the practical surgical anatomy adequate for his own use, his written formulations, on which others must depend for guidance, have in many respects proved inadequate and conflicting.

### REVIEW OF THE LITERATURE

As evidence of the confusion mentioned one can find expressed or implied the belief that usually none or but little of the external sphincter is involved in fistulectomy and, on the other hand, that the whole muscle or variable parts of it are concerned. Some authors have stated that fistulas may course "deep" to the internal sphincter, while others have not mentioned this possibility. Some have said that if the external sphincter is to be cut even partially the operation should be done in two stages and others that the entire muscle may be safely cut at one time or even a whole segment removed and still others have expressed opinions between these two extremes. One can find the belief expressed or implied that it is equally safe (or dangerous) to cut the external sphincter anywhere in its circumference, that it is safe to cut posteriorly, but not elsewhere, or both

Fig. 1—Schematic representations from the literature of anal anatomy and the relations of fistulas. They are common misconceptions and from them may arise erroneous implications as to (1) the simplicity of the clinical recognition of the external sphincter and (2) the common relation of fistulas to this whole muscle. Compare with figure 3.

posteriorly and anteriorly but not laterally, that cutting is only relatively safer posteriorly or that, owing to anomalies, posterior severance may on occasion be as disastrous as that undertaken elsewhere. One who believes that continence is chiefly dependent on the external sphincter can find support for his view in the literature, as can one who has the different impression that it is chiefly dependent on the internal sphincter, while recently the concept of the anorectal ring, a composite structure of parts of several muscles, as the guardian of continence has been developed. One

proctologist states that he has split the anal canal, including both sphincters and fibers of the levator, 600 times, while another counters that fistulas which necessitate such treatment are rarely seen even in a large experience, and that if the whole sphincter mechanism were cut even in stages, function would be definitely

Fig 2—Paraffin section of the wall of the anal canal. A levator ani muscle. B longitudinal muscular coat of bowel. C superficial and deep portions of the external sphincter. D mucosa. E internal sphincter. F anal intermuscular septum. G (small circle) subcutaneous portion of the external sphincter. The large circle represents the anorectal ring including portions of the internal sphincter, the longitudinal muscular coat, the levator ani and the deep portion of the external sphincter. Notice (1) that only the subcutaneous portion of the external sphincter is below and in the same longitudinal plane with the internal sphincter, the other two portions surrounding the latter. (2) the prolongations of the longitudinal coat of the bowel coursing through and thus dividing the external sphincter and (3) the continuity of structure between the levator ani and the deep portion of the external sphincter.

impaired. Postoperative packing rather than injudicious section is regarded by some as the essential element in the genesis of incontinence.

Possibly I have conferred undue importance on these differences, but from a critical analysis of fistula surgery in general it is obvious that something is lacking either in the facts available or in their adequate appreciation.

#### COMMENT

In almost none of the references, with the notable exception of the contribution of Milligan and Morgan<sup>1</sup> and an allusion by Hiller,<sup>2</sup> is there any discussion whatever or even a mention of the clinical recognition of the various component muscles mentioned. That is, amidst all these conflicting statements practically the only point on which there is apparently almost universal tacit agreement is the fundamental premise that the separate muscles can be easily, accurately and uniformly recognized at operation.

I am of the opinion that far from being so simple as to merit almost alone its undebated position this fundamental problem of clinical identification of muscles is responsible more than anything else for such divergent expressions. There exists gross error in this basic premise so universally taken for granted, in at least partial explanation for which I particularly point out here the inaccurate foundation of descriptive

anatomy commonly illustrated, but not described, in textbooks (compare figure 1 with figures 2, 3 and 4). Such simple relations depicted between the muscles and the simple and constant relation between fistulas and muscles do not exist, and the resultant clinical misinterpretations and erroneous assumptions are obvious as sources of confusion.

For clear analysis in accordance with conditions as they actually exist I point out that there are only two possible means of differentiating and recognizing these muscles clinically, viz by palpation and by sight (dissection).

Almost exclusive dependence must more often than not be placed on palpation, because operation involves commonly the limited exposure obtained with but a linear section, or little more, of the tissues. Thus this phase of the problem is of major importance.

I am in agreement with the recent observations of Milligan and Morgan as to what entities of the anal musculature can be recognized by palpation. For my purpose here these may be reduced to (1) the subcutaneous portion (only) of the external sphincter and (2) the anorectal ring (fig 2), a composite structure composed of portions of the internal sphincter, the longitudinal muscle fibers of the wall of the bowel, the levator ani and the deep portion of the external sphincter. In other words, it is impossible to distinguish by palpation the external and internal sphincters as complete distinct entities, it is useless therefore to say, as far as palpation is concerned, what can or cannot be done surgically with safety in terms of these muscles individually.

What further help is afforded by the sense of sight in recognizing the different structures discussed, and is it sufficient to compel alteration of this concept?

Fig 3—Paraffin section of the wall of the anal canal. A levator ani muscle. B external sphincter. C internal sphincter. D course of the fistula plotted as explained in the text, extending outward from the anal intermuscular septum and following one of the terminal prolongations of the longitudinal muscular coat through the external sphincter. The fistula involves here the subcutaneous portion of the external sphincter, the commonest arrangement. Occasional sections show as here and in contrast to figure 2, sharp demarcation between the levator ani and the external sphincter.

#### LABORATORY INVESTIGATION

Preliminary to answering this question I made numerous dissections in the autopsy room and studied gross and paraffin sections made in the laboratory. I

1 Milligan E T C and Morgan C N. Surgical Anatomy of the Anal Canal with Special Reference to Anorectal Fistulae. *Lancet* 2: 1130 (Nov. 24) and 1213 (Dec. 1) 1934.  
2 Hiller Robert I. The Anal Sphincter and the Pathogenesis of Anal Abscess and Fistula. *Surg. Gynec. & Obst.* 52: 921 (May) 1931.

shall not pause here for details of these different approaches but report compositely only the following salient points

It is impossible to define the internal sphincter as a clearcut anatomic entity because no upper border exists, the so-called internal sphincter being but the thickened lower border of the inner circular coat of the bowel. It would be comparable to determine where the handle of a baseball bat ends.

Fig. 4—Model of anal anatomy reconstructed in accordance with paraffin sections and including conceptions of Milligan and Morgan. A deep portion of the external sphincter. B superficial portion of the external sphincter. C subcutaneous portion of the external sphincter. D lower border of the internal sphincter. E region of anal intermuscular septum. F attachment of superficial portion of the external sphincter to the coccyx. Just lateral to D a piece of the subcutaneous portion of the external sphincter has been clipped off to show how the superficial portion of the external sphincter surrounds the internal only the subcutaneous portion being below and in the same longitudinal plane with the internal.

I have already referred to the complex relations of the external sphincter, as shown in the illustrations, and again call attention to their significance.

The external sphincter uniformly blends imperceptibly with the levator ani and tearing of the muscle is usually necessary to separation (except of course anteriorly, where the latter does not surround the anus).

From the several approaches I gained the distinct impression that pus extension could readily separate the external sphincter from the (encircled) internal sphincter to the upper border of the former but that, instead of breaking through here between the external sphincter and levator and thus completely separating the external sphincter, extension would more easily follow the strands of the longitudinal muscular coat of the bowel which course through the external sphincter (figs 2 and 3).

These facts from the laboratory not only corroborate the difficulties of palpation mentioned but also suggest difficulties in the accurate delineation of the muscles clinically even with the aid of dissection and sight, particularly, I repeat, with the little more than linear section warranted in most cases and with the interference of tissue planes due to inflammatory reaction and scar tissue. From them too one could with propriety question both the accuracy and the importance of discussions concerning operative trauma to the whole external sphincter because of the theoretically more ready involvement of but a variable part of that muscle.

I have not demonstrated to my satisfaction the separation between the superficial and deep portions of the external sphincter, as described by Milligan and Morgan, but this minor difference does not affect the usefulness of my concepts.

With this laboratory work as a background let me answer the question as to what of these structures I have been able to recognize clinically—and accurately.

#### CLINICAL OBSERVATIONS

In all my work with fistulas I have never found it necessary to identify the internal sphincter, nor am I certain that I could do so if I would, in the living human being, particularly in the presence of fistula scar tissue. As far as fistula surgery is concerned, reference to the internal sphincter as a clinical entity should be discontinued.

With cases involving wide dissection, such as those requiring plastic repair and a minority of fistulas more extensive or deeper than usual, I have delimited the external sphincter to my satisfaction. There are difficulties, however, such as accurately delineating it from the levator, as found in the autopsy room, but for the practical purposes of these operations I may say that the muscle can usually be defined. I emphasize, nevertheless, that considerable familiarity with the region may be necessary. Incidentally, my clinical experience bears out my theoretical deduction that involvement of the whole muscle is comparatively uncommon.

On the other hand, viewing as a whole the field of fistula surgery and considering the limitations of the dissection necessitated in the great majority of fistula operations and the difficulties imposed by erasure of tissue planes and the presence of scar tissue—all added

Fig. 5—The comparative effects of removal of short and of more extended fistulas on retraction of the ends of the sphincter. If the fistula extended but through the muscle A to B or a little more retraction would be limited as shown by the stippled area; if dissection included on the other hand such a distance as from B to C retraction with its bearing on subsequent incontinence would be more wide as indicated by the line shaded area.

to the anatomic complexities reviewed—one finds that the amount of muscular involvement in terms commonly used has been largely a matter of only approximate knowledge even to the expert. Considering further that the specialist still observes probably but

a small percentage of these cases, taken the country over, I suspect that, were the truth known, operation is done in a large proportion with no knowledge at all as to what muscle tissue is severed

I therefore reiterate the suggestion that the accepted concept of the surgical anatomy be rearranged to terms of (a) the subcutaneous portion of the external sphincter and (b) the anorectal ring, I believe this would obviate many of the difficulties outlined, from the standpoint both of the specialist and of the occasional operator. Recognition of these structures is simple of acquirement, its use is adequate for the purpose and particularly effective because by correct anal palpation (with the forefinger inside the anal canal opposed firmly to the thumb on the outside) one can both continuously follow tracts by their scar tissue and be constantly informed of their relations to the anatomic structures

Let me consider the question from a different point of view, by plotting the known directions pursued by fistulous tracts in relation to the planes of the anal canal and outside skin. This approach is a common one and becomes possible and valuable because for all practical purposes the internal opening of fistulas may be regarded as occurring at a fixed and constant point at or near the anal intermuscular septum. From here the most common course through the musculature is at right angles to the anal canal and thence in a gentle curve to the skin. Plotting this recognized course on the common misconception of anal anatomy shown in figure 1, an almost universal representation in the literature, gave theoretical basis to the assumption that the whole external sphincter was usually involved in fistulectomy, an assumption too easily accepted because of the unrecognized difficulties of adequate clinical recognition of the muscle herewith detailed. Plotting the same course on the correct anatomic conception, shown in figure 3, would involve in fistulectomy only a part of the external sphincter, which corresponds with the theoretical deductions mentioned earlier. Thus portions of the external sphincter, particularly the subcutaneous portion, have probably been often mistaken for the whole muscle, and in its clinical assumptions and applications proctologists have not all been talking about the same thing. The implications are obvious and support my previous conclusions

#### SUGGESTED RULES

Any formulation as to what is safe to cut should either make more accurate distinction as to severance in the different quadrants or, if in more general terms, provide adequate margin of safety to include all. It is not sufficient to say "Be a little more careful laterally than posteriorly." This too is the case in comparing short fistulas and those of wider extent, where more extensive dissection permits wider gaping of the severed ends of muscle (fig 5)

Recognition of the devastating effects of postoperative packing is a *sine qua non*, and all dictums regarding operations for fistulas must assume an understanding of this principle

Operative injury to the supportive framework of the anus outside the sphincters, injury to the nerve supply and atrophy of disuse are little discussed topics germane to my thesis which must forego consideration at this time

While the main object of my paper has been to point out and analyze the basic elements of confusion in the literature, for the sake of completeness I suggest, without time for discussion, the following rules in conformity with the anatomic concepts developed

1 It is always safe to cut once the subcutaneous portion of the external sphincter, in my opinion the portion most frequently involved

2 It is never safe (and exceedingly rarely necessary) to cut entirely through the anorectal ring

3 Amounts of muscle between that of the subcutaneous external sphincter and the anorectal ring can and should be cut by the two stage operation<sup>3</sup> (fig 6)

Fig 6—The principle of the two stage operation for rectal fistula. Dissection has been carried up to the sphincter musculature. Linen kordo is tied through the remaining portion around the muscle tissue involved. After the lateral wound has healed the remaining portion is severed usually in the office during local anesthesia. Wide retraction of the ends of muscle is thus obviated not only in accordance with the principles shown in figure 5 but because of the anchoring of the ends of muscle in scar tissue.

4 The attachment of the anus to the coccyx should not be severed at the primary operation

There will be dissenting voices, but I hope at least to have provided herein a more accurate basis for future discerning discussion. I do not maintain that even considerable variance is not possible, but any deviation must be determined by the individual operator according to and commensurate with his increasing familiarity and experience

#### ABSTRACT OF DISCUSSION

DR MALCOLM R. HILL, Los Angeles. I had occasion to observe this study and see it from a laboratory angle. I did not realize how incomplete an understanding of applied surgical anatomy I have been carrying in my armamentarium. The work of Hiller in this field has definitely explained that posterior proctotomy is not safe in 100 per cent of cases because of anomalies or muscle defects. Milligan and Morgan's work referred to by Dr Blaisdell, is fundamental. This conception of muscle relations has been upheld by such anatomic works as those by Cunningham and Spalteholz, but it falls to the lot of a modern anatomist-surgeon and more recently to that of a practicing proctologist to uncover these hidden facts in applied surgical anatomy of the anal sphincter mechanism. Previous application in part by Dr Blaisdell has given us a plausible explanation as to the cause of anal fissure. I refer to the published paper "Pathogenesis of Anal Fissure and Implications as to Treatment." Dr Tom E. Smith mentions this work in his article on "Anal and Perianal Fissures and Ulcers," maintaining that that obstructing portion of the subcutaneous external sphincter be

3 Allen J. Hill and Haisdell, Benjamin. A Two Stage Operation for Fistula in Ano. Surg. Gynec. & Obst. 38: 621 (March) 1934

called "Blaisdell's bar" I had the privilege of assisting in the operative amphitheater with the application of this conception of the surgical anatomy in cases of plastic repair following previous injury. It is valuable to proctology and surgery that Dr. Blaisdell should come to our rescue in thus scrapping the multiplicity of misinformed ideas and laying down certain fundamentals. We may thus be guided in dealing with complicated problems and be able to avoid injury to the anal sphincter mechanism.

## MEDICAL ASPECT OF CANCER OF THE STOMACH

SARA M. JORDAN, M.D.

BOSTON

Clinical research in malignant disease of the stomach, even though productive of no new or striking conclusions, is justifiable if it intensifies the impressiveness of certain facts which cannot be sufficiently emphasized if the disease is to be combated. This study of 251 cases, in 187 of which the lesion was considered operable, was undertaken in this spirit and particularly with the purpose of arriving at certain conclusions concerning the role of the gastro-enterologist, the general internist and the general practitioner in the treatment of gastric cancer. The surgeon's function is well defined and involves, in addition to surgical technique in a difficult operation, the decision as to operability and

Fig. 1—Prepyloric deformities suggestive of malignant disease but due to benign lesions. A, duodenal ulcer and prepyloric spasm. B, prepyloric ulcer and duodenal ulcer proved benign by gastroscopic examination and clinical course.

extent of operability when the lesion is actually visualized and palpated at the operating table. In some cases the surgeon has the first opportunity to detect early cancer of the stomach when operating for another lesion or to suspect it in his clinical contacts with a patient. Most frequently, however, the early diagnosis falls within the scope of the gastro-enterologist and the general practitioner and constitutes their chief duty in the treatment of this disease, a duty of more vital importance than their second one, that of postoperative care. The facts that cancer of the digestive tract occurs most frequently in the stomach and that its onset there is most insidious, together with the frequent perplexities of early detection and the value of early operation, make the first possible diagnosis of this disease a challenge to the acumen and vigilance of the general practitioner and the gastro-enterologist.

The history of gastric carcinoma is often definite. The stomach can be clearly visualized by x-ray examination, the chemical data are diagnostically suggestive

and the examining eye can now look at the lumen and mucosal lining with the gastroscope. There would therefore appear to be little justification for late diagnosis and the unhappy discovery of an inoperable lesion, but not infrequently, against the ideal of early diagnosis and early operation, certain conditions exist, chief among which are the apparent innocuousness of certain symptoms and an obscurity in the objective signs, particularly those of x-ray examination.

The first agenda of this study was to point out, not for the first time but in emphatic repetition, certain guiding signs which if followed might result in early diagnosis of gastric cancer. The questions asked and answered in part by these data concerned the role of the internist, for example:

- 1 In what type of patients does malignant disease of the stomach occur?
- 2 What are the earliest suggestive symptoms?
- 3 Are the diagnostic measures available today adequate for its early detection?
- 4 What good can be expected of early diagnosis and surgical intervention?

It is a usual medical mental procedure to suspect the ailing middle aged of cancer. The statistics of this series show that it should apply to gastric cancer, the largest number of patients, 68 per cent, being between 50 and 69 and almost equally divided between the 50's and the 60's. However, 19 per cent were in their 40's, 5 per cent were between 31 and 38 and 8 per cent were over 70. Sixty-three per cent were men and 37 per cent women in the group whose lesions were considered operable while in the group whose lesions were considered immediately inoperable 77 per cent were men and 23 per cent women. This variation in the two groups suggested the possibility that women seek aid somewhat earlier than men.

Translated into an answer to the question as to what type of persons may be suspected of gastric carcinoma, these statistics contribute the conclusion that all persons over 30, men twice as frequently as women, should be suspected of cancer of the stomach when certain symptoms are found.

The next question, what are the earliest suggestive symptoms? was studied through the statistics of this series. In most histories of cancer of the stomach, two stages are described, one preceding the other by weeks or months. The second may involve a change in the character of the primary symptoms, such as an intensification or a change in the time of occurrence of pain, or there may be a completely new group of symptoms. These two stages have been called primary and secondary in this study.

The same symptoms are found in different incidences in the two stages. Pain or distress, usually epigastric but in some cases described as general abdominal and in a few cases entirely atypical, for example in the right upper or left upper quadrant or in the shoulders occurred as the most frequent primary and secondary symptom. Loss of appetite and weight were the next most frequent primary symptoms and the third and fourth most common secondary symptoms. Nausea with vomiting was the second most frequent secondary symptom, and vomiting occurred as the fourth most frequent primary symptom. With lesions of the cardia hiccups and dysphagia occurred in a few cases as the primary symptom, and in a few cases constipation

or diarrhea alone was the primary symptom. Constipation was the fifth most frequent secondary symptom. The classic syndrome of loss of weight, appetite and strength thus maintains its importance as a strongly suggestive symptom of carcinoma of the stomach, but it is worthy of note that pain or distress, and in the secondary stage nausea and vomiting, were the commonest early symptoms. Since these are not insidious symptoms it should follow that, if they were properly evaluated by the patient and differentiated by the physician earlier malignant gastric lesions would be discovered. Possibly a useful rule for patient and physician might be that in a patient over 35 abdominal discomfort of over a few days' duration should be checked and if persistent rechecked with careful study, both roentgenographic and chemical. In not a few of the cases in which pain was the predominant symptom, it was attributed without x-ray or other study to ulcer and was treated as such, sometimes with temporary relief of symptoms and therefore delay in the final diagnosis. This study also brought out the fact that the earliest symptoms, especially when they were fatigue or loss of weight and strength, were too often treated as due to anemia or nervous exhaustion. Liver or iron therapy, long vacations and trips around the

world have sometimes been used as treatment when careful study should have been applied and reapplied. One of the lessons emphasized by this study was the value of rechecking, a procedure to which the public should be educated if cancer is to be diagnosed early.

To review, the two most frequent early symptoms of the disease are actually pain and nausea with vomiting, both of which are by no means insidious and are not diagnostic without differentiation. Loss of weight and appetite stood high in the list, the second most frequent primary and the third most frequent secondary symptom, and, though commonly recognized as the most important symptoms of cancer, were accepted by the patient and sometimes by the physician first consulted without adequate apprehension. A previous acute infection of the respiratory tract, a chronic prostatic or renal condition, and fatigue and worry were too often accepted as sufficient explanation. Two patients recently seen in the Laker Clinic had previously been sent for a winter in Florida and a world cruise, respectively, because of symptoms of fatigue and loss of weight, when they actually had an early carcinoma of the stomach, the growth being diagnosed months later and too late for surgical removal. Another patient's loss of weight and failing strength had been explained by himself and his physician by his inability to chew his food because of a new artificial denture until he

himself noticed an abdominal mass. Although neglect of symptoms as completely misleading as constipation, diarrhea or gaseous eructations is more to be condoned, this study emphasizes the importance of an examination of the entire digestive tract of the patient over 30 when any digestive symptom occurs.

The duration of symptoms before diagnosis was of considerable interest (table 2). In much the largest

TABLE 2—Duration of Symptoms Before Diagnosis

group, the patient came to the clinic either directly or very soon after his first consultation with his family physician, his symptoms having been tolerated by him without fear and without advice or because of that peculiar quirk of human mentality which causes man to fear to know that which is all the more fearful to know when he finally acknowledges it. The largest number of patients gave either six months or a year as the duration. Fifteen had had a long history of indigestion merging into the present symptoms, but it was a rather striking fact that in most cases the previous medical history was an unusually good one, the present illness being the first with many patients in their 50's or 60's.

The common finding of achlorhydria in the first examination is not devaluated by the fact that normal or high acidity occurred in thirty-two cases. There was achlorhydria in ninety cases, hypochlorhydria in twenty-nine cases, normal acidity in twenty-six cases and hyperchlorhydria in six cases. The presence of hydrochloric acid should make one no less suspicious, but its absence should increase suspicion. This is the only safe deduction from these statistics. Another important deduction made from a study of a few of these cases is that with a patient known to have chronic achlorhydria periodic check-ups of the stomach are indicated and certainly any new symptom requires

TABLE 3—Amount of Weight Lost

study. Furthermore, a change from normal or high acidity to achlorhydria in a patient under treatment for gastric ulcer or with a history of a healed lesion, or even without previous gastric disease, should arouse suspicion.

The amount of weight lost is indicated in table 3. One patient gained weight with ulcer treatment. The majority of patients had lost between 10 and 30 pounds before the diagnosis was made.

A palpable mass was noted in fifty-six cases. Resection was performed in twenty-nine of these (total in

three, exploratory laparotomy in seventeen, gastro-enterostomy in nine and gastrostomy in one. Of the twenty-nine patients who had resections, five lived from one to two years (three had metastases at operation), one, who had a total resection, lived three and one-half years (metastases were present at operation), one lived eight years (no metastases were present at opera-

careful fluoroscopic examination before and after relaxation management will usually distinguish adequately between phantom and actual lesions. In the occasional case exploratory operation must be done, and if a lesion is found at the pylorus it should be regarded as malignant and subtotal gastrectomy performed. In two cases of this series exploration was

done because an annular constriction persisted in the prepyloric area in spite of trial management, no organic lesion or adhesions were found to explain the constriction and, postoperatively over a period of years, occasional check-up examinations revealed the same type of deformity, which without the historical background would have again caused suspicion of malignancy. Spasm and adhesions in the media from a healing or healed ulcer of the posterior wall may also cause unwarranted suspicion, especially if no observation was made at the time of visualization of the ulcer or its healing progress. The appearance of the lesser curvature niche has aroused considerable interest among

FIG. 2—Benign lesions of the lesser curvature which might have been considered suggestive of malignant disease in *A* because of the meniscus surrounding the lesion and recurrence after subtotal gastrectomy; histologic examination indicating benign ulcer in *B* because of the irregular shape of the crater; disappearance of the crater during healing indicating a benign lesion; and in *C* because of the size and irregularity of the crater; histologic examination after subtotal gastrectomy done for recurrence indicating a benign lesion.

tion), and one has lived ten years (metastases were found at operation). These data add emphasis to the facts that a palpable mass is not a contraindication for surgical intervention and that small metastases are not a contraindication for resection.

X-ray examination has two purposes, diagnosis and location of the lesion and determination of operability. The modern technique of x-ray examination, particularly the recognition of the normal and abnormal mucosal pattern, determined by observing results with pressure palpation under the fluoroscope, and fixation of the picture with spot films, has been of great value in differentiating real from phantom lesions of the stomach and benign from the malignant lesions. The commonest phantom lesions simulating carcinoma are those caused by spasm, adhesions or loops of jejunum in close anatomic relationship to the pylorus. In spite of the medicinal and natural antispasmodics (such drugs as atropine and such natural measures as complete rest in bed and general relaxation), spasm of the two muscular apertures of the stomach, the cardia and pylorus, often persists to such a degree that visualization of the mucosal pattern in those areas and of the muscular activity and flexibility of the walls is impossible. This spasm has sometimes been found to be caused by disease elsewhere in the digestive tract or elsewhere in the body, as in a recent case in which autopsy showed that it was due to cardiac disease. Errors in diagnosis are then possible in either direction, ascribing the defect to spasm and not operating or ascribing it to cancer and operating uselessly.

Figures 1 to 4 are from cases in which differentiation between phantom or benign lesions and carcinoma had to be made, and figure 5 is from a case in which there was a ten year survival.

Endoscopic examination (esophagoscopy for the cardia and gastroscopy for the pylorus) is helpful and will be of more and more help in distinguishing spasm or other phantom lesions from organic lesions, except when the lesion is entirely submucosal. Then, however,

gastro-enterologists, and the statement has often been made and usually confirmed that irregularity of outline, broad base, lack of smooth contour and the presence of a meniscus around the base indicate a malignant process. Exceptions to this observation occurred in this study as figure 2 shows. Two patients of this series had had gastric ulcers which had been followed to healing several years previously. With one, opportunity was afforded by resection to find in the resected portion a carcinoma adjacent to the scar of the healed ulcer.

FIG. 3—Prepyloric deformities with histories suggesting malignant disease that shown in *A* was malignant while with that shown in *B* there was no organic lesion. The patient represented by *A* was a man aged 63 who complained of vomiting pain in the back (for seven months) and a loss of 9 pounds (4 kg.) in weight. The operative diagnosis was a small annular adenocarcinoma at the pylorus. The patient represented by *B* was a man aged 40 with nausea and vomiting of eight months duration and a loss of 30 pounds (13.6 kg.) in weight. The diagnosis was pylorospasm and nicotine poisoning.

The location of gastric lesions has long been regarded as of paramount importance in distinguishing the malignant from the benign. Malignant lesions occurred in this series in the cardia and fundus in thirty-one cases, in the media in fifty-two cases and in the antrum and pylorus in ninety-eight cases. Benign ulcers likewise occur in all these parts of the stomach. The only loca-

tion in which an ulcerating lesion is always malignant is the greater curvature, at any level, when exclusively involved. The prepyloric area has in recent years had more careful examination both at operation and at autopsy, and constantly increasing evidence accumulates to demonstrate the healed ulcer at this site, thus freeing this area from the gloomy verdict of inevitable malignancy.

Fig 4—A and B deformities of the antrum simulating neoplasm but produced by spasm following gastro-enterostomy. The patient represented by B had lost weight and strength for six months with an increased suspicion of malignant disease but the final diagnosis made by gastroscopic examination and the clinical course was gastritis and spasm produced by avitaminosis. C a malignant process in the antrum in a gastro-enterostomized stomach.

nancy. The fact remains, however, that in this series in 35 per cent of the cases in which resection was performed the malignant lesion was in the prepyloric antrum. Furthermore, progress in healing of an ulcer is not as easily or distinctly followed at this area as when the niche protrudes from the lesser curvature, and whenever, after a short period of trial management, doubt persists as to the flexible integrity of the stomach wall at this point, whether or not occult blood continues to appear in the stools and symptoms continue to be evident, subtotal gastrectomy is to be chosen as an alternative to the harbouring of an unhealed ulcer or a carcinoma. Benign ulcers at the cardia are rare, and most malignant lesions there are definitely irregular and rigid, their appearance leaving no doubt as to their malignancy. Furthermore the rare benign ulcer in this area can be observed to heal or not to heal especially with careful observation of the rugae the conformation of which around the lesion helps to make the diagnosis. If the lesion is malignant pressure, with a small amount of thick barium sulfate in the stomach, will reveal an irregularly distorted appearance of the rugae, which seem to disappear completely around the lesion, whereas with an ulcer the radiation of the rugae is more regular and intensified around the lesion.

The lesion of the media, if annular and constricting, may be a benign hourglass deformity of a healed ulcer or a malignant lesion infiltrating and constricting the stomach wall. Most of the latter type are clearcut rigid defects but the very early ones simulate the innocent hourglass defects of ulcer healing and can be distinguished only by their lack of flexibility, as observed by careful fluoroscopic examination.

The niche of the lesser curvature, usually in the media which whether large or small is so often the visualization of an ulcer represents occasionally a malignant lesion. In the most confusing cases, the healing or nonhealing can be observed by the disappearance of the niche or its persistence and if it persists resection is indicated because of actual or potential malignancy. The discrete smoothly outlined tumor of the stomach which from the x-ray examination might

be considered a benign leiomyoma, should in my opinion never be allowed to remain thus diagnosed, since except by histologic examination it is impossible to distinguish it from a malignant lesion, notably leiomyosarcoma.

Gastroscopic examination is of considerable help and, with further knowledge of the various types of gastritis, promises to be of still greater help in revealing early carcinoma, especially the ulcerating type, the typical ulcer being clear-cut and having sharp edges and a grayish exudate at the base and the typical ulcerating carcinoma having ill defined edges and a distorting of the mucosal pattern for some distance around the ulcer. Although the posterior wall and the pylorus frequently cannot be seen in cases in which this visualization is most needed to rule out the presence of a malignant lesion, observation of asymmetrical peristalsis, confirming the results of the fluoroscopic observation, is valuable as an adjuvant diagnostic sign.

The answer to the question Are present day diagnostic criteria of sufficient aid in making the diagnosis of cancer of the stomach adequate? is Yes, if they are used with precision and are applied and reapplied with constant vigilance.

The final question, What good can be expected of early diagnosis and surgical intervention? must now be confronted in the light of the data from this series.

Fig 5—The stomach of a man aged 63 who had survived for ten years cancer of the stomach with metastases to lymph nodes. In 1928 he had a six month history of epigastric distress and loss of weight (20 pounds 9 kg.). Subtotal gastrectomy was performed and the diagnosis was carcinoma of the pyloric end of the stomach with metastases to lymph nodes. In 1938 he was well and working though he required treatment for primary anemia.

(tables 4 and 5). If consideration of this matter is initiated with a reflection that gastric cancer is a grim disease and that survival of even a small group of patients for a year or more beyond the natural course of

the disease is a relatively successful result, detection and removal of the lesion is worth while. If the first recognition of trouble on the part of the patient could be synchronized to the actual beginning of the neoplasm, detection and removal would be decidedly more worth while. At present, detection appears to depend on the natural sensitivity of the patient to internal disturbance, the rapidity of growth of the lesion, the patient's mental attitude toward summoning help and the acumen and thoroughness of his medical consultant. The location of the lesion and its nature, whether ulcerating or

TABLE 4—Type of Operation

infiltrating, probably have considerable influence on the time relationship of the first symptom, but in this series no definite relationship could be established between location of the lesion and its early recognition. If obstruction at the cardia or pylorus occurs or an ulceration in the part of the stomach most involved in motility, the patient has an earlier consciousness of something wrong than if a part of the stomach less vitally concerned with its mechanics is involved, such as the posterior or anterior wall.

The statistics studied here show, unfortunately, no definite relationship of duration of symptoms and diagnosis of lesion to successful outcome, some of the patients who reported their symptoms earliest having died postoperatively after exploration only or removal of very advanced lesions. This fact would seem to frustrate the purpose of this study, which was intended to emphasize the importance of early diagnosis, but to offset the obvious inconsistency, it must be remembered that many potentially good results were thwarted by the necessity of submitting a patient in poor condition to a radical surgical procedure, whereas if the same patients could have had resection when they were in better condition, a large number would undoubtedly have survived. Furthermore, in the case of gastric cancer, with its natural 100 per cent mortality, even one patient in 187 who shows a ten year survival, with complete capacity for work, and several patients with a survival of from one to three years make worth while all efforts toward early detection and treatment.

The second part played by the internist in the treatment of gastric cancer is the management of the patient after resection. The late postoperative care of the subtotally or totally gastrectomized patient consists of encouragement during a long convalescence, practical aid in diet, maintenance of good colonic function, upkeep of nutrition and prevention of anemia. Convalescence is usually more protracted than after most surgical procedures, and this fact, together with the suspicion or knowledge by the patient that his lesion was malignant, usually makes psychotherapy, at least of the casual type, a real necessity. The diet is best

arranged in five small meals in order to avoid overdistention of the jejunum. The anastomosed loop of jejunum is found by fluoroscopic examination to distend moderately without discomfort to the patient and in the totally gastrectomized patient sometimes takes on the appearance of a small stomach. Overdistention, however, produces discomfort and sitophobia. The five meals should consist of the most easily digestible foods and be equal in size and of correct variety to supply all bodily needs. It is important to establish and maintain colonic tranquillity. The commonest form of colonic dysfunction after subtotal or total gastrectomy is diarrhea, and this is often controlled by the use of hydrochloric acid. Constipation is best treated by diet and the use of small rectal injections of oil or saline solution rather than by oral medication, as irritation of the colon may result in symptoms difficult to control and to explain to the apprehensive patient. Nutrition of the partially or totally gastrectomized patient is often maintained only with great difficulty, a fact which usually has no relationship to the nature of the disease, for it is equally true, according to my experience, after gastrectomy for ulcer. A woman in this series who had had total gastrectomy for carcinoma of the fundus had subsequent vomiting and substernal pain due to spasm at the anastomosis of the esophagus and jejunum, which was relieved by dilation of the esophagus, with resultant improvement in nutrition. Secondary anemia is a common sequela of the original disease and the operation and in most cases must be constantly combated. Anemia of the primary type requiring liver therapy occurred in a few cases of this series.

## SUMMARY

1 One should suspect cancer of the stomach in any patient over 30 complaining of any digestive symptom, but especially abdominal distress or loss of appetite and weight.

2 One should not send a tired middle-aged patient away for a rest or long holiday, even though his fatigue is adequately explained by circumstances, without

examining and reexamining him for cancer of the stomach, and one should not treat the "run down" middle-aged patient for anemia without a thorough study of his digestive tract.

3 One should follow the known achlorhydric patient and the patient with a known healed gastric ulcer with regular check-up examinations to be certain that no gastric malignant growth has occurred.

4 One should educate the patient to the idea of early and repeated examinations if unexplained symptoms persist.

5 In spite of well grounded pessimism regarding the average results in the present day treatment of gastric malignancy, one should regard each patient as an individual for whom the earliest possible diagnosis may result in the longest possible survival

#### ABSTRACT OF DISCUSSION

DR FELIX CUNHA, San Francisco With what Dr Jordan has presented here I am entirely in accord. The emphasizing of the early diagnosis of carcinoma of the stomach is, of course, continuous and insistent and incessant, and that is as it should be. Recently at the University of California there was a one week intensive seminar in gastrointestinal disease and forty-five physicians from the Pacific Coast showed enough interest to attend. Each day attention to early diagnosis of carcinoma was stressed in one way or another. I haven't any doubt that a patient falling into the hands of any of those men would stand a good chance so far as diagnosis of early carcinoma of the stomach is concerned. Gastro-enterologists must find a way to take a message to the physician who either lacks physical equipment to make diagnoses or practices medicine by trial and error. We have to take it to the man who is either temperamentally and intellectually unfit—I mean by that, either lazy or ignorant. He is the man who neglects the time element in arriving at a diagnosis. He diagnoses "indigestion," gives an alkaline powder and tells the patient to come back. The patient comes back unrelieved, and he gives him a different alkaline powder, and it is that interval of delay which seals the patient's fate so far as early diagnosis is concerned.

DR GEORGE M. UNDERWOOD, Dallas, Texas As I read only a few months ago some reports from Guy's Hospital which came out more than a year ago, it occurred to me that it might be interesting to this section to quote from them briefly at present in connection with this paper. In 1929 Dr A. F. Hurst suggested that chronic atrophic gastritis might predispose to carcinoma of the stomach. In America I think not a great many physicians thought much of the idea. I shall go back to the reports, which came out in 1936. The research commission from Guy's Hospital investigated a group of patients in the same economic class for oral sepsis, rapid eating, the eating of highly spiced food, the eating of very hot food and excessive smoking. Now, bearing in mind that the incidence of carcinoma of the stomach in the Netherlands is practically three times that in England, whereas the incidence of carcinoma in general is the same in the two countries, these things were found. Oral sepsis is one and a half times as frequent among the Netherlands, the eating of spiced food and the taking of very hot food, 60 C or hotter, is two and a half times as frequent among the Netherlands and the custom of eating exceedingly rapidly and the habit of smoking to marked excess are five times as great among the Netherlands. I think this emphasizes the conclusions that Dr Jordan made. It emphasizes that the medical man should be a source of education in his community. His influence should be toward studying the small lesion, the small benign ulcer, the small polyp and gastritis. Everything clinically possible should be done to prevent the development of these lesions, as they may later predispose to more serious lesions.

DR SARA M. JORDAN, Boston I thank Drs Cunha and Underwood for their discussions. There are two things more I should like to say about the study. 1 I felt it necessary, after studying the data, to follow the known achlorhydric patients by frequent x-ray examination because several patients with cancer of the stomach were known in previous years to have had achlorhydria. 2 I tried to make some correlation between the duration of symptoms and the operability of the lesion and, unfortunately, was not able to do so. This vitates, in a way, my theme which is a plea for early diagnosis, except that in each case it, of course, would have been an advantage to the individual subject to have an earlier diagnosis. Therefore if I may be a little facetious, the whole plea for early diagnosis is one for rugged individualism in the treatment of cancer of the stomach with a disregard for the average discouraging prognosis of the disease.

## FRACTURES OF THE LOWER END OF THE HUMERUS

GEORGE J. GARCEAU, M.D.

INDIANAPOLIS

It appears that physicians in general fear fractures of the lower end of the humerus. Many practitioners must treat these fractures in their communities. Often they ask the question "In what type of fractures about the elbow should I assume the full responsibility?" A knowledge of the prognosis would help them to select the fractures which are attended with the least danger. The treatment of supracondylar fractures is different from that of fractures of the lateral or medial condyle. This fact should also be of some help.

This paper, based on an analysis of 133 fractures involving the condylar region of the elbow, is an attempt to answer this question.

One hundred and seven or 80.5 per cent, of the 133 fractures were of the supracondylar and epiphyseal

Fig. 1 (case 1)—Supracondylar fracture of the left humerus

separation type. Fifteen, or 11.2 per cent, involved only the lateral condyle. Eleven, or 8.2 per cent, were fractures of the medial condyle.

#### SUPRACONDYLAR FRACTURE

The average age of patients with supracondylar fracture was 8.1 years. The youngest patient was 2 years old and the oldest 17. Eighty-four, or 78.5 per cent, were between the ages of 4 and 11 years. Ten were older than 13 years.

It is generally understood, and I thought correctly so, that if supracondylar fractures are fairly well reduced a satisfactory result will be obtained. I have compared the degree of reduction with the final result.

For comparison I have classified the reductions as shown by roentgenogram as excellent, good and fair. An anatomic restoration was called excellent. One with complete correction of the lateral or medial displacement of the lower fragment but with incomplete reduction as seen in the lateral plane was called good. Incomplete reduction in all angles was classified as fair.

In the supracondylar group, fifty-four reductions (50.5 per cent) were excellent. Of these, in 94.4 per cent there were excellent end results, and no unsatis-

From the Indiana University School of Medicine.  
Read before the Section on Orthopedic Surgery at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1936.

factory results occurred. In contrast, there were only 48.4 per cent excellent results in the group classified as good reductions. In the fair reductions there were only 9 per cent excellent results. This comparison would make one reflect on the statement that a fairly well reduced supracondylar fracture will give a satisfactory elbow. It is true that many elbows so treated

Fig. 2 (case 1)—Supracondylar fracture of the left humerus reduced by manipulation.

have excellent function but if deformity is present the result cannot be classified as excellent. Twenty-five of the 107 elbows had normal range of motion but had slight to very noticeable valgus or varus deformity after two years. These results have been classified as good or fair.

In the group of 107 cases the results were as follows: sixty-eight (63.5 per cent) excellent, twenty-four (22.4 per cent) good, twelve (11.2 per cent) fair and three (2.8 per cent) poor. Of the patients with poor results, one underwent amputation of the arm for gas gangrene with recovery, one had Volkmann's ischemic contracture and one has poor function with disability. Of the

Fig. 3 (case 1)—Excellent result. The line of fracture can be seen growing away from the elbow. There is a disturbance of the trochlear epiphysis.

twenty-five elbows with deformity, fourteen have visible angulation, eleven have valgus and three have varus deformity.

Seven of the twelve patients with fair results have limitation of motion and all have either valgus or varus deformity. Limitation of flexion will disappear with growth in cases in which the limitation is due to an anterior bone block at the lower end of the upper fragment.

Eight of the 107 patients required open operation owing to delayed reduction. Late open reduction is followed by slow restoration of function. The prognosis in supracondylar fracture of the humerus is good if early and accurate reduction is obtained.

The complications encountered were few. One patient had palsy of the radial nerve and recovered after neurolysis. One with palsy of the median nerve recovered spontaneously in about three months. Two elbows showed signs of ischemia. One was opened and the bicipital fascia was sectioned, resulting in excellent recovery. In the one which was treated without operation typical Volkmann's ischemic contracture developed. Myositis ossificans was not noted.

My plan of treatment is early reduction. Even when great swelling is present, reduction is attempted. Delay of three or four days makes reduction difficult, owing to induration of soft tissues and contracture of the triceps muscle and tendon.

The displacement of the lower fragment was backward, upward and often medial or lateral. In no instance in this series was the lower fragment displaced anteriorly.

Fig. 4 (case 2)—Fracture of the lateral condyle in a girl aged 11 years.

Under general anesthesia the laterally or medially displaced lower fragment is brought directly behind the shaft of the humerus. The elbow is extended and traction applied to the forearm. The elbow is then slowly flexed while both thumbs push downward and forward against the condyles, thus correcting the upward and backward displacement. The tendency is to correct incompletely the lateral displacement of the lower fragment. The arm is immobilized in a slightly padded posterior molded plaster splint, the elbow flexed from 45 to 70 degrees, and the forearm semipronated. The pronation relaxes the bicipital fascia. If the swelling is great, flexion of the elbow must be less. A roentgenogram is immediately taken, and if the reduction is not satisfactory the manipulation is repeated. Lateral or medial displacement of the lower fragment will result in valgus or varus deformity. Complete immobilization is maintained for at least three weeks. At the end of five weeks, support is discontinued. Heat massage and active motion are used but forceful passive motion is not employed. Physical therapy is not used extensively.

Volkmann's ischemic contracture is the most dreaded complication. A palpable radial pulse does not indicate

that ischemia is not impending. The contracture is due to the fibrosis of muscle tissue from anoxia. The venous obstruction may result from impingement of the lower end of the upper fragment onto the cubital veins, injury to the cubital veins, swelling or pressure from a hematoma under the antibrachial fascia. The venous return is blocked, resulting in the bursting of capil-

Fig. 5 (case 2)—Fracture of the lateral condyle treated by open reduction pinned with a beef bone peg.

laries in the muscle tissue. Pain, dusky blue discoloration, swelling, coldness of the hand, diminished tactile sense and diminished voluntary motion of the fingers are the danger signs. When these are present, flexion of the elbow should be decreased and, if improvement is not rapid, section of the bicipital fascia is indicated. Delay results in irreparable damage. Splintage may be a contributory cause but is seldom the primary cause of Volkmann's contracture. Early reduction, elevation of the arm or, if necessary, section of the bicipital fascia will lower the incidence of ischemic contracture.

#### FRACTURES OF THE MEDIAL CONDYLE

There were eleven fractures of the medial condyle, 82 per cent of the series. The ages ranged from 2 to 15 years and averaged 8.2 years. The displacement was mild in five cases and considerable in six. The results were excellent in 45.5 per cent, good in 45.5 per cent and poor in 9 per cent (one case). There were four open reductions with internal fixation, with end results classified as good. The patient with a poor result should have had internal fixation. One patient had palsy of the ulnar nerve at the first examination but recovered spontaneously in about six months. Medial condylar fractures with displacement should be opened and internal fixation of the fragment used.

#### FRACTURES OF THE LATERAL CONDYLE

Fractures of the lateral condyle offer a more formidable problem. Many excellent contributions have appeared on this subject, especially those of Speed and Macey<sup>1</sup> and Wilson.<sup>2</sup> Lateral condylar fracture with displacement is considered to indicate open reduction and internal fixation with a nail, bone or ivory peg.

There were fifteen (11.2 per cent) lateral condylar fractures in this group. The average age was 8.5 years. Six patients (40 per cent) with considerable displacement were treated by open reduction. Of these, two have excellent and four have good results. For nine with little displacement of fragments reduction by closed manipulation was used. Of these, two have excellent, three good, two fair and two poor results. The two patients with poor results have anterior displacement of the condyle with union. One patient with a functionally fair result has nonunion. The prognosis in fractures of a single condyle, even with open reduction and pinning, is not so favorable as in the supracondylar type. This type of fracture, as seen in the roentgenogram, does not appear as serious as the supracondylar fracture. No neural lesions were observed in this group.

Analysis of cases for epiphyseal disturbance revealed fourteen instances. The epiphyseal architecture at the lower end of the humerus is complicated. There are at least four important centers of ossification: the two epicondyles, that of the trochlea and the epiphysis of the capitellum. It is not surprising that the epiphyses are often involved in the so-called supracondylar and always in the single condylar fractures. The fourteen patients with cubitus valgus and varus had disturbance of growth. The deformity could not be entirely accounted for by displacement laterally or medially. The anteroposterior views demonstrated excellent reposition of the lower fragment. The deformity increased in two years. I believe this was due to arrested or delayed growth at the epiphysis.

#### SUMMARY

1. Supracondylar fractures of the elbow must be differentiated from single condylar fractures.

Fig. 6 (case 2)—Result excellent, no deformity being present after fifteen months.

2. Supracondylar fractures should be reduced accurately and early. Lateral or medial displacement of the lower fragment must be avoided to prevent deformity, especially when the epiphysis is involved.

3. Single condylar fractures with displacement are best treated by early open reduction and internal fixation.

4. Volkmann's ischemic contracture is due to obstruction to venous circulation in the forearm. Early reduction is the best prophylaxis.

#### ABSTRACT OF DISCUSSION

DR J. H. DORMAN, Dallas, Texas I believe that the reason better treatment for fractures is not had is that fractures as a subject are entitled to a place of their own and should be taught better. The student should be made to realize the importance of proper treatment in the first service rendered, as this is the all important service and must be rendered by the man on the ground. Such service can be rendered by the specialist only in a comparatively few instances.

DR H. W. SPIERS, Los Angeles Dr Garceau has presented an excellent review of his rather large series of fractures of the lower end of the humerus of children. His effort to answer the question of the general practitioner "In what type of fractures of the elbow joint should I assume full responsibility?" is a praiseworthy one. There are so many pitfalls to avoid in the successful care of fractures of the elbow in youth that one hesitates to be at all dogmatic. One thing seems certain. Excellent early reduction and maintenance of reduction will secure a good anatomic and functional end result. It might be well said "Call for help when reduction is difficult and not satisfactorily maintained." My experience coincides with that of Dr Garceau in that single condylar fractures with displacement require early open reduction and fixation. This is not always an easy procedure. With the capitellum it is sometimes almost impossible. Here in California the medicolegal problem in connection with fractures in children is a serious one. The statute of limitation for minors does not hold until the person has passed his twenty-second birthday. I should have liked to hear Dr Garceau say something about the difficulties of x-ray diagnosis of fractures about the elbow in childhood. Many of the problems of malunion that have been encountered are based on this diagnostic difficulty. It has been my routine to roentgenograph the opposite elbow for comparison when the condition is doubtful. The epiphyses about the elbow are numerous. Consolidation of these makes an ever changing picture. Fractures through the epiphyses and cartilage often are not readily apparent. The angle of the capitellum and the shaft changes as growth takes place. The foundation of Dr Garceau's entire summary is predicated on accurate x-ray diagnosis. To me this item seems tremendously important in assuming responsibility. The author has given the unvarnished end results of his experience. I am in agreement with them, however, I would suggest to the average general practitioner that he be fully awake to the load he must carry if he treats complicated fractures of the elbow of children.

DR J. ALBERT KEY, St. Louis I do not know why Dr Garceau did not include fractures of the epicondyle of the humerus with the fragment displaced into the elbow joint. In cases I have observed it has been necessary to open the joint, get that fragment out and fix it back in place. Dr Garceau made the statement that Volkmann's ischemic contracture is due to venous obstruction, and that has been the general opinion since Barney Brooks reported his experimental work in which he tied off the veins to the gastrocnemius muscle in the dog. A month ago I opened the forearm of a boy 10 years old who had had a supracondylar fracture previously and who had a perfect anatomic reduction with immobilization in acute flexion. When I saw him three weeks later he had complete paralysis of his median and ulnar nerves and typical Volkmann's ischemic contracture. I performed neurolysis of these nerves from the wrist to a point above the elbow, and the muscles looked like the white meat of a chicken. The amazing thing to me was the relatively slight bleeding. I was delayed considerably in my operation by attempting to preserve the radial and ulnar arteries. I started from the bottom because it seemed to me that that was the easiest place

to find these nerves. By the time I got up to the elbow I began looking for the brachial artery and I could not find it. It was not until that dissection was carried 3 inches above the elbow that I was able to get a pulsating brachial artery. In other words, this Volkmann's paralysis occurred in the presence of total occlusion of the artery and not of the veins. It was stated that the hand had not been noticeably swollen at any time.

DR HUGH T. JONES, Los Angeles Another word about Volkmann's ischemic contracture. Not long ago I was called to see a child who on a Sunday night had sustained a fracture of the elbow. The general practitioner in charge had watched the arm until Wednesday night. There had been a radial pulse. Wednesday night. Thursday morning, very early, it was absent. I saw the patient about 5 a. m. I reduced the fracture, using Kirschner wires. There were signs of paralysis of the median nerve. Neurolysis was done. I also tried to expose the brachial artery. I had trouble too in finding it, but cut the fascia of the biceps and was sure that I had relieved all pressure about this artery. Still there was no return of the radial pulse. It worried me a great deal. I closed the wound. In the course of the morning a positive and negative pressure apparatus was used without help. In the afternoon the child still did not have a radial pulse. The stitches were taken out of the skin of the wound, and immediately the radial pulse came back. It happened that the skin had stretched to its elastic limits and was acting as a tourniquet about that arm, because the second that I took those stitches out of the skin the radial pulse returned. So I am sure along with Dr Key, that I had encountered a case in which the brachial artery was at fault instead of the vein.

DR STEIFF F. STEWART, Los Angeles I want to stress again the points concerning Volkmann's ischemic contracture. First, I feel that in case of a rapidly swelling forearm fascial decompression should be done at the earliest possible moment, second I agree with Dr Key as to the importance of the brachial artery and wish to record one case in which Volkmann's ischemic contracture followed a compound fracture and division of the brachial artery in the midarm.

DR GEORGE J. GARCEAU, Indianapolis Difficulty is often encountered in obtaining satisfactory anteroposterior roentgenograms, which are necessary in order to estimate the degree of reduction. I often take roentgenograms of the opposite elbow for comparison. Drs. Key, Jones and Stewart believe that injury to the artery may cause Volkmann's contracture. I agree with that opinion. It is my belief that the contracture is the result of anoxia and, of course, arterial occlusion will cause anoxia. The artery may be injured by the lower end of the upper fragment. It may be torn. I have opened such forearms and found the muscles full of bloody exudate. In one such case the artery was patent. I doubt very much that splintage is a primary cause of Volkmann's contracture. I believe that the original injury is the cause and not the method of treatment.

**Prevention of Malaria in Italian Troops**—In the recent war in Ethiopia malaria did not give very serious concern, although on the northern front a number of zones were badly malarial and on the southern front all the zones were terribly malarial, the disease being absolutely general among the indigenous Somali population. With a white army approximating half a million men there were 1,241 cases of primary malaria admitted to hospital and 1,093 admissions for relapses, with twenty-three deaths from pernicious forms, including black water fever, which was extremely rare. What were the prophylactic measures taken? With the troops continuously on the move and the area of operations being enormously extended mosquito nets and antilarval measures were often impossible. From the beginning we insisted on quinine prophylaxis every soldier received three tablets a day of quinine sulfate or bichlorohydrate, each tablet containing 0.2 Gm (3 grains). The men also knew that we could find out whether they had taken quinine or not. They were frequently paraded and one in every ten or twenty men was made to pass urine. This was tested with Tanret's reagent on adding a few drops of this reagent, if quinine has been taken, the urine becomes turbid, if quinine has not been taken the urine remains clear—Castellani, Sir Aldo. *J. Roy. Nat. Med. Serv.* 24:304 (Oct) 1938.

## Clinical Notes, Suggestions and New Instruments

### LOSS OF SUBCUTANEOUS FAT OF THE LOWER EXTREMITIES (LIPODYSTROPHY)

JOHN A. BIGLER, M.D., CHICAGO

Lipodystrophy is a disorder in which there is a loss of subcutaneous fat. The loss is absolute in that in the affected areas there is a complete absence of the subcutaneous tissue fat. None of the other tissues seem to be involved. The face is affected most commonly and more markedly than other parts of the body. The absence of fat is not congenital, because in affected persons the fat has previously been present in the regions from which it disappears. In some reported cases there has been an apparent increase in the fat of the lower part of the body. The condition is undoubtedly a disease entity rather than a symptom complex because of the absence of any other clinical, physical or pathologic manifestations. In association with other diseases there may be a marked decrease in the amount of subcutaneous fat but the fat loss is never absolute. The disorder is not familial, and there is no impairment of the health. The onset usually occurs from the fourth to the eighth year of age. The case here reported is unique in that, while there is the typical loss of subcutaneous fat, only the lower legs are affected, the face and upper parts of the body being normal. I have been unable to find any record in the literature of a similar case.

N. M., an Italian girl born Sept. 23, 1923, was first seen in the Children's Memorial Hospital outpatient department Sept. 13, 1935. The only complaint was of underweight. There had apparently been normal development and nutrition until the age of 8 years. Since then there had been a progressing thinness, this being most marked in the lower extremities. The mother said that because the family was very poor the child did not get enough to eat. There was no loss of appetite. The birth was normal. There was a history of chickenpox at the age of 2 years, mumps at the age of 3 years and measles at the age of 5 years. There had been no illness near the time the loss of weight was first noticed. Three sisters and two brothers all older than the patient were apparently normal. The mother and father were living and well.

Physical examination revealed that the child was very thin, she was 56 inches (142 cm) tall and weighed only 59 pounds (27 Kg). The lower extremities appeared emaciated in contrast to the degree of malnutrition of the rest of the body. The skin was of normal color and was soft and elastic everywhere. Over the lower part of the legs it was extremely thin as compared with that of the rest of the body, although marked malnutrition was present. The reflexes were normal, as was the muscular power. Cutaneous sensation was normal. The veins and muscles were easily visible through the thin skin of the lower part of the legs. The examination was otherwise normal. The child was active and not physically handicapped.

The basal metabolism rate was plus 11. The intelligence quotient was rated as 77 per cent. The red blood cells numbered 5,440,000 and the white blood cells 7,600 per cubic millimeter. The differential count showed 50 per cent polymorphonuclears, 27 per cent lymphocytes, 16 per cent monocytes, 6 per cent eosinophils and 1 per cent basophils. The Wassermann and Kahn reactions of the blood were negative. The Pirquet, Schick and Dick reactions were negative.

A section of skin taken down to the muscle fascia from the calf of the left leg appeared normal except for a complete absence of fat. A section taken from the area above the left knee where the skin shows an abrupt change in its thickness was normal grossly and the fat was of the usual yellow color. The fat varied from 1.5 to 0.5 cm in thickness. On microscopic examination the section of skin from the calf revealed a complete absence of fat in the skin and subcutaneous tissue. The hair follicles contained a small amount of fat staining material. Where the subcutaneous fat should have been there were a few layers of a loose fibrous network. In every other respect the

sections were normal. In the sections taken from the thigh the skin appeared normal, as did the fat layer. The fat stained normally, and the fat cells were of the usual size. No changes could be seen to account for the decrease in the subcutaneous fat, although these sections were taken from an area which had partially undergone loss of fat. The microscopic diagnosis was complete loss of subcutaneous fat.

After more food was furnished to the family the child's weight increased to 67½ pounds (30.5 Kg) and the height to 57 inches (145 cm) in five months. The contrast between the nutrition of the lower legs and that of the rest of the body was more marked than previously. After the child had spent one year at a farm school, the weight increased to 90 pounds (41 Kg) and the height to 61.2 inches (155 cm). At this time the child was well nourished, even plump, down to the lower third of the thighs. From there down the lower legs still appeared emaciated, as did the feet.

Patient weighing 90 pounds (41 kg) and 61 inches (155 cm) in height. Note the extreme thinness of the lower legs as compared with the rest of body.

The gradation from the normally thick to the thin skin takes place rather sharply above the knees. Curiously, there is a small area anteriorly below the knees on both legs where the skin is of nearly normal thickness. The affected skin feels normal except for the loss of fat. Because of the thinness of the skin the veins are prominent and the muscles stand out. Menstruation has not begun but the breasts are moderately developed and the other prepubertal changes are present. There is no muscular weakness, and except for the loss of subcutaneous fat the child is healthy and normal. The illustration shows her as she appears now with the well marked contrast between the lower legs and the rest of the body.

Lipodystrophy is not an uncommon disease. Approximately 100 cases have been reported and undoubtedly many more have been observed. The skin of the face, neck, and thorax is most commonly affected but there may be extension to involve the scalp and arms and the trunk down to the iliac crests. Twelve cases in which there was involvement of the skin of the face, neck, and even the thorax have been observed at the Children's Memorial Hospital.

It seems that only rarely does the loss of subcutaneous fat extend from above to include the thighs because only three such cases have been reported. Watson and his associates<sup>1</sup> had a 38 year old patient with involvement of the face, neck and trunk and the thighs down to the tibial tuberosities. There was thought to be extra fat below the knees. In Christiansen's<sup>2</sup> 40 year old patient the loss of fat involved the face, upper part of the arms, trunk and thighs. Microscopic sections of the skin of the arm and thigh revealed a complete absence of fat. A boy 14 years old with involvement of the whole trunk and the upper part of the thighs was observed by Leipoldt.<sup>3</sup> In a case reported by Gilchrist<sup>4</sup> there was a loss of subcutaneous fat in various-sized localized areas of the legs. This case was not typical of lipodystrophy in that there was evidence of some peculiar type of infectious process.

The etiology of the loss of subcutaneous fat is unknown. Postmortem studies and tests of the body chemistry, including both fat and carbohydrate metabolism have all given negative results in such cases. The following theories have been advanced to explain the loss of fat: 1 There is a local disturbance in the subcutaneous tissue interfering with the normal disposition of fat but in these cases fat is actually absorbed. 2 There is a dysfunction of one or more of the endocrine glands. When glandular dysfunctions are present there is usually an increased deposit of fat rather than complete loss of fat. Also if the loss is on an endocrine basis there is no reason why it should always be localized and never general in distribution. 3 There is a disturbance of the trophic nerve mechanism having to do with fat distribution and metabolism. It has been suggested that there may be a center in the midbrain in the region of the floor of the third ventricle for the control of fat metabolism and distribution. If such a center exists it is peculiar that in all the cases of lipodystrophy so far reported the loss of fat extended from the upper portion of the body downward and that in no case was it generalized. One may reasonably ask why involvement of the lower extremities alone is so rare.

Lipodystrophy is easily differentiated from cachexia in that the latter condition is of general distribution and although there is a decrease in subcutaneous fat the fat is never completely absent. No form of therapy is known which is of benefit in the case of lipodystrophy.

## RUPTURED TUBAL PREGNANCY

A HELPFUL DIAGNOSTIC SIGN

LEO BRADY, M.D. BALTIMORE

Almost twenty years ago T. S. Cullen<sup>1</sup> drew attention to bluish discoloration of the umbilicus as a sign of ruptured extra-uterine pregnancy and even though this sign is shown by only a small percentage of the patients with tubal gestation nevertheless quite a large number of cases showing bluish discoloration of the umbilicus have been now observed and reported. Hence I would hesitate to increase the already large number of reports of such cases were it not that a patient whom I recently had under my care showed a Cullen sign which differed from the majority of the cases already reported in that the discoloration of the skin and subcutaneous tissue did not appear at or around the umbilicus or in a postoperative hernia but in a thin spot in the abdominal wall which had developed as the result of an operation for a ruptured appendix. A careful study of the literature revealed that only two such cases have been previously reported, one in 1932 by Schmitz<sup>2</sup> and the second in 1935 by Smith and Wright.<sup>3</sup>

<sup>3</sup> Smith Irwin and Wright F. J. *Cullen's Sign in Ruptured Ectopic Gestation* Lancet. 1: 930 (April 20) 1935.

A summary of my case is as follows: Mrs. A. S., aged 35, was admitted to the Johns Hopkins Hospital April 17, 1938, complaining of pain in the lower abdomen and irregular uterine bleeding. She had been operated on for a ruptured appendix in 1923. The rest of her past history was unimportant. Up until the time of the present illness the menstrual periods had come regularly and had lasted four days, and there had been no bleeding between the periods. The patient had never suffered from dysmenorrhea. The March menstrual period, which was due on the thirteenth, did not start until the twenty-fourth but when the patient did commence to bleed she continued to do so until she was admitted to the hospital three weeks later. During these three weeks she had recurring attacks of sharp pain in the lower part of the abdomen. There had been pain on defecation but no dysuria. There was no history of weakness or fainting spells.

The patient volunteered the information that one week before she entered the hospital that is about two weeks after the onset of the irregular bleeding she had noticed that the old operative scar had turned bluish black. She added that the bluish black in the scar had been gradually getting less between the time she first noticed it and the time she entered the hospital.

Cullen sign appearing in a postoperative scar in a case of ruptured tubal pregnancy. The color is most intense in the center of the scar and fades out in the tissues around the scar. The umbilicus is normal.

On admission to the ward the patient did not appear to be in shock. Her temperature was 98.6 F and her pulse rate 80 to the minute. The hemoglobin was 84 per cent and the leukocyte count 9000. The breasts showed colostrum. The abdomen was not distended and the respiratory movements were free. The right lower quadrant of the abdomen presented a remarkable appearance. The center of the postoperative scar was bluish black, while the surrounding area showed different hues of color, such as are seen in a fading bruise. The umbilicus itself was normal in appearance. There was no hernia in the postoperative scar but the abdominal wall was thin in this region. There was definite tenderness on palpation over the lower part of the abdomen.

On vaginal examination the cervix was soft. The body of the uterus was forward and slightly enlarged. There was marked tenderness on pelvic examination and in the left fornix a soft sausage shaped mass could be felt. A diagnosis of a ruptured left tubal pregnancy was made.

The drawing shows the appearance of the abdomen before operation. The bluish black discoloration of the scar made me feel confident that my diagnosis of ruptured tubal pregnancy was correct, even though I was aware that occasionally other conditions, such as bleeding from an ovary, may cause intra abdominal hemorrhage and thus may produce a Cullen sign.

At operation about 200 cc of old blood was found in the pelvis. The omentum was adherent along the old operative scar. The left tube was the site of an ectopic pregnancy. The rupture had occurred in the tube near its distal end. The left fallopian tube was removed. The patient's convalescence was uncomplicated and she was discharged on the sixteenth day after operation. While the patient was in the hospital the bluish black discoloration in the old scar gradually lessened, but it was still apparent when she was discharged and did not disappear until the patient had been home about two weeks.

#### SUMMARY

In a case in which the typical bluish black discoloration of the skin and subcutaneous tissue first described by Cullen as indicating intraperitoneal hemorrhage was seen the discoloration occurred in a weak spot in a right rectus scar and not at the umbilicus. There was no postoperative hernia. It would seem therefore, that in cases in which intra-abdominal hemorrhage is suspected the Cullen sign should be looked for not only at the umbilicus but also in any weak spots in the abdominal wall such as sometimes result from abdominal operations even when there is no hernia present.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS  
HOWARD A. CARTER, Secretary

### ALLERGIA PILLOWS AND MATTRESSES ACCEPTABLE

Manufacturer: Allergia Products Company, 99 Chapel Street, Newton, Mass.

Allergia Pillows and Mattresses are recommended to give relief from allergic disturbances which are caused or aggravated by the irritation of dust generated by normally used bedding fillers. It is claimed that Allergia Products Company employs a pure silk fiber which has the inherent property of not breaking down into dust so readily as do commonly employed filler materials. The filler is encased within a diastaford woven tick, the latter having been processed to render it normally free of sizing dust and starch which are generally considered to be allergic irritants.

An Allergia mattress is made in much the same way as any other mattress but differs in the respect that any materials which may offer an allergic disturbance have been omitted and materials which are known to be relatively free from irritating dust are used in their place. These mattresses are made with an inner spring unit which is covered with deep layers of filling material both top and bottom.

The firm claims, further, that its products provide relief in approximately 98 per cent of the cases in which the individual is sensitive to house dust. In this connection the firm states that it is mindful of the fact that of all allergic persons who are sensitive to house dust there are approximately 2 per cent who are allergic to silk. The firm believes that those who are sensitive to silk are sensitive to it in some other form than that used in Allergia filling material. For example, those who might be sensitive to a cutaneous contact with silk would not be apt to be sensitive to it within a pillow ticking.

To support the claim that the pure silk fiber used in Allergia products has the inherent property of not breaking down into dust so readily as do the other commonly used filling materials the firm submitted a box of Allergia filling material which had been in use in a mattress for over two years. This was referred along with the pillow and mattress to a qualified investigator appointed by the Council. The following report on the product was submitted:

Saline extracts were made from the new material and from that which had been in use in a pillow for two years in accordance with the usual technique employed in making house dust

extracts. This consists of placing a handful of the material in a pint jar and wetting it thoroughly with physiologic solution of sodium chloride containing 0.4 per cent phenol. Sufficient additional fluid is added so that the jar will be filled about one-eighth inch above the soaked material. The surface is covered with toluene, the jar is covered and the extraction is allowed to proceed for twenty-four hours. The saline extract is then squeezed out and is filtered through a Seitz filter. In this way a solution of the active material, as nearly saturated as possible, is obtained. This material is used intradermally, undiluted.

Five extremely house dust sensitive allergic persons were tested with extracts from both of the materials referred to and it was found that, whereas there were no reactions to the new material, relatively large and significant reactions were obtained to the extract of the material which had been used for two years with four of the allergic persons.

Since it was desirable to eliminate any error due to some irritating material which might be present in the used sample, both extracts were then dialyzed against distilled water for forty-eight hours. The salt content was then brought up to 0.85 per cent and further tests were made on the same five patients with the same result. Good reactions were not obtained with other patients given very small or indifferent tests to house dust and, while some of the active material which is called house dust is formed in the Allergia material, it is present in much less concentration than in a cotton mattress or pillow in use for the same length of time.

It is worth while to state that there is no such thing as a nonallergic substance. There can be only substances which are less likely to be the cause of sensitivity than others. The Allergia pillows and mattresses seem to belong to the latter category.

As a practical measure any bed may be rendered efficient and satisfactory for the house dust sensitive patient by completely encasing the mattress and pillows in any impervious material.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Allergia Pillows and Mattresses for inclusion in its list of accepted devices.

### MEDICOPASTE BANDAGE ACCEPTABLE

Manufacturer: Medicosane Laboratories, 1472 Broadway, New York

Medicopaste Bandage is an adhesive gauze bandage impregnated with zinc oxide paste (Unna's boot). The bandage proper is wrapped in four layers of wax paper and placed in an airtight can. It is a 4 inch bandage available in 7 or 10 yard lengths. The active ingredients include zinc oxide, glycerin and 0.1 per cent each of phenol (carbolic acid) and formaldehyde as preservatives. The melting point of the medicinal paste is lowered so that it stays liquid at usual room temperatures and needs no heating. Thus the wet bandage may be applied in the form of an Unna boot without heating or painting. It is white.

The company recommends it as a means of applying a firm yet resilient compression dressing or mechanical support which will not yield to the expansion pressure of swelling. It aids the circulation by applying an even continuous pressure. In addition, it is claimed that the paste stimulates healing and is nonirritating to the skin.

Principal indications for its use, according to the firm, are vascular inflamed varicose veins, thrombophlebitis, ulcers, swellings, postfractures, foot ailments and eczemas. Other possibilities of use include sprains, prophylactic dressings in threatened thrombophlebitis, dressings on other parts of the body and in unpadded plaster of Paris casts as an intermediate layer between the skin and the cast. This product was examined and tried in clinical practice and found useful for the treatment of thrombophlebitis and ulcers and apparently fulfils the requirements of a firm elastic resilient support.

In view of the foregoing report the Council on Physical Therapy voted to include the Medicopaste Gauze Bandage in its list of accepted devices.

## THE AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

Reports received on the American Medical Association Study of Need and Supply of Medical Care already cover a far larger sample of the population than has been covered by any previous survey. This is the first survey that has asked and obtained information from all groups in the population definitely interested in medical care. Many who should know better still repeat the falsehood that this survey requests information from physicians only and insinuate that doctors know nothing about those who do not come to the physician's office.

Only one of the nine forms used in this survey is directed to physicians and dentists. The others are sent to hospitals, nurses, health departments, welfare and relief agencies, schools both public and parochial, colleges and universities, fraternal and similar organizations, and pharmacists. All these are asked for information concerning persons unable to obtain needed and desired medical care. Not one significant source of first hand, reliable information as to medical conditions has been omitted.

The returns from the eight forms sent to others than physicians are uniformly much more complete than those from the physicians and dentists. It is not at all uncommon for a county medical society to receive 100 per cent replies from these institutions and individuals, while no such percentage of returns has ever been obtained from physicians and dentists.

However much generalized discussion and disagreement there may have been between representatives of some of these institutions and the medical profession as to the extent of medical care, individual managers of hospitals, welfare organizations and similar bodies when asked to report definitely and specifically regarding the conditions with which they are personally familiar agree to a remarkable extent with physicians. In no report so far received has there been any sharp disagreement as to need for additional medical services where such exists and as to the absence of such need in localities where adequate provision of medical care now exists.

The most general lack of medical care that is reported is with regard to insufficient appropriations for poor relief or governmental institutions. The impression is gained from a reading of the reports—which have not as yet been tabulated to make such a conclusion absolutely certain—that the most important obstacles in the way of those who need medical care are the red tape and official regulations which restrict the giving of medical care.

Another striking observation is the large number of counties in which all sources of information agree that no one in the locality who desires and seeks medical care is denied it. The road to such care may be obstructed by the red tape and regulations already mentioned, and there is need to clear away these obstacles but there is no locality in which any organization even suggests that "one third of the population" is unable to obtain medical service.

## BRONCHIECTASIS

The essential abnormality in bronchiectasis according to Kline,<sup>1</sup> is the absence, atrophy, damage or destruction of elastic and muscular tissues of the bronchial wall. Usually severe inflammation of the various coats occurs first with damage or destruction of the elastic and muscular tissues. Finally there is complete destruction of a portion or all of the bronchial wall, associated with inflammatory and chronic changes of the regional pulmonary parenchyma. In children staphylococci, in adults the Miller-Vincent micro-organisms are frequently the causative agents responsible for the necrotizing changes. Cylindric, fusiform or saccular bronchiectasis develops, depending on the location, extent and severity of the process.

Bloch and Francis<sup>2</sup> differentiate primary or predisposing factors in the etiology and secondary or immediate agents. The primary factors consist largely of acute infectious diseases involving the upper respiratory tract. Among the secondary causes involvement of the nasal sinuses, chiefly the maxillary, is increasingly recognized as having a dominant part in the origin of bronchiectasis. Bronchiectasis, these writers say, is essentially a disease of the lower lobes of the lung which are most easily accessible to drainage from above. One or both lower lobes were involved in fifty-four of sixty patients. Of single lobes, the left lower one is the most frequently affected.

Since the use of iodized oil for bronchography according to Singer,<sup>3</sup> the positive diagnosis of bronchiectasis can be made even to its character. Following the instillation of the oil, the film would be expected to show the tubes widened, beaded, cylindric or cystic when an atelectatic bronchiectatic area is present. The compensatory lung fields are seen with bronchi wide

1 Kline B S Pathology of Chronic Nontuberculous Inflammations of the Lung Am Rev Tuberc 38 663 (Dec) 1938  
2 Bloch R G and Francis B F Chronic Nontuberculous Infections of the Lung Am Rev Tuberc 38 651 (Dec) 1938  
3 Singer J J The Roentgenological Aspects of Nontuberculous Pulmonary Disease Am Rev Tuberc 38 680 (Dec) 1938

apart and not dilated. A case of bronchiectasis should not be considered as completely examined roentgenologically until both lungs have been injected. This is particularly important since the medical treatment in most cases is at best only palliative. Bronchoscopy, according to Samson,<sup>4</sup> is also important as a procedure for the diagnosis and treatment of certain pulmonary infections. In bronchiectasis, bronchoscopy usually reveals diffuse dull red mucosal inflammation. There is moderate granulation and ease of bleeding, both observations increasing in intensity as the pathologic lobe is approached. Samson states further that bronchoscopy, while not curative of bronchiectasis, may produce an amelioration of symptoms, in fact, cough and sputum may disappear for years following a series of bronchoscopic aspirations.

Most therapy with the exception of lobectomy in selected cases has proved disappointing. Lobectomy, however, carries definite risks and requires as indication, in the opinion of Bloch and Francis, a unilateral or practically unilateral involvement. One stage lobectomy for bronchiectasis is approved also by Brunn and Goldman<sup>5</sup> based on extensive experience.

The prevention of bronchiectasis has been sadly neglected up to now. There is much parental negligence of chronic upper respiratory infection and chronic bronchitis in children. Bloch and Francis emphasize the danger of slow and continuous flow of infected material into the bronchial passages in the production of bronchitis. They believe that as the growing recognition of the role assumed by chronic sinusitis in this disease increases the occurrence of bronchiectasis should decrease. From a climatic point of view they believe that bronchitis of minor degree is favorably influenced by that atmospheric dryness which is beneficial for sinusitis. However, it seems to them that a permanent change of domicile in most instances alone can yield lasting results.

#### TRAUMATIC FAT NECROSIS OF THE BREAST

Traumatized or ischemic fat in any part of the body can undergo sterile autolysis or heterolysis resulting in saponification by histiocytes and giant cells. Shattock in 1896 gave an accurate description of the changes found in his case of 'saponifying necrosis in a lipoma of the thigh'. Fat necrosis has occurred in the subcutaneous tissues of young infants (Farr) in a hernial sac the thigh, the buttock or the abdominal fat. These lesions are harmless and of little clinical importance. When fat necrosis occurs in the cellulose-adipose tissues over the breast or in the breast, however, the lesion assumes a special clinical significance principally because it mimics so closely the clinical signs of mammary cancer. The knowledge of this lesion dates from a report in

1920 of two cases by Lee and Adair.<sup>1</sup> In one of these cases a radical amputation of the breast, muscles and axillary contents was performed because the surgeon believed that the tumor was malignant. In the other, the possibility of a benign lesion was considered and the breast alone was removed.

Hadfield<sup>2</sup> in 1930 collected records of forty-two cases of fat necrosis of the breast, to which he added records of three cases. Dunphy<sup>3</sup> has recently reported sixteen cases of fat necrosis observed in the Peter Bent Brigham Hospital between 1923 and 1937. Two of these occurred in the breast and two in the postoperative mastectomy scar.

Trauma and infection are mentioned as etiologic factors in the production of fat necrosis. The frequency of trauma and infection to which the subcutaneous tissues and fat are exposed on the one hand, and the rarity of the lesion on the other, suggest that there must be still another, possibly endogenous, factor. It has been suggested but not proved that pancreatic cells may be transported to such areas, remain latent and be activated by trauma. Neal<sup>4</sup> believes trauma alone may be sufficient, since all cells contain lipase.

According to Hadfield the lesion in the majority of cases is a small mass of traumatized cutaneous fat undergoing quiet and painless sterile autolysis or heterolysis and that its bulk is increased by the accumulation in it of phagocytes engaged in the absorption of fatty acids and fibroblasts initiating repairs. Eventually the lesion cicatrizes and any unabsorbed fat and saponified products become enclosed in mature fibrous tissue. A thick-walled cyst containing dark fluid results and calcification is frequent in the late stages. The central feature of the process is slow, aseptic saponification of neutral fat by blood and tissue lipase, analogous to pancreatic fat necrosis but much milder in degree and independent of any direct action of pancreatic lipase.

In about 40 per cent of the cases there was a history of rather severe trauma to the breast and in most of them the tumor developed where the injury was inflicted. There was no association with lactation and no discharge from the nipple. The history of duration of the tumor varied from two years to ten days. The tumor appears as a firm painless nodule which gradually and at times rapidly increases in size. In more than 50 per cent there were adhesions to the skin and occasionally the typical 'peau d'orange' appearance so characteristic of mammary cancer. In 10 per cent retraction of the nipple was noted. The symptoms which strongly suggest malignancy according to Lee and Adair, are the rapid increase in size, adhesions to the skin, hard consistency, lack of pain and adhesions to

the deeper structures. They conclude that the diagnosis of traumatic fat necrosis of the breast is possible on gross examination and that in the presence of a distinct history of trauma to the breast and a well circumscribed mass, showing rapid increase in size unassociated with pain and without axillary nodes that are firm, an accurate preoperative diagnosis is possible. However, if occasional unnecessary radical mastectomy or irradiation is to be avoided, reliance should be placed on a biopsy.

### OPPORTUNITIES FOR INTENSIVE GRADUATE TRAINING IN OBSTETRICS

The importance of providing medical students and interns with sufficient opportunity for observation and participation in obstetric procedures cannot be overestimated. While many medical schools and teaching hospitals have attempted to organize obstetric instruction so that supervised training of students and interns may provide a maximum utilization of the teaching material available, there are still many patients and considerable free time outside the conventional academic year that may be utilized for undergraduate and graduate study.

A commendable development of the past two years provides practicing physicians in several regions with the opportunity to spend from one to four weeks in hospitals with active ward services in obstetrics. In each the effort is cooperative. The hospital or medical school opens its teaching facilities to the profession, the respective state medical society's committee on maternal health arranges the graduate program and announces the course, and the respective state department of health lends financial aid, usually with funds provided under the Social Security Act. Such courses were successfully conducted at the University of Illinois College of Medicine, Chicago, during the summers of 1937 and 1938 and at the University of Nebraska College of Medicine, Omaha, in July 1938 and were begun at the Indiana University School of Medicine, Indianapolis, in November 1938.<sup>1</sup> Recently through its committee on maternal welfare the Medical Society of New Jersey announced that any practicing physician of New Jersey may attend organized refresher courses given at the Margaret Hague Maternity Hospital in Jersey City.<sup>2</sup>

Each of these intensive intramural courses is designed in essentially the same way. Each is operated on a full one week or two weeks daily schedule with special classes for a limited number of physicians who are given ample opportunity to observe obstetrics as it is practiced under desirable hospital conditions. Lectures in obstetrics and sometimes in pediatrics, conferences, seminars, bedside instruction, antepartum and postpartum clinics,

manikin demonstrations, laboratory exercises and home delivery services all have been included to some extent. Either regular members of the teaching staff or special instructors are assigned, in one hospital twenty six instructors composed the faculty for a class of ten physicians. Fees vary from nothing to \$10 a week for one or two weeks' instruction.

Intensive intramural courses in obstetrics have been given on a somewhat different basis at Tulane University of Louisiana School of Medicine, Department of Graduate Studies, New Orleans, Harvard Medical School, Courses for Graduates and Tufts College Medical School, Boston, University of Michigan Medical School, Department of Postgraduate Medicine, Ann Arbor, University of Minnesota Center for Continuation Study, Minneapolis, Washington University School of Medicine, St. Louis, Mo., Medical Society of the County of Kings and Long Island College of Medicine, Brooklyn, Columbia University, New York City, the New York Polyclinic Medical School and Hospital, New York City, Vanderbilt University School of Medicine, Department of Postgraduate Instruction, Nashville, Tenn., and Duke University School of Medicine, Durham, N. C. Since instruction in these institutions is organized and administered in a different manner from the cooperative courses previously referred to, higher fees are sometimes necessary.

Thus practicing physicians have an opportunity to spend a short period of residence in any one of at least twelve medical centers to learn of the modern methods used in the practice of obstetrics.

### Current Comment

#### GEORGIA PHYSICIANS AND HEALTH OFFICIALS STUDY TOGETHER

Satisfactory progress in public health depends on close cooperation between practicing physicians and dentists and the official health departments, local and state, and through these the health agencies of the federal government. An interesting example of cooperation between health officers and physicians is a series of meetings in the state of Georgia<sup>1</sup> sponsored by the several county medical societies and the county boards of health, with the U. S. Public Health Service cooperating through the Georgia Department of Public Health. Ten cities were chosen for these meetings: Rome, Washington, Americus, Thomasville, Griffin, McRae, Waycross, Swainsboro, Lagrange and Gainesville. The meetings brought to the rural practitioner in all parts of the state the latest information on the four subjects syphilis, the infant, obstetrics and laboratory aids. Through such discussion of common interests in public health, understanding is furthered and progress is made. These are friendly meetings. "Family Gatherings" is the name which Georgia's Health gives them and at the head of the program is the friendly invitation "Come Let Us Reason Together."

# ORGANIZATION SECTION

## HEALTH INSURANCE WITH MEDICAL CARE: THE BRITISH EXPERIENCE

*A Letter from Sir Henry B Brackenbury With a Reply*

*To the Editor* —I have read the book by Dr D W Orr and Mrs Orr entitled "Health Insurance with Medical Care the British Experience" I have read also your review of that book in THE JOURNAL of December 10 last Any author submitting his work for review must be prepared to accept the consequences provided that criticisms are honest and well informed I have no brief for these authors I have never met them But as their book appears to me to be the truest "evaluation of the medical service given under health insurance" in Great Britain (to use your own description of what should be the aim of a work of this kind) that has been written for American readers, and as your review appears to me to be widely mistaken in its facts and not fair in its comments, perhaps you will allow me to make a few frank observations I do this as one who himself worked as a full insurance medical practitioner for the first sixteen years of the operation of the system, who has continued to be associated, both clinically and administratively, with the system till the present time, and as one who has never hesitated to call attention from time to time to certain deficiencies which are freely admitted and has perhaps had some part in the rectification of several of these I speak now of the system as it has been operating during recent years, and I am concerned only with the picture presented of its methods and effects in Great Britain and not at all with the question of its applicability to America

The main items of your indictment of the authors are (a) that they have sought the opinion of inappropriate and biased members of the profession only, (b) that they have accepted favorable opinions while ignoring what you regard as notorious facts which are unfavorable, (c) that they have had improper regard to the opinions of insured persons as to the way in which the system affects them, (d) that in the bibliography there is a "complete omission" of books, reports and pamphlets which tell against their conclusions This would be a damning indictment if true, but let us consider it

In the main the medical practitioners consulted by the authors were those who have had considerable experience as doctors in the insurance service or as administrators of that service Many of them have had both I should have regarded such experience as a valuable qualification for the expression of an opinion, not, as you regard it, as a criterion of unreliability I suppose you adopt the principle of the proverb "observers see most of the game" But this is very often not true and it is the opposite of the truth if the observers know little or nothing of the nature of the game or of the rules under which it is played There is unfortunately no consultant and specialist service under the British insurance scheme (except indirectly to a very limited extent), and in consequence many of

the most eminent members of the profession have no practical knowledge of its working at all Some consultants, however, have interested themselves in its administration from the medical side I have never heard from such a consultant an opinion adverse to the scheme as a whole Of course it is possible to find a few individuals among the doctors working the scheme who dislike it Dr and Mrs Orr found one among the relatively few whom they interviewed But why should you view with suspicion, and characterize as untrue, the general and collectively expressed opinion of some 20,000 doctors who know from their personal experience what they are talking about?

The charge that the authors have ignored the facts which are not in harmony with their conclusions is refuted to some extent in your own review In at least two instances you point out that, having quoted certain statements of their informants, they go on to give facts which are not in harmony therewith and to express their own opinion that these statements at least require serious modification Again, I should have thought that, in any impartial review, this would have been counted to them for righteousness, not thrown up against them as contradictory You proceed, however, to point to two matters in which you allege that your charge is true, one relates to excessive prescribing due to the whim or to the pressure of patients, the other to attendances at the outpatient departments of hospitals

As to the former, in spite of my long experience, I know nothing of the "continuous flood of letters sent out by regional medical officers" with regard thereto, nor of the "many complaints in official reports, including those of the Ministry of Health, of excessive prescribing to satisfy the demands of the patient" As to the latter I have never once heard it said that "the repeated appeals for financial aid for hospitals were largely due to the increased burden created by national health insurance," a statement which you allege is "continuously" made There is no restriction on the ordering of "proper and sufficient" medicines for an insured patient If there are some prescribers who, either through inexperience or through being unduly influenced by the advertisements of wholesale druggists, order expensive preparations when an official one from the British Pharmacopoeia the British Pharmaceutical Code or the National Formulary would be equally efficacious and less costly, and if the attention of such prescribers is drawn to this fact that is a merit, not a demerit of the system and even in such cases the practitioner is always given the opportunity of showing that in the particular instance the more expensive preparation was necessary or desirable After careful investigation it is quite clear that the "waiting lists" of a number of hospitals are due to causes almost entirely unrelated to national health insurance and so

far as it may be true that the system has led to the discovery of the need of many insured patients for a course of really specialist treatment or to a realization by their dependents of the desirability of early medical attention for which they are unable to pay their own doctor, this is surely an indirect effect of the system which is beneficial, not detrimental.

With regard to the authors having sought the opinions of insured persons themselves, your remarks appear to be either obscurantist or irrelevant, yet this you describe as your "sharpest criticism." Your parallel with the "thousands of testimonials to the efficiency of the panacea" produced by a "distributor of nostrums" does not hold. The gravamen of the charge against the insurance system is that it produces perfunctory medical attendance and that insured persons do not get a square deal as regards interest and attention from their doctors. Knowledge, skill and therapeutic results doubtless vary from doctor to doctor, for it must be remembered that all insurance practitioners are private doctors also. A novel and valuable feature of the investigation by Dr. and Mrs. Orr is the conclusion, from the mouths of insured persons themselves, that this charge (with doubtless a few individual exceptions) is untrue. It is well known to be so both by doctors and by the officials of Approved Societies in Great Britain.

Finally, what are these books and reports which have been deliberately omitted from the bibliography because they do not bear out the opinions of the authors? I do not mean publications written during the earlier years of the national insurance service nor those which merely criticize some detail of the service or point out some particular imperfection. I mean such as may be said to condemn the whole system in general or in principle or, in the words of your review, "contradict many of the conclusions of the book as to the character of the service given." I assert quite definitely that neither of the reports which you specifically mention does anything of the kind.

Let me not be misunderstood. There are still admitted imperfections in the detailed working of the system, but these, like others of more importance that have already disappeared, can be got rid of by negotiation. There are deficiencies its scope needs extending in several directions. There are some practitioners whose work is less efficient than might be desired; there are perhaps a few who have accepted more responsibilities than they can well undertake together with their noninsurance practice. Further, I agree that it is impossible to estimate even approximately, how far national health insurance has contributed to the manifest betterment of the public health that has taken place during the past twenty-five years, since so many other favorable factors have been at work, and any comparison in this connection between America without such a service and Great Britain with one, appears to be entirely irrelevant to the issue with which I have been concerned in this letter.

Yours faithfully,

HENRY B. BRACKENBURY  
30 West Heath Drive  
Hendon, N. W. 11  
England

This letter was referred to the Bureau of Economics of the American Medical Association, which makes further comments.

*To the Editor*—We take this up in the order in which it is written.

(a) "That they have sought the opinion of inappropriate and biased members of the profession only." There is no statement that these are inappropriate and biased but that only those who were in favor of the scheme were consulted. The book speaks for itself on this subject—in that the authors apparently found only one critic. Yet the files of the *British Medical Journal* for Sept. 12, 1936, for Oct. 17, 1936, and for July 24, 1937, and the *Birmingham Medical Review* for June 1935 are sufficient evidence that there are a number of physicians who denounce this system in stronger language than that used in the review or than has ever been used in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. Quotations from physicians who have practiced under the panel system and later gone to other countries, and who give similar opinions, may be found in the *Canadian Medical Association Journal* for February 1938, pages 188-189, and the *South African Medical Journal* for Oct. 28, 1933, the *British Journal of Tuberculosis* for April 1934 is another illustration.

(b) "That they have accepted favorable opinions while ignoring what you regard as notorious facts which are unfavorable." While here, as with the other statements, it might be pleaded that the indictment does not represent the position of the review, it is true that there is no reference in the Orrs' book to excessive prescribing, to lack of preventive activities, to an increase in morbidity, to restrictions on prescribing (which will be mentioned later), to lack of postgraduate training, to the separation of medical service into two classes, and to the necessity of a young physician buying his opportunity to start a practice.

(c) "That they have had improper regard to the opinions of insured persons as to the way in which the system affects them." Will Sir Henry claim that the lay public is capable of judging the efficacy of a medical service when it has no opportunity for comparison with other services and no technical training? Just how does this sort of an opinion differ from the testimonials offered by quacks as proof of the satisfactory character of their services?

(d) "That in the bibliography there is a 'complete omission' of books, reports and pamphlets which tell against their conclusions." The review itself lists some of these documents, others are listed in this comment.

Sir Henry objects to the statement as to "excessive prescribing due to the whim or the pressure of patients." The *British Medical Journal* for March 1, 1930, page 405, in commenting on a statement in the Report of a National Advisory Committee to the effect that "the insured person would have the right of complaint against the insurance practitioner under article 32 of the Medical Benefit Regulations, 1928, for refusing to prescribe an alleged drug" says:

If (as the committee now appears to lay down) 'any question is to be regarded as including the right of a patient to have given to him, or prescribed to him the drug or preparation

which he thinks he ought to have, irrespective of whether the practitioner thinks it appropriate or not, the medical profession could not for a moment countenance the right of an insured person to raise any such question. The word "refusing" seems to imply a "demanding" on the part of the patient. It would be a topsy-turvy kind of medical practice in which the patient named the drug and the doctor obediently prescribed it, or, greatly daring, declined to do so.

As to the complaints against excessive prescribing, see the Report of the Chief Medical Officer for 1935 in the January 1937 issue of *Public Health* and the Eighteenth Annual Report of the Ministry of Health, 1936-1937, page 187.

As to the statement that there is no interference with prescribing, the Report of the Ministry of Health mentioned in the preceding paragraph (page 189) says: "Regional Medical Officers paid 891 visits in 1936, compared with 840 in 1935, to doctors whose prescribing appeared to call for explanation." (The statement in the review regarding the mass of letters written was based on statements made to the reviewer personally and files of letters shown to him by the Regional Medical Officer of Birmingham in 1931.)

The reviewer has investigated health insurance in Great Britain and has traveled from Glasgow to London by automobile, during which time he repeatedly saw the sign-boards of hospitals along the road asking for assistance and was repeatedly told by people in various parts of England that there was an increased burden on the hospitals because of the tendency of panel physicians working on a per capita payment plan to send many cases to the hospital, where, incidentally, the panel physician usually was not allowed to practice. A Canadian physician, who was a former panel practitioner, writing in the *Canadian Medical Association Journal* for February 1938, said: "The busy panel practice resolves itself into a 'clearing station'. The only major decision made is whether the patient is really ill or not. If he is really ill he is sent to the local hospital, and the expense and responsibility are shifted to that quarter. If he is not considered to be really ill some of the panel prescriptions will be prescribed." (See also the following statement from Report on the British Health Services, by P. E. P., page 162: "The panel doctor, at any rate in large towns, often has neither the facilities nor the equipment which, as precise diagnosis becomes daily more possible, are necessary to provide an adequate service. As a result he passes on his patients to the hospital and specialized clinics and often enough he tends to become little more than an agent for signing certificates.")

It is not universally agreed that "the system has led to the discovery of the need of many insured patients for a course of really specialist treatments." This statement is not borne out by many of the other criticisms, including the complaints of those concerned with the cure of tuberculosis that delay in discovering this disease exists to an extent fully equal to that about which a similar complaint is made in the United States.

There is no charge that the books omitted "condemn the whole system in general" but they do as stated contradict many of the conclusions of the Orrs' book as to the character of the service given.

Complaint of the lack of preventive measures is found in the Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1937: "On the

State of the Public Health," pages 53-55. Reference is made in the review to some of the reports that describe the steady increase in morbidity as recorded in days during which a benefit was received for incapacity to work and the over-medication previously mentioned. Sir Henry repeats the now familiar objection to any comparison of vital statistics as "entirely irrelevant to the issue." Perhaps he is not aware that the advocates of health insurance for years quoted often inaccurate and distorted vital statistics to bolster up their claim that health insurance had a favorable effect on morbidity and mortality statistics. Now that it has been definitely shown that the comparison of such statistics at almost every point fails to show any superiority of insurance countries, we are constantly assured that such comparisons are unjustifiable.

As appropriate to this discussion, attention might also be called to the strenuous opposition that is being raised by the branches of the British Medical Association in Australia and New Zealand to the introduction of health insurance in those countries and to the fact that they fail to have their opinions changed by the arguments offered by Sir Henry on his recent visits to those countries. It would seem that physicians in the British Commonwealth of the Nations would probably be sufficiently familiar with conditions in the home country to render them especially competent to draw accurate conclusions as to the desirability of the British system as compared with the system of private practice in Australia and New Zealand.

The charge of bias is based primarily on the continuously applied and sometimes directly stated claim that there are practically no criticisms by panel physicians—a statement that is disproved by the quotations in the medical journals to which reference is previously made. The question is not raised as to books that "condemn the whole system in general," because no one disputes the fact that the vested interests—financial, professional and political—created by the system of health insurance have made any attempt at abolition of the system hopeless. There is also full recognition of the fact that the British Medical Association is engaged in a splendid effort to make health insurance work, and certainly the reviewer would not criticize that effort. It is believed, however, that the attempt "to sell" the British system to America by one-sided presentation of its character is something against which the medical profession in the United States should protest. In other words, the reviewer takes the same stand which Sir Henry takes in his quotation and endorsement of the Memorandum of Evidence submitted on behalf of the British Medical Association to the Royal Commission on National Health Insurance, where he says:

The organization of a National Health Insurance scheme is not necessarily, or even probably, the best means of utilizing limited resources for the promotion of national health. It is more than likely that there are a number of other directions in which, severally or collectively, a corresponding expenditure would produce an even more satisfactory return.

The medical profession in America has simply maintained "that there are a number of other directions in which, severally or collectively, a corresponding expenditure would produce an even more satisfactory return", apparently the physicians of Australia and New Zealand agree.

# LEGISLATION OF INTEREST TO PHYSICIANS CONSIDERED BY STATE LEGISLATURES IN 1938

Prepared by T V McDavitt of the Bureau of Legal Medicine and Legislation

(Continued from page 556)

## IV LEGISLATION REGULATING THE DISTRIBUTION OR POSSESSION OF FOODS, DRUGS, COSMETICS AND BIOLOGICS

**NARCOTICS**—The uniform narcotic drug acts in force in Louisiana and New Jersey were so amended this year<sup>92</sup> as to make cannabis or marihuana a narcotic drug within the meaning of the act. The New York uniform narcotic drug act was so amended this year<sup>93</sup> as to define cannabis to include "the following substances under whatever names they may be designated (a) the plant, its leaves or tops of the plant *Cannabis sativa* L., from which the resin has not been extracted, (b) the resin extracted from such plant, and (c) every compound, manufacture, salt, derivative, mixture or preparation of such resin, or of such plant from which the resin has not been extracted."

An amendment<sup>94</sup> to the Massachusetts Narcotic Drug Act raises to ten years from five years the term of imprisonment that may be imposed on a person convicted of unlawfully selling, delivering, furnishing, giving or exchanging a narcotic drug or possessing a narcotic drug for such purpose.

A new Mississippi law<sup>95</sup> amends the law relating to marihuana with respect to the circumstances under which a warrant may issue to search premises on which violations of the law are suspected of being perpetrated.

A bill was killed in Indiana<sup>96</sup> to make it unlawful to sell or otherwise distribute any commodities intended for smoking in which there is any *Cannabis indica*. The bill also proposed to make it unlawful for any person to possess or smoke cigarets, cigars or tobacco or other commodities intended for smoking containing any of the drug mentioned.

An unsuccessful attempt was made in Mississippi<sup>97</sup> so to amend the uniform narcotic drug act as to prohibit the distribution of barbituric acid compounds except on the written prescription of a licensed physician, dentist or veterinarian.

Unsuccessful attempts were made in New Jersey<sup>98</sup> to create a state bureau of narcotic control to supervise the use of narcotic drugs in the state, to license persons to sell, distribute or dispense narcotic drugs at wholesale or retail and to enact such regulations as may be necessary to accomplish those purposes.

**BARBITURIC ACID DERIVATIVES**—Unsuccessful attempts were made in Mississippi<sup>99</sup> to prohibit the retail sale or distribution of barbituric acid compounds except on the written prescription of a licensed physician, dentist or veterinarian. The legislature of South Carolina reacted unfavorably to attempts<sup>100</sup> to repeal the law enacted in 1937 prohibiting the retail sale or distribution except by virtue of the prescription of a licensed physician, dentist or veterinarian, of the "synthetic drugs known as barbiturates and their compounds."

**SULTANILANIDE — DINITROPHENOL — DIETHYLENE GLICOL**—A resolution adopted in Massachusetts<sup>101</sup> creates a special commission to investigate the desirability of legislation to prohibit, except on the

prescription of a licensed physician, the sale of amino sulfamidobenzene, dinitrophenol or sulfanilamide. This commission was also charged with the duty of investigating the desirability of legislation prohibiting the sale of drugs containing as a solvent ethylene glycol, diethylene glycol or any derivative thereof, and legislation prohibiting the retail distribution of drugs, which if taken in whole or in part may cause death, unless the containers of such drugs have labeled thereon statements as to how much if taken at one dose would kill and the appropriate antidote.

**BIOLOGICS**—A bill was killed in Massachusetts<sup>102</sup> to prohibit the distribution of vaccine or other virus, toxin, anti-toxin or other serum, unless the container of such substance has affixed thereto a label stating the exact content of the virus or serum, the date when manufactured, the place of manufacture and the name of the manufacturer and a statement as to the specific disease against which it is claimed to immunize.

**LIMITATION ON MANUFACTURE OR SALE OF NEW DRUGS**—Bills were killed in Georgia<sup>103</sup> to prohibit the sale, dispensing or distribution in the state of any new drug until the drug should first have been tested chemically by the state chemist and its medical value approved by him and the director of the state department of health. A similar bill was likewise killed in Mississippi<sup>104</sup>.

**FOODS, DRUGS, COSMETICS AND THERAPEUTIC DEVICES**—Extensive amendments to the existing state pure food and drug act were adopted in Virginia<sup>105</sup>. Among other things, the new law provides that the term "drug" includes all substances and preparations recognized in the official United States Pharmacopoeia, official Homeopathic Pharmacopoeia of the United States, or official National Formulary, or any official supplement to any of them and all substances and preparations intended for use in the diagnosis, cure, mitigation, treatment or prevention of disease in man or other animals and all substances and preparations other than food and cosmetics, intended to affect the structure or any function of the body. The new law also brings "cosmetics," defined as "all substances and preparations intended for cleansing, or altering the appearance of, or promoting the attractiveness of, the person," within the purview of the act.

Bills to enact new laws prohibiting the manufacture, sale or distribution of adulterated or misbranded foods, drugs, cosmetics and therapeutic devices were considered and killed in Mississippi<sup>106</sup> and New York<sup>107</sup>.

## V BILLS AFFECTING HOSPITALS

### A Hospitals Generally

**CONTRACTS FOR HOSPITALIZATION, HOSPITALIZATION INSURANCE**—Legislation to authorize the formation of corporations to provide on a "nonprofit basis" "hospital care" to their members and subscribers has already been discussed in this survey immediately following the introduction

**PAYMENT BY STATE FOR CARE RENDERED INDIGENT PATIENTS**—The Mississippi law authorizing the payment by the state of bills of approved hospitals in the state for care rendered indigent sick persons was amended by two laws enacted this year. One new law<sup>108</sup> provides that if adequate hospital facilities are lacking in a county bordering on another state, an acceptable hospital in a contiguous county in the neighboring state treating an indigent resident of Mississippi may be recompensed by the state. The other law<sup>109</sup> states in detail the certificate that must be extended by a licensed physician and two other residents of the county in which the applicant for hospital care to be paid for by the state resides, which certificate must be procured on behalf of each indigent person cared for before the state will reimburse the hospital caring for him. The law also requires the state hospital commission, which administers the law, to report to the clerk of the chancery court monthly a list of persons in his county who have received hospital care under the act.

An unsuccessful attempt was made<sup>110</sup> so to amend the same law as to reduce the amount the state would reimburse hospitals for care rendered indigents to \$150 from \$250 a day for each indigent cared for.

Bills to provide a procedure whereby hospitals might be reimbursed by the state for treatment and care rendered indigent persons injured in motor vehicle accidents were rejected in New York.<sup>111</sup>

**INSURING PAYMENT OF HOSPITAL BILLS**—The Virginia lien law was so amended this year<sup>112</sup> as to provide that if a personal injury results in death the lien of a hospital caring for the decedent can be asserted either against (1) a judgment or compromise accruing because of the injury and death or (2) the general state of the decedent, but not against both. A new New Jersey law<sup>113</sup> creates a lien in favor of state and county institutions and charitable institutions maintained in whole or in part by state or county funds, to which persons have been committed or admitted by virtue of title 30 of the Revised Statutes against the property of persons confined there and receiving care and treatment. A new Louisiana law<sup>114</sup> requires any person who has received treatment in any of the charity hospitals of the state<sup>115</sup> for injuries which might entitle him to damages or compensation and who files suit for the recovery of such damages or compensation to cause a copy of the petition in any such suit to be served on the hospital from which he received treatment.

A bill was killed in Rhode Island<sup>116</sup> to grant hospitals rendering services to persons injured through the negligence of others liens on all rights of action recoveries judgments or settlements accruing to the injured persons by reason of their injuries.

An unsuccessful Virginia bill<sup>117</sup> proposed that the proceeds of a judgment based on a wrongful death should be paid to the personal representative of the decedent and after the payment of the cost of suit and reasonable attorney's fees there should be paid the charges of hospitals physicians and nurses incurred during the last illness of the decedent but not to exceed \$200 in the case of the hospital and \$50 to each such

physician and nurse. The New Jersey legislature failed to act on a bill<sup>118</sup> which proposed that in the distribution of the assets of an insolvent decedent hospital charges and expenses for the last illness should be on a par with judgments entered against the decedent in his lifetime, funeral charges and expenses, and physicians' and nurses' bills during the last illness and should have precedence over all other claims.

**LICENSING OF ALL PRIVATE HOSPITALS**—An unsuccessful Massachusetts bill<sup>119</sup> proposed to prohibit the operation of private hospitals except by virtue of a license issued by the department of public health, which was to be empowered to make rules and regulations for the operation of such institutions.

**HOSPITAL EMPLOYEES**—A resolution was adopted in Massachusetts<sup>120</sup> which requires the department of labor and institutions and the department of public health to conduct an investigation relative to the hours of labor of women and children in hospitals.

Bills to limit the hours of employment in hospitals of all employees, male or female, to not more than eight hours in any one day, nor more than forty-eight hours in any calendar week were killed in two states.<sup>121</sup>

**REQUIRED REPORTS**—A new Louisiana law<sup>122</sup> requires the person in charge of a hospital who has first knowledge of a death occurring suddenly, accidentally, by violence, under suspicious circumstances, or from abortion to notify the appropriate coroner and district attorney.

Bills to require hospitals to report to specified authorities in the instances noted were killed in Massachusetts and New Jersey. The bills in Massachusetts<sup>123</sup> would have required a report when caring for a case of induced abortion. The New Jersey bills<sup>124</sup> would have required a report when any person admitted was found infected with venereal disease, one bill<sup>125</sup> even going so far as to propose to require a hospital to subject every patient admitted to a Wassermann or other approved blood test for the detection of syphilis.

**ADMISSIBILITY OF HOSPITAL RECORDS IN EVIDENCE**—A new Louisiana law<sup>126</sup> provides that whenever a certified copy of the chart or record of either of the charity hospitals of the state is offered in evidence in court it is to be received as prima facie proof of its content.

**MISCELLANEOUS**—An unsuccessful attempt was made in Massachusetts<sup>127</sup> to require the state department of public health to furnish not less than two oxygen tents to each hospital in cities of 30,000 or more population, to be used without charge on patients whom the board of health in such city or town deems needy. Another unsuccessful Massachusetts bill<sup>128</sup> proposed to establish a hospital lottery commission which was to be authorized to permit any hospital in the state to conduct a lottery under such plan and subject to such rules and regulations as might be adopted by the commission. Bills were rejected in New York<sup>129</sup> to require hospitals to permit a patient's attorney to inspect all hospital records relative to the patient. An unsuccessful attempt was made in Massachusetts<sup>130</sup> to require any chartered hospital in the state to accept any patient when requested to do so by a licensed physician. An unsuccessful Mississippi bill<sup>131</sup> proposed to make it unlaw-

ful for any hospital to assign any nurse not a graduate or registered nurse to a special case unless the nurse receives the compensation paid for the nursing care rendered

### B Governmental Hospitals

**STATE HOSPITALS FOR THE TREATMENT OF TUBERCULOSIS**—A new Indiana law<sup>132</sup> authorizes the establishment of a state hospital for the treatment of tuberculosis, to be known as the Southern Indiana Tuberculosis Hospital. The law specifically provides that the governing board of the hospital staff members and other employees shall not be subject to any suit or claim for malpractice for care or treatment rendered therein.

An unsuccessful attempt was made in Virginia<sup>133</sup> to appropriate \$250,000 for the erection and equipping in Southside of a sanatorium for the treatment of tuberculosis.

**STATE CANCER HOSPITALS**—A law was adopted in Rhode Island<sup>134</sup> which authorizes the governor to appoint a commission of five, not less than three of whom must be medical practitioners, who, together with the director of public welfare and the director of public health, are to make a thorough study and investigation as to the advisability of establishing a cancer hospital at the state institution at Howard. This commission is to report to the general assembly not later than Feb. 1, 1939, the results of that study and make such recommendations as it may deem proper.

An unsuccessful attempt was made in New York<sup>135</sup> to authorize the establishment of three state hospitals for the care and treatment of persons afflicted or threatened with cancer or allied diseases.

**STATE HOSPITALS FOR THE TREATMENT OF INFANTILE PARALYSIS**—Unsuccessful attempts were made in Massachusetts<sup>136</sup> to provide additional facilities for the treatment of persons crippled by infantile paralysis or other crippling conditions. One bill sought the construction of a health center adjacent to Buzzards Bay while the other sought a 100 bed ward in the Lakeville State Sanatorium.

**STATE HOSPITAL FOR TREATMENT OF CRIPPLED CHILDREN**—A law was adopted in Louisiana<sup>137</sup> directing the state hospital board and the state board of health to establish and operate a "hospital bath houses and other necessary and/or incidental facilities at Hot Wells, Louisiana, for the care and treatment of crippled children and/or the care and treatment of the indigent and destitute."

**COUNTY GENERAL HOSPITALS**—Authority was given for the holding of an election in July 1938 in York County S. C., in which the electorate were to be given the chance to approve or disapprove the question of issuing a bond issue of \$175,000 for constructing and establishing a county general hospital. The staff of this hospital, if it is established, is to consist of all licensed physicians residing in the county.<sup>138</sup>

**COUNTY TUBERCULOSIS HOSPITALS**—A new Mississippi law<sup>139</sup> authorizes one or more counties, separately or jointly, to establish, maintain and operate a "tubercular" hospital. A South Carolina law<sup>140</sup> empowers the counties of Dillon, Horry and Marion, or one or

more of them to contract with the Florence-Darlington Tuberculosis Commission for the erection and operation of a hospital for the care and treatment of residents of the counties indicated afflicted with tuberculosis.

**COUNTY MATERNITY HOSPITALS**—A new New Jersey law<sup>141</sup> authorizes the board of chosen free holders of any county of the first class to establish and operate a maternity hospital.

**CLINICS FOR THE TREATMENT OF VENEREAL DISEASES**—A new South Carolina law<sup>142</sup> requires the county health department of Greenville County to operate a "venereal clinic" to render services free of charge to those unable to pay and to require those persons able to pay to pay a reasonable charge for the services.

An unsuccessful attempt was made in Massachusetts<sup>143</sup> to authorize the department of public health, either alone or with the cooperation of local boards of health, hospitals, dispensaries or other agencies, to establish clinics throughout the state to provide treatment for persons suffering from gonorrhea or syphilis.

## VI WORKMEN'S COMPENSATION LEGISLATION

So far as can be ascertained no workmen's compensation legislation of interest to the medical profession was enacted in 1938. The following are the more important legislative proposals which failed of enactment. A Massachusetts bill<sup>144</sup> to limit the right of a worker to select his own physician by requiring him to select a physician from a list established by the department of industrial accident, which, however, was to be required to list all physicians applying for such listing, a Rhode Island bill<sup>145</sup> to provide compensation for silicosis and asbestosis contracted in the course of an employment, a New Jersey bill<sup>146</sup> to make it less difficult for a workman to establish the fact that a hernia resulted from an industrial accident, bills in Rhode Island<sup>147</sup> and Virginia<sup>148</sup> to require the employer to furnish reasonable medical, dental and hospital services and medicines to an injured employee without limit as to amount or time, a Kentucky bill<sup>149</sup> to limit an employer's liability for medical and hospital services to the first six months after an industrial accident and to \$200 in amount, reserving in the compensation board, however, the right to order an extension of the period of treatment or of the limit of expense, a New York bill<sup>150</sup> to require an employer to provide an injured workman with such dental care as might be necessary to restore him from the effects of an industrial accident, and other New York Bills<sup>151</sup> proposing in general to limit the right of hospitals and employers to employ physicians on a salary basis to treat injured workmen.

## VII MISCELLANEOUS LEGISLATION

**COMPULSORY HEALTH INSURANCE, SOCIALIZED MEDICINE**—A new New York law<sup>152</sup> creates a state commission to study and recommend ways and means for minimizing risks of illness through the extension of public health services, for furnishing adequate medical care for persons of low income, the cost to be met from public funds, for making public funds available for the support of medical education and for studies, for raising the standards of medical practice, for medical care to the indigent, for using private institutions in allocating

public funds for the rendition of medical services to the public, for effecting adequate administration and supervision of the health functions of the state government and, if deemed advisable, for consolidating under a separate department all federal and state health and medical services and activities. This commission is to report to the legislature before Feb 15, 1939.

The legislature of New York failed to act on two other proposals which if adopted would have tended to socialize the practice of medicine. One bill<sup>153</sup> would have authorized the state department of social welfare to supply to all married persons having an income of less than \$1,200 annually and all single persons having an income of less than \$900 annually necessary medical, dental and hospital services free of charge. The bill proposed that the medical services be rendered by such licensed physicians, dentists, nurses and hospitals as would agree to render services in such manner as the medical assistance board, which the bill proposed to create, would designate. The other New York bill<sup>154</sup> proposed to authorize the state department of health to render free of charge to all inhabitants of the state "all medical surgical dental, nursing care and treatment and all other services and facilities known to science and designed or adapted for use in all cases of sickness, accidents and childbirth maintenance in hospitals, the furnishing and supplying without cost of medicines drugs," and all other necessary equipment and supplies. The bill proposed to increase the staff of the department so as to include all registered physicians, dentists, pharmacists, technicians, research and laboratory workers and all other persons practicing allied professions who elected to serve and to pay them salaries in accordance with the schedule fixed in the bill. The department was to be authorized to exercise exclusive control over all public hospitals and was to have complete supervisory powers over all private hospitals and the staff, officers and employees thereof.

Proposals to enact compulsory health insurance schemes were rejected in Massachusetts,<sup>155</sup> New York<sup>156</sup> and Rhode Island.<sup>157</sup> These bills proposed a system of compulsory and voluntary sickness insurance the benefits of which were to consist of cash and all forms of medical dental and hospital services.

**TREATMENT FOR INFANTILE PARALYSIS AND OPHTHALMIA NEONATORUM AT PUBLIC EXPENSE**—The governor of New York vetoed a bill<sup>158</sup> to require local boards of health and health officers to provide suitable surgical medical and hospital treatment and care to persons infected with or exposed to infantile paralysis. Two unsuccessful attempts were also made in New York<sup>159</sup> to require the district state health officer in whose jurisdiction a case of ophthalmia neonatorum occurred to provide hospital, medical and special nursing care.

**PNEUMONIA CONTROL PROGRAMS**—A new New Jersey law<sup>160</sup> appropriated \$25,000 to the state department of health for the fiscal year ending June 30 1938, to be expended in the purchase and distribution of type I and type II pneumonia serum, to be available free of cost to persons afflicted with pneumonia and financially unable to purchase the necessary serum. A supplement to this law appropriating an additional \$10,000 for the fiscal year ending June 30 1939, was also enacted.<sup>161</sup>

A bill failed of enactment in Virginia<sup>162</sup> which proposed to direct the state board of health to establish a statewide collapse therapy program to be made available to all tuberculosis patients in need of such treatment. Such program is to include facilities for pneumothorax and for surgical procedures including phrenic nerve operations pneumolyses and

thoracoplasties in all public hospitals or institutions. The state board of health is further directed to establish a statewide follow-up program for tuberculosis patients including the continuance of pneumothorax of all marginal and indigent patients without cost to them and to provide for the giving of such treatment by private physicians, who are to be paid by the state.

**MARRIAGE REQUIREMENTS**—Laws to require, as a condition precedent to the issuance of marriage licenses that both parties to the proposed marriages present certificates from physicians that they are free from stated venereal diseases, were enacted in Kentucky,<sup>163</sup> New Jersey,<sup>164</sup> New York<sup>165</sup> and Rhode Island.<sup>166</sup> The Kentucky and Rhode Island laws require freedom from all venereal diseases, while the New Jersey and New York laws require freedom only from syphilis. The Rhode Island law in addition requires freedom from tuberculosis in the infectious stages. The certificates of the physicians under all four laws must be based on standard laboratory tests and also in Kentucky and Rhode Island on physical examination. All the laws referred to, except the Kentucky law, are now in effect. The Kentucky law does not become effective until March 1, 1940.

Unsuccessful attempts were made in five states<sup>167</sup> to require as a physician's certificate as to freedom from stated venereal diseases with respect to both parties to a proposed marriage as a condition precedent to the issuance of marriage licenses.

A resolution adopted in Ohio<sup>168</sup> authorizes the establishment of a special commission to make a study of the prevention of congenital syphilis and of the prevention of the spread of venereal disease through marriage by requiring an antenatal physical examination to determine the presence of a venereal disease before a license to marry is granted by the probate court.

**VENEREAL DISEASES**—Unsuccessful attempts were made in Georgia<sup>169</sup> and Louisiana<sup>170</sup> to amend existing laws relating to venereal diseases so as to authorize appropriate local health authorities to examine persons infected with or reasonably suspected of being infected with venereal diseases, to quarantine such persons and to require such persons to submit to treatment until cured. A New Jersey bill,<sup>171</sup> which failed of enactment, proposed to require a person infected with a venereal disease to consult at once a licensed physician or any hospital or clinic maintained for the treatment of such diseases. The bill also proposed to require hospitals to subject every patient to a Wassermann or other approved blood test for the detection of syphilis. The Georgia and New Jersey bills referred to also proposed to require a physician treating a patient for venereal disease to notify stated health authorities. Other proposals with respect to venereal disease are considered in the section immediately following.

**PHYSICAL EXAMINATION OF FOOD HANDLERS OR DOMESTIC SERVANTS**—A law enacted in South Carolina<sup>172</sup> prohibits the employment on and after Jan 1, 1940 in Greenville County of a domestic servant unless the servant obtains a certificate from the county health department showing that he or she is either free from

syphilis or under proper and adequate treatment for that disease. Servants must procure such a certificate annually thereafter.

A bill was killed in New York<sup>173</sup> to prohibit the employment as a domestic servant of any person with a communicable disease if such person in the course of his work would attend children or perform any work in connection with the handling of food. The bill proposed to require every domestic to submit within sixty days after the enactment of the bill to necessary medical examinations.

Bills were killed in four states<sup>174</sup> to require food handlers to be examined at least semiannually by licensed physicians and to prohibit a person from acting as a food handler unless possessed of a certificate from a physician that he or she is not infected with any venereal disease or other communicable disease.

**BLOOD TRANSFUSIONS**—The Massachusetts legislature referred to its next annual session a bill<sup>175</sup> proposing a regulatory act for the use of blood for transfusion purposes. The bill would have banned the use of the blood of any donor who had ever had syphilis or questionable sexual intercourse within three months of the transfusion. Prior to the use of any blood the donor was to be required to submit to a serologic test and to a physical examination.

**ASELUALIZATION**—The legislature of New Jersey<sup>176</sup> rejected a proposal to authorize the sexual sterilization of all persons "likely to procreate idiot, imbecile or feeble-minded progeny."

**BLOOD GROUPING TESTS**—A new New York law<sup>177</sup> supplements the code of criminal procedure by providing that whenever it shall be relevant in any criminal proceedings to determine the parentage of any child, or the identity of any person or corpse, the court, on the motion of the defendant, shall order any party to such action and the person involved in the controversy to submit to serologic blood tests and the results thereof shall be receivable in evidence but only where definite exclusion is established. Such tests are to be made by physicians appointed by the court from a list of physicians certified by the state medical society.

An unsuccessful attempt was made in New Jersey<sup>178</sup> to provide for compulsory blood grouping tests in illegitimacy actions the results of which would have been admissible in evidence or where definite exclusion was established.

**VACCINATION**—A new Virginia law<sup>179</sup> authorizes local boards of health, in addition to rights previously possessed at law, to require, whenever they deem it necessary to prevent an epidemic, the compulsory administering of toxoid.

Two bills were killed in Massachusetts<sup>180</sup> which proposed to provide that no person should be required to submit to any form of vaccination or inoculation as a condition precedent to admission to any public institution. One of these bills<sup>181</sup> also proposed to prohibit the display or distribution in the public schools of medical or surgical advertising or propaganda.

**EXAMINATION OF PUBLIC SCHOOL PUPILS**—A bill was defeated in New York<sup>182</sup> to require the semiannual examination of public school pupils by duly licensed psychiatrists and to authorize the commitment to a state institution of pupils found to be afflicted with a mental disability of such a type as would interfere materially with the instruction of other pupils. A bill was killed in New Jersey<sup>183</sup> to require medical inspectors, principals and teachers in charge of public schools to

make at least annual eye and ear tests of pupils with such scientific devices as may be approved by the commissioner of education. The board of education of each school district was to be authorized to appoint specialists to make the required examinations.

**MEMBERSHIP IN COUNTY MEDICAL SOCIETY CONDITION PRECEDENT TO RIGHT TO PRACTICE**—The Mississippi legislature again killed a bill<sup>184</sup> proposing to create in each county a county medical association and condition the right of a physician to practice on membership in the county medical association of the county of his residence. The association was to be in charge of all public health work in the county, and the rendering of care to the indigent sick was to be authorized to appoint from its membership a county health officer and was to be given full power to isolate and treat persons afflicted with infectious venereal disease for such times and under such restrictions as might be proper.

**MISCELLANEOUS**—The following miscellaneous bills all failed of enactment: a New York bill<sup>185</sup> to pay \$75 to the parents in every future case of legitimate childbirth, a Massachusetts bill<sup>186</sup> to require an applicant for a license to operate a motor vehicle to furnish a written certificate after an acceptable medical examination, showing physical and mental fitness with a favorable intelligence rating, a New York bill<sup>187</sup> to make it the duty of school authorities to purchase and distribute to all pupils of kindergarten and primary grades such quantities of cod liver oil or a concentrate thereof of equal vitamin content as the school or private physicians may prescribe, a Rhode Island bill<sup>188</sup> to provide for the examination by a psychiatrist, to be provided by the department of public welfare of every person indicted for an offense punishable by life imprisonment or who is indicted for any offense and had been previously indicted, and a New York bill<sup>189</sup> to create a state lunacy authority and subordinate local lunacy boards which were to make psychiatric, psychologic and psychometric examinations of all persons indicted for felonies and to report their observations to appropriate local courts. The state lunacy authority was to have power to review the findings of local lunacy boards and to examine inmates of a state institution for the insane or mentally defective prior to their release.

### SQUARE DEAL IN MEDICAL CARE

The National Dental Association and the National Nurses Association, in cooperation with Chicago organizations of Negroes engaged in the professions associated with medical care, have clearly stated their position concerning the medical program of the Interdepartmental Committee in a pamphlet entitled "A Plea for a Square Deal in the Administration of Medical Care in America." In its general outlines these organizations agree with the statement of the special session of the House of Delegates of the American Medical Association. However, they lay special emphasis on the fact that the program submitted by the Interdepartmental Committee tends to perpetuate some phases of racial discrimination. They ask that any action under recommendation II providing for the expansion of hospital facilities take note that the most significant shortage in hospital services is in the care for the Negro. Emphatic opposition is offered to "any system of compulsory health insurance."

The following comment under recommendation V—Compensation of loss of Wages During Sickness, is strikingly applicable to much of the discussion of the lack of medical care:

Widespread education of the public must be so strong as to make the people want and will to be healthy. Health cannot be bought; it cannot be given; it cannot be forced upon a people. It must be everlastingly worked for. The basis of health lies in proper habit of eating, sleeping, recreation, clothes and sanitation of home and work of shop. Disregard of any of these elemental fundamentals regardless of all the medical care in the world brings physical disability. Health is not a commodity; it is a condition achieved through individual education and effort maintained by social cooperation. To us it seems that if care depends on the highly trained technical medical profession cooperating with not dominated by society.

## OFFICIAL NOTES

ANNUAL CONGRESS ON INDUSTRIAL  
HEALTH*First Annual Meeting Held in Chicago Jan 9 and 10 1939**(Continued from page 550)*

DR H H KESSLER, Newark, N J, in the Chair

TUESDAY JANUARY 10—MORNING

Health and Safety Activities of the Federal  
Bureau of Mines

MR DANIEL HARRINGTON Washington D C The organic act establishing the Bureau of Mines was approved May 16 1910 The act was amended in 1913 Both the original and amended acts indicated that health and safety of the mine workers constituted the chief function of the bureau Soon after the creation of the bureau an arrangement was made with the United States Public Health Service by which doctors of that organization could cooperate with engineers of the Bureau of Mines in investigations to improve the health of persons engaged in the mining and allied industries The bureau also employed doctors through the civil service, but about 1914 a fairly definite arrangement was made with the Public Health Service At first the health work of the bureau was largely making surveys The first study on a definite problem was in 1914 by Dr A J Lanza and Edwin Higgins on silicosis in the Joplin Missouri region, followed in 1916 by a similar study in the Butte, Montana region by Dr Lanza and Daniel Harrington In 1916 to 1920 field studies on dust and ventilation were conducted in coal and metal mines in mining localities in several states by engineers and doctors under the general direction of Mr Harrington In 1920 the position of chief surgeon was created and Dr R R Sayers of the United States Public Health Service was appointed after which the health work of the Bureau of Mines was devoted largely to the laboratory, though some field activities were continued The Health Division as such was created in 1926 as one of the divisions of the Health and Safety Branch with Dr R R Sayers in charge and laboratory work was done with gases and dusts The work of the Health Division was recessed in 1933 when the funds of the Bureau of Mines were seriously curtailed and was resumed in a limited way in 1935 with Dr H H Schrenk in charge as chief chemist The bureau has no legal authority to enter mines or other establishments or to enforce its recommendations as to health, safety or efficiency, the regulation of mining and other mineral industries being vested in the individual forty eight states rather than in the federal government

The Health and Safety Branch of the Bureau of Mines is essentially a service organization though considerable research is done The branch now has ninety nine persons in its two divisions eighty-two (twenty-nine safety instructors twenty-eight engineers eighteen clerks and seven others) in the Safety Division and seventeen in the Health Division Members of the personnel of the Safety Division are stationed in seventeen states and do field work in nearly every state in the Union The seventeen persons in the Health Division are stationed in Pittsburgh and in Washington D C In its educational activities the engineers and safety instructors of the Safety Division annually come in contact with about 300 000 persons in the mineral industries The first and training work constitutes in some ways the most effective method of putting health and safety data before the mining industry about 100 000 now taking the course annually It is estimated that through it at least 200 lives are saved annually and that probably at least 10 000 nonfatal accidents are prevented During the past fiscal year first aid training was given in 790 mining communities in thirty eight states 102 698 persons receiving certificates for having completed the course

In general the mine worker in reasonably well conducted mines has almost ideal conditions as to temperature and humidity The underground temperature at working places is usually around 60 F with relative humidity around 80 or 90 per cent In most mines the temperature of the working

places varies little throughout the hour, day, week or year, though there are exceptions Many deep mines have high temperatures, others have both high temperature and high humidity, and the workings of shallow mines are very likely to be affected by outside climate conditions, including also to some extent winds

Coal mines generally have far better ventilation systems than are found in other types of underground operations Most coal mines have fairly effective ventilating systems and the chemical quality of the air is usually excellent Ordinarily the oxygen content of the air of coal mine working places is over 20 per cent and carbon dioxide is less than 1 per cent Every year, however, the Bureau of Mines finds scores of instances in which air in working places of supposedly well ventilated coal mines has oxygen below 20 per cent and carbon dioxide above 1 per cent or even as high as 2 or 3 per cent Methane rarely is found in excess of 1 per cent in coal mine working places

The air in metal or nonmetallic mineral mine working places is more likely to be deficient or contaminated than in coal mines Neither the state laws nor considerations of protective expediency usually force them to install efficient ventilation systems

By far the greater number of underground workers have dry surroundings in which to labor The dry working places have both good and bad features The much more pleasant working conditions in dry places carry with them far more health and safety hazards to the underground worker than do the wet places The wet place may merely have water or mud on the floor, or water may fall through the air like rain, varying from a drizzle to a downpour In certain lead ores the water may carry lead compounds in solution and lead poisoning may affect the worker Under some conditions in copper mines copper salts are dissolved in the water and the worker has what are termed "copper sores," and unless his feet are well protected from the water they may become too sore for walking Where the water and air are cold, the worker is likely to be subject to respiratory trouble or he may have rheumatism In wet mines having high temperatures the worker is likely to be afflicted from time to time with boils or to become weakened from too profuse perspiration or from undue heart strain and in wet mines in climates with really cold winters, unless extraordinary precautionary measures are taken the workers are likely to suffer undue exposure in wet clothing on coming to the surface Thus while those in wet places in mines have some health hazards they are likely to escape the scourge to which nearly every underground worker in dry mines or even in dry places in wet mines is subject namely the dust hazard In wet coal mines the worker has relatively little fear of the widespread coal dust explosion nor does he need to fear that his lungs may become incapacitated through breathing finely divided dust particles in the air

After more than twenty years of study of the engineering phases of dust disease in mining, I am of the opinion that breathing large quantities of relatively finely divided dust over long periods ultimately will be harmful to health This includes not only silicious dust but also bituminous or anthracite coal dust or dust of iron ore limestone alumina or any other mine dust or any or all combinations of those dusts Moreover, the dust problem at least in and around mines both as regards health and safety in coal mining and as regards health in noncoal mines should be almost entirely an engineering and operating problem It now is used largely as a type of racket in which the victims of dust disease get little or no relief financial or otherwise yet the mine operators are harassed by lawsuits or foolish regulations Moreover well meaning but poorly informed law making bodies or investigation committees promulgate regulations or laws on dust disease, chiefly with reference to silicosis when no definite data are available as to numerous essential factors With decidedly limited knowledge of the actual underlying facts concerning the causation of dust disease the only safe method of handling the problem at present is to accept the ideas that the long, con-

tinued breathing of air containing large quantities of finely divided dust will almost certainly sooner or later have harmful physical effect and that the only known "cure" is the prevention or limitation of the occurrence of dust in mines. Dust disease is the greatest health menace to the miner, and many of our miners are obliged to breathe far too much fine dust. The outstanding remedy for this bad situation is education of mine workers in the necessity of taking such precautions as are available, of mine officials to recognize the seriousness of the situation and to provide equipment and methods to reduce or prevent the incidence of disease and, if necessary, to force their adoption on the miners, of the doctors to correctly diagnose dust disease, give publicity to its prevalence, its seriousness, and to preventive remedies, and in death certificates to assign miners' consumption of other dust disease as the cause when such is the case, and of the merchants, newspapers and other influences in the community in trying to prevent the disease rather than in hiding its existence.

The introduction of rock dust into coal mines to prevent or limit explosions is a long step in the right direction toward coal mine safety and, if done with judgment, need not introduce any additional health hazard into coal mines.

Sanitation in and around mines has been improved, but much remains to be done before the miner or his family can be said to work or live under up-to-date sanitary conditions. Sewerage conditions in general may be termed deplorable. In coal mines any attempt to remedy conditions as to sewerage would be ridiculed by the workers as childish, though metal miners are inclined to react with some favor to rules or devices looking to improvement of underground sewerage conditions. The mines, with some exceptions, have not had sufficient assurance of stability of operation to justify the expenditure for really good sanitary conditions in mining communities; this includes sewers, city water system, concrete roads, lawns, brick or concrete houses with baths and other conveniences. Many fairly progressive mines have failed to provide a good usable type of wash house, though some mining companies have wash houses or "drys" that resemble palaces. Very likely it would not only pay well in the various kinds of satisfaction they bring to those who work in mines but also in dollars and cents if the companies would do far more than they have done to provide workers and their families better welfare and sanitation facilities.

As specific remedial measures for metal mines I would suggest mechanical ventilation, with some definite person in charge, to force moving currents of air to every place where men work to remove dust, heat and gases. The use of water should be enforced in every place where dust may be found. Where possible, the blasting should all be done after a shift, where this cannot be done there should be enforcement of strict regulations as to the wetting of the region of blasting both before and after the shots are fired, removal of all explosive fumes by adequate air currents, and prevention of entrance into a blasted place until all dust and fumes have been removed. There should be strict physical examination of mine workers before employment and at periods of not greater than six months during employment, with prompt removal from dangerous underground work should unfavorable physical symptoms be found.

The coal mining public, instead of 'standing pat' and referring to out of date and often misleading foreign statistics that coal dust is harmless to health, should make an impartial, strict study of dust conditions in coal mines, paying particular attention to examination of the chest conditions. Coal camp doctors who have direct knowledge of the harmfulness of coal dust to underground workers should come forward with technical articles descriptive of the situation, and state and federal authorities and other interested agencies should cooperate in making studies and publishing results as to the health situation of workers in dusty places in coal mines.

A short paper cannot cover adequately the necessities in trying to evaluate the results and accomplishments of the Bureau of Mines in its health and safety efforts for the benefit of those engaged in the mineral industries. On the safety side some figures are available. During the five year period just previous to the creation of the Bureau of Mines 13,288 persons were killed in the coal mines of the United States,

an average of 2,658 a year, and the fatality rate for this five year period was 5.89 persons killed per million tons of coal produced. The number killed in our coal mines in 1932 was 1,207, and the fatality rate per million tons of coal produced was 3.36, in 1933 there were 1,064 killed, a rate of 2.78, in 1934 there were 1,222 deaths, a rate of 2.93, and in 1935 there were 1,242 deaths, a rate of 2.93, tentative figures for 1936 indicate that 1,330 fatalities occurred, a fatality rate of 2.72, the lowest coal mining fatality rate on record, and tentative figures for 1937 show that there were 1,467 fatalities, a rate of 2.98. During the twenty-seven years of the Bureau of Mines, the coal mine fatality rate has been reduced sufficiently to indicate an average annual saving of life of more than 1,000 persons. If the cost of a life to the operator is considered at a relatively low amount, such as \$5,000, irrespective of humanitarian considerations (and not considering nonfatal accidents) the annual saving of somewhat more than 1,000 lives may be considered as 'worth' more than \$5,000,000, or almost three times the amount being expended by the Bureau of Mines during the present fiscal year and nearly double the entire expenditure of the bureau for any year of its existence.

The financial losses that the workers have avoided through this increased safety of coal mine operation are colossal. The average age of the coal mine worker who is killed is about 35 years and, in general, he should have a future active working period of at least twenty years. In normal times he should earn at least \$1,000 annually, in his twenty years' active life expectancy he would receive approximately \$20,000 for his services. Hence the saving of the life of about 28,000 coal mine workers in the past twenty-seven years through a decreased death rate in coal mining has prevented a financial loss to them of at least \$560,000,000, and this does not take into consideration the financial losses saved to the worker through the elimination of large numbers of nonfatal accidents.

The foregoing detailed facts about coal mining are more or less similar to safety conditions in the other phases of mining and allied industries, including metal mines, nonmetallic mineral mines and the petroleum industry, all of which still have a relatively high rate of accident occurrence, though much progress has been made in the past six years.

The beneficial effects of the health work of the bureau can by no means be as readily shown statistically as can the effects of its safety work, but definite information can be given not only as to the effect on workers but also as to protective or preventive methods, devices and procedures. The work of the bureau with respiratory protective equipment is outstanding, its early work in dust constitutes the basis of information and teaching on these matters today in industrial work, numerous other accomplishments of a fundamental character could be mentioned. The subject of health in mining, however, has not been given nearly the attention it warrants. It is almost certain that far more underground workers are incapacitated or die annually from the breathing of excessive amounts of dust than are killed by mine explosions and fires. Air conditioning, now practically in its infancy in general industry, offers a possible fruitful means of safeguarding the health and to some extent the safety of the mine worker. A few mining companies are making air conditioning installations. When mine disasters with loss of life occur or when mine workers become incapacitated or die from ill health resulting from their occupation, much of the burden finally falls on the public, as cost is ultimately passed on to the user of coal or other mineral products. In addition, while the compensation received by the victims or their dependents help them temporarily, in general the families of crippled or killed miners or the sickly or crippled miners themselves, become largely dependent on the public for support, in one manner or another. Health and safety work in mining and allied industries offer large remuneration in salvage of life and limb as well as in dollars and cents for dividends as well as for capital investment. Questions in connection with occupational disease are harassing industry and mining is deeply affected, suits involving millions of dollars have been in court in connection with dust disease, and this is only the beginning. The prevention of dust disease in mining is readily susceptible of solution and its various ramifications should be attacked vigorously. The Bureau of Mines is the best agency to handle the research

Numerous other health and safety problems in the mining and allied industries also can and should be solved, and again the Bureau of Mines is the logical organization to do much of the work. The bureau, with its vast experience and with a definite record of accomplishment, is the spark plug to keep the work functioning effectively, but to enable the Bureau of Mines to do a good job, the funds allotted to it for health and safety work should be increased severalfold.

### The Public Health Interest in Industry —Federal, State and Local

DR WARREN F. DRAPER, Washington, D. C. The health of about 20 million people who are engaged in productive occupations and on whom the life and health of much of the population depend is of paramount concern to those entrusted with the welfare of the nation. It is well known that certain environmental factors such as poisons, dusts, excessive temperatures and humidities, defective lighting and noise have a decided influence on the health of workers. There is evidence indicating a greater average mortality rate in the industrial population than in the group of gainfully employed persons as a whole. A high mortality is especially notable among unskilled workers. Workers in large establishments are provided with health services to some extent, but the provision of health services in small establishments is a more difficult matter.

In considering health improvement we are confronted with several problems. First, the disability and loss of time due to occupational accidents still bulk large in the layman's view of industrial hygiene. According to the last preliminary report of the National Safety Council there were 19,000 deaths in 1937 due to industrial accidents. Second, certain occupations are associated with high morbidity and mortality. Thirdly, many workers in early adult and late life are found to lack the physical capacity and mental stamina to undertake certain types of work. Lastly, we have far too much absence from work due to sickness. While accidents, occupational diseases and high occupational death rates appear to be impressive, there is no doubt that the least dramatic side, the lost time and incapacity due to illness is important. Large industrial establishments have expanded their medical services to include such functions as preemployment and periodic physical examinations of workers, job placement and medical and engineering control of occupational diseases. At present forty-six states have laws providing benefits in the event of accidental injury and twenty-one of these have enacted legislation compensating workers for one or more occupational diseases. During the past year several states have had commissions studying their occupational disease problems for the purpose of guiding the legislatures in their consideration of occupational disease legislation.

The United States Public Health Service, through its Division of Industrial Hygiene, has been active for years in this field with reference to research, education and cooperative service. Today there are twenty-five state industrial hygiene units actively engaged in this work, while six other states are conducting studies for the purpose of determining their needs with reference to such a program. All but six of these units were established within the last two years. According to data supplied by the U. S. Department of Labor the direct and indirect costs of industrial injuries in this country are approximately 5 billion dollars annually. This estimate does not include the economic losses due to nonindustrial injuries and illnesses which we know are far in excess of specific occupational diseases and accidents. The twenty-five industrial hygiene units in the states and the federal government are spending approximately 1 million dollars. The wide difference between the economic loss and the amount spent for prevention indicates forcefully the need for greater effort for the protection and improvement of the health of the worker.

Experience has shown that in the practice of industrial hygiene the essential features of a program should include research and its application, and education. The machinery for carrying out such a nationwide program is already in existence. The Division of Industrial Hygiene has been conducting research both in the laboratory and in the field and the results have been disseminated throughout the nation to be

applied by the appropriate agencies. In addition, the Division of Industrial Hygiene has been active in the development of industrial hygiene services in state and local organizations, so that conditions affecting the health of our industrial workers may be properly appraised and steps taken for their improvement.

Under an enlarged program of the Public Health Service for industrial hygiene the work naturally divides itself into three categories. First, the administrative functions concerned with coordinating all activities undertaken by federal and state agencies and by unofficial organizations. Second, the expansion of industrial hygiene units in state and local health departments. Finally the studies and investigations carried on by the laboratory and field sections of the Division of Industrial Hygiene.

The work of the division is to be carried out cooperatively with state and local health departments, industry, physicians and unofficial organizations concerned. The chief functions of a division of industrial hygiene in a state department of health are to study factors adversely influencing the health of workers, to control unhealthful conditions and to integrate all the facilities within the department of health and the state which can produce an improvement in the health of workers.

The determination of the scope and nature of the industrial hygiene problem should be the first consideration, and this will indicate the kind, magnitude and direction of the work to be undertaken in this field. It would be possible to make this determination in any state where reliable statistics are available on industrial morbidity and mortality, and accurate information on occupational diseases and accidents. At present such data are lacking in nearly all the states; in some instances information on accidents exists, and less frequently on occupational diseases. The preliminary survey now in progress indicates that already sickness records are kept on nearly half of our working population. It is felt that, by intensive educational work among physicians and industrial officials, arrangements can be effected to secure reports of absenteeism due to occupational diseases and other illnesses. The Division of Industrial Hygiene has been receiving such data for many years from a group of thirty industrial sick benefit organizations which provide sickness benefits for approximately 170,000 industrial workers. The methods for expanding this plan on a nationwide basis are therefore available. The success of a nation's industrial health program is dependent on the standard and completeness of the health services that are provided for industrial workers. While the treatment of traumatic injuries and the performance of physical examinations on applicants for work are necessary, industrial medicine can no longer be considered to be limited to these activities alone. Modern practice requires the application of preventive measures as well. A plan for providing health services in industry should include:

#### A Under the direction of the plant physician

- 1 Regular appraisal of plant sanitation
- 2 Periodic inspection for occupational disease hazards
- 3 Adoption and maintenance of adequate control measures
- 4 Provision of first aid and emergency services
- 5 Prompt and early treatment for all illnesses resulting from occupational exposure
- 6 Reference to the family physician of individuals with conditions needing attention, cooperating with the patient and his physician in every practical way to remedy the condition
- 7 Uniform recording of absenteeism due to all types of disability
- 8 Impartial health appraisals of all workers
- 9 Provision of rehabilitation services within industry
- 10 The conduct of a beneficial health education program

#### B Under the state or local bureau of industrial hygiene

- 1 Consultation with plant management regarding needed corrections of environmental conditions
- 2 Advice to the management and medical supervision as to the relative toxicity of materials or process and advice concerning new materials prior to their introduction into the industry
- 3 Assistance in developing, maintaining and analyzing an effective record
- 4 Consultant service to medical supervision or private physicians, compensation authorities and other state agencies regarding illness affecting workers
- 5 Provision of necessary laboratory service of both a clinical and a physical nature
- 6 Integration of the activities of other public health bureaus in their programs for worker—for example, the control of cancer, syphilis and tuberculosis

To determine the best methods of controlling occupational disease and reducing illness caused by the industrial environment, laboratory and field investigations must be carried on constantly. There is a need for the determination of the toxicologic effects of inorganic and organic substances used in industry, especially new commercial compounds. For example, the development of organic solvents is increasing so rapidly that new solvents are being evolved for potential and industrial use almost every day. An evaluation of the toxic properties of such substances should be made before their commercial application in order to prevent harmful effects to the workers using them. The employment of new commercial compounds has increased the number of cases of industrial dermatitis. We must devote time to this problem, especially with regard to methods of determining the effects of materials on the skin, methods of treatment, and the development of preventive measures for control.

There is need for investigating radiation phenomena with particular reference to their effect on the spread of air borne infections, to industrial smoke pollution as a factor in health and to the determination of injury and physical changes arising from the industrial use of x-rays and radioactive materials. Studies have been requested in the field of vibration, noise and illumination. Industrial hygiene must be prepared to develop methods of measuring physical fitness under various industrial conditions such as high and low temperatures and humidities, rarefied and compressed air, and certain conditions in which repeated motion and strenuous activities are concerned. Finally, the determination of methods for controlling exposure and reducing occupational disease hazards through engineering methods is a problem which has received inadequate attention. Fundamental work on methods and equipment needed for the control of dust, fumes, vapors and gases so that concentrations may be reduced below the threshold limits is one of the most important functions of industrial hygiene. The Public Health Service has received requests for assistance in the way of money and of teaching personnel. Since in further promoting a satisfactory health program the needs for trained personnel will grow, it is important that institutions for clinical research and the teaching of industrial medicine be established as early as possible.

#### Industrial Health Activities by Labor Departments in the Government

DR ALICE HAMILTON, Washington, D. C. The subject given to me is the part played by the federal and state departments of labor in the protection of workers against accident and disease. The federal government for many years did not concern itself with industrial health and the Division of Labor Standards, the branch of the Department of Labor now concerned with it, is of very recent origin. While it is simply an advisory body, the function of the Division of Labor Standards is very important. Its duty is to formulate codes of safe procedure which the states may adopt and to frame model laws which the states may, if they choose, enact. This means a great deal of fact finding and of consultation with experts in many fields.

A labor department thinks first of the practical aspect of the problems of industrial health, or the way in which the actual worker in the actual factory or mine is to be protected against the dangers which experts have discovered. In this country the greatest obstacle to good practice in this field is lack of trained factory inspectors. The English factory inspector is a college graduate, considers his position one of dignity and importance, and has permanent tenure. One of the great aims of the Division of Labor Standards is the training of factory inspectors, and in its brief life the division has held four regional schools for factory inspectors. The first one was in Baltimore under the auspices of the Johns Hopkins University School of Medicine. Inspectors from Virginia, West Virginia, North Carolina and Tennessee attended. We had lectures in the morning and visits to factories in the afternoon. We tried to show them where the danger was. The other schools have been held in Pennsylvania and in two groups of Middle Western states. In addition, the Division of Labor Standards has prepared four page leaflets which tell the effects of poisons and dusts, the mode of prevention and the proper treatment.

The working out of codes in cooperation with the American Standards Association and with the Public Health Service is another duty of the Division of Labor Standards. The great problem facing the division at the outset was silicosis. The Division of Labor Standards had as its duty the prevention of silicosis by proper engineering devices, the discovery of such devices and their application in industry. This was the starting point for the four committees on silicosis which made up the National Silicosis Conference, committees of experts in medicine, in engineering, especially ventilation engineering, in the economic and insurance phases of the problem, and in regulation and law enforcement. An important part of the work of the division is rendering special service to the state labor departments many of them fairly new in this work. When I go to Washington, I am asked to take part in a conversation with some labor official faced with a problem with which he does not know how to deal. The division can give him advice and lend him the services of an industrial hygienist with practical industrial experience with ability to make air analyses and to test ventilating apparatus.

Much information comes to the division through its connection with labor concerning dangers in certain occupations. Some of this is erroneous, the men making wrong conclusions from what they see. Much of this information from workmen has a real basis and complaints and compensation claims on the part of workers have brought to light many more industrial dangers than have ever been revealed by physicians' reports. In every state and, so far as I can find, in every industrial country the effort to get doctors to report cases of occupational disease has been unsuccessful. It was the complaints of employees that revealed the toxic action of tetra-ethyl lead, of luminous paint of manganese and of many of the newer solvents. It is for the Division of Labor Standards to listen to the reports of trade union officials and to sift out the facts or to initiate an inquiry which will bring out the facts and show whether or not the workers' fears are justified. I remember in the old days in the rubber industry, when aniline and aniline derivatives were the chosen accelerators, that I was skeptical of complaints from the heat vulcanizing end. I thought the danger was in the compounding room and in the mixing mills. Then the chemist showed me how chemical reactions taking place under the influence of the heat would result in the production some times of aniline, sometimes of aniline derivatives and even of mustard gas.

Thirty years ago the first start was made in this field by the federal government, but the activity of the state governments is of much more recent development. Even now only a minority of the forty-eight states have made a beginning. Very few have worked out a capably functioning division of industrial hygiene and yet it is only in the states that this work can be practically done. The federal government may help in the establishment of such units but it is the state that must run the unit. The best state organization in the country is that of New York State. In 1936 there were more than 1,900,000 factory employees in that state. There were 457,516 accidents reported and 1,500 cases of occupational disease. The department has a personnel of thirty-four: six doctors, eight engineers, seven chemists, five safety men and eight clerical employees. It has a library and its own laboratory. It is expected to inspect and pass on all ventilation equipment, to make chemical analyses of all unknown materials to carry on routine inspections of factories and special inspections on the basis of complaints from workers, and to do research work on problems of dusts and poisons. The relation to the actual factory inspection service is very close yet the physicians connected with the department do carry on research in the dusty and poisonous trades. We must all remember their bulletin on lead poisoning based on the careful examination of 1,480 lead workers, their bulletin on carbon monoxide, and recent articles on ethylene glycol monomethyl ether, methanol acetate, trichlorethylene, and their reports on silicious dusts. The great advantage the department in New York has is that the results of such research are at once the property of the law enforcing and code formulating units of the department, and that the research may be initiated at the request of the nonscientific division when suspicion has been aroused in factory inspection with regard to certain processes in an industry. This is an important point. An indus-

trial hygiene unit should have the closest possible connection with the department whose responsibility is the protection of the health of the workers.

The Labor Department of New York receives a complaint from a trade union that conditions in a certain plant are such as to cause sickness among the workers. The factory inspector reports that a certain new solvent is used there, and the people think it makes them sick. He does not know what the solvent is or whether the sickness is caused by it. The labor department in such a case should question the industrial hygiene unit, and the latter should be ready and able to respond by sending engineers and chemists to determine the hazard and physicians to make a study of the illness. The industrial hygiene unit may be more interested in research than in its application to industry, but the results of its research will be of little value unless they are passed on promptly to the enforcing branch. Imagine a factory in which the personnel department and the medical department work independently of each other, where the doctor might observe a disproportionate number of cases of disability coming from one department but would not inform the personnel management and request an inquiry to determine the cause. Such a system would be considered inefficient. The industrial hygiene unit of the state should be the consultative aid of the Department of Labor.

One function of the New York Department of Labor is to help in settling workmen's compensation claims. This is objectionable to most industrial hygienists, and they seek to avoid any traffic with these controversial matters. Indeed, I believe that in Connecticut the law creating the industrial hygiene bureau in the department of health specifically states that the bureau may not be called on to give help in compensation suits. I cannot see that that is a reasonable stand to take. Compensation suits are far too much in legal hands already. Such a method throws them still more into the hands of the lawyers and the doctors selected by them and makes an impartial decision more difficult. The claimant and the insurance company must be allowed to have their medical experts, but then there should be an appeal to an impartial expert, and where should one look for him except in a governmental body? I sympathize with men who are reluctant to subject themselves to the treatment that lawyers, alone among civilized men, think it proper to deal out to their fellow men if they happen to be on the other side, but I do not see how the branch of the state government that is entrusted with the problems of industrial accidents and diseases can wash its hands of this kind of expert service.

#### The Activities of Independent Agencies in the Field of Industrial Health

DR W. J. McCONNELL, New York. Independent agencies engaged in industrial health work may be classified into general groups of private foundations and national associations, universities, trade associations, insurance carriers, industrial and mercantile establishments and labor groups.

The Air Hygiene Foundation of America, Inc. is a non-profit organization supported by the industries and dedicated to the advancement of industrial health through the study of occupational diseases. Research projects and studies supported by the foundation are in progress at a number of institutions. The foundation has surveyed medical, engineering and legal phases of current occupational disease problems and has developed an exhaustive bibliography and data file on occupational diseases enabling the organization to serve as a clearing house of information on the subject. Abstracts of current occupational disease literature are issued monthly. Three professional committees—medical, preventive engineering, and legal—each composed of specialists in their particular fields are maintained by the foundation.

The American Association of Industrial Physicians and Surgeons was organized in Detroit twenty-four years ago. Scientific exhibits of interest to the industrial physician are features of the annual meeting. A committee has under consideration a field survey of plant dispensary equipment to determine to what extent plant medical equipment can be standardized and what are the approximate costs of adequately equipping plant dispensaries of various sizes.

The American College of Surgeons does excellent work through its Committee on Industrial Medicine and Traumatic Surgery.

The American Medical Association has always published in THE JOURNAL information in the field of industrial health, but emphasis was given the subject a decade ago through the organization of the Section on Preventive and Industrial Medicine and Public Health. The Association authorized in June 1937 the organization of a Council on Industrial Health as a standing committee of the Board of Trustees. The Council was organized in December 1937 and has developed a working organization through the appointment of a secretary and the creation of official committees.

The American Public Health Association for twenty-five years has engaged in the study of a wide variety of public health subjects through the Industrial Hygiene Section, which is one of ten sections of the association.

The American Society of Heating and Ventilating Engineers, through its research laboratory, for a number of years has been conducting studies on the effects of high temperatures and various humidities on workmen. The laboratory recently has studied the reactions of different groups of office workers to air conditioning. A committee of the society is engaged in a study of high humidities such as are found in the textile industries. A joint committee of the society and of the American Society of Refrigerating Engineers has drawn up a code of recommended minimum requirements for comfort air conditioning. Another committee of the society and the U. S. Weather Bureau are conducting a study at the present time for the purpose of establishing weather design factors which may be useful in the design and operation of air conditioning systems.

The American Standards Association is a federation of national associations and governmental departments. It serves as a clearing house through which industrial, technical and governmental groups develop and coordinate their standardization programs in the interests of economy, looking forward toward the development of a single consistent set of national standards. It is the recognized national standardizing agency. Any organization with standards which it feels would be more effective if approved as American standards may present its standards to the association for approval. This association initiates projects in the field of industrial health only when a specific request has been received and after the request has been investigated and approved by the standards council of the association. About 400 standards and safety codes have thus far been approved. The association is developing a safety code for work in compressed air. A code on electroplating is in draft form. The association's reports on 'Fundamentals Relating to the Design and Operation of Exhaust Systems' was the first document of its kind to be prepared. Other subcommittees have been organized to develop standards for rock drilling, grinding, buffing and polishing and similar subjects with particular relation to the use of exhaust systems. An important activity in the field of industrial health is the work of the Sectional Committee on Allowable Concentrations of Toxic Dusts and Gases.

The Illuminating Engineering Society was organized in 1906 for the advancement of the theory and practice of illuminating engineering. Its chief contribution to the field of industrial health lies in its code of lighting for factories, mills and other work places. This code has been officially approved as an American standard by the American Standards Association. The society is engaged at the present time in preparing good lighting practices for specific industries.

The National Safety Council is interested primarily in industrial and public safety. The council's booklets 'The Healthy Worker' and 'Safeguarding Women in Industry' have had wide distribution. The National Safety Act is a monthly paper carries an industrial health section.

The National Tuberculosis Association, through a number of local organizations, have included at one time or another, among other activities, an industrial health program.

The Saranac Laboratory for the Study of Tuberculosis undertakes research studies sponsored by the Trudeau Foundation. They are coordinated with clinical, roentgenologic and engineering field studies in industries in which dust and tuber-

culosis constitute an occupational hazard. Animal experimentation is used to test hypotheses formulated from field data to explain peculiar manifestations of disease and their causation. The problems of study at present fall into two groups, one which concerns the effects of dust alone and a second in which alterations in susceptibility to tuberculosis are of primary interest. While field investigations of certain industries are conducted for the confidential information of those concerned, the many research studies issued by the laboratory and addresses by the members of the laboratory staff are given wide circulation.

The Industrial Health Conservancy Laboratories was established on a fee basis to serve industry in all health problems relating to workers and working conditions. Organized in 1920, it is the oldest privately maintained organization of its kind in the United States. Its field of activity has covered such subjects as industrial intoxications, occupational diseases, industrial hygiene, industrial epidemics, medical organization and authoritative testimony. Three types of services are offered to industry: membership services, retainer services and special and miscellaneous services. The organization issues a booklet describing these services and kindred matters.

Among the independent agencies which are not only conducting research and field investigations in the industrial hygiene field but are offering courses of instruction in industrial hygiene to students and graduates are a number of the universities in every section of the country.

The American Foundrymen's Association's efforts in the field of industrial health are directed toward the development of good practices for the foundry industry and the collection of information helpful in formulating codes for the industry. The Industrial Hygiene Codes Committee of this organization has so far published three good practices reports and is engaged in preparing others.

The National Association of Manufacturers Committee on Healthful Working Conditions recently organized is interested for the present in the coordination of the best practices in industrial medicine in an effort to adapt them to the varying types of manufacturing plants, and the 'selling' of good industrial practices to the industrialists of the country.

The Portland Cement Association has conducted an anticold campaign among the employees of member plants and at present is providing funds for a dust-health study of the cement industry.

Another group of independent agencies actively interested in the promotion of industrial health work is the insurance group. A number of the compensation carriers maintain a laboratory of industrial hygiene for the study of existing industrial health hazards and of measures for controlling them in the plants of the industries which they insure under their workmen's compensation policies. A partial list at least of the compensation companies maintaining industrial hygiene laboratories are the Aetna Life of Hartford, Conn., the Employers Liability of Boston, the Employers Mutual Liability of Wausau, Wis. (laboratory at Milwaukee), Fidelity and Casualty of New York, Liberty Mutual of Boston, Maryland Casualty of Baltimore, Michigan Mutual Liability of Detroit, Travelers of Hartford, Conn., and the Zurich General Accident Liability of Chicago.

The largest group of independent agencies whose activities in the field of industrial health are directed particularly toward safeguarding the health of workmen is the employer group. The duPont organization has erected an institute known as the Haskell Laboratory of Industrial Toxicology, the staff of which determines the toxicity of the many chemical products manufactured by the organization and recommends safe methods of employing them in industrial processes. The Union Carbide and Carbide Chemical Corporation recently has begun a study of the toxicity of some of its products. Many other organizations have established industrial hygiene laboratories for the study and prevention of health hazards encountered in their respective plants. These services are all supplementary to well rounded health programs carried out in each subsidiary of the corporation. Unique features of the medical program of the American Telephone and Telegraph Company are the general health course and the nutrition course for women with certain follow-up activities and the course in safety and first aid for men.

Emphasis is placed on the development of proper health habits conducive to the maintenance of good health and to practical everyday methods of living.

Labor organizations, as a group of independent agencies, appear rather backward in any sustained efforts in the field of industrial health. Attempts have been made by labor organizations to promote health programs, but for some reason best known to themselves these programs were discontinued. A notable exception is the health service rendered by the Union Health Centre to its members. This organization for twenty-five years has acted as the Health Department of the International Ladies Garment Workers Union. With the exception of a single grant of \$20,000 from the Roscnwald Fund, the Union Health Centre has been supported from fees from its members. In 1934 it became an integral part of the International Union.

The group of independent consultants in industrial health is composed of eminent industrial physicians and engineers whose services are available to industrial organizations large or small, that may require consultation service.

#### DISCUSSION ON GOVERNMENTAL INTEREST IN INDUSTRIAL HEALTH

DR CARTER: I want to ask a question about the publishing of these papers. Are you going to publish them in THE JOURNAL or in a bulletin?

DR H. H. KESSLER, Newark, N. J.: They will be published in THE JOURNAL.

DR CARTER: I think we should have a bulletin.

DR KESSLER: In New Jersey there are several medical agencies that are interested in the field of industrial health. We have a Committee on Industrial Health in the state medical society and a new branch of the American Association of Industrial Physicians and Surgeons has been developed. The governor has called a conference on medical care and it is through that conference that a subcommittee on industrial health has been formed. These three groups, and still another group, the New Jersey Sanatorium Officers Association are interested in industrial health and they will have an opportunity for expressing their points of view on certain state programs and governmental programs that will be developed. As Dr. Draper described, and also Dr. Hamilton, the federal government is interested in establishing programs of industrial hygiene throughout the country and so far twenty-five states have adopted this program under the auspices of the state department of health. In New Jersey this program has not yet gotten under way because of opposition of the state department of labor to the establishment of such a program under the auspices of the state department of health.

MR. LOUIS RESNICK, New York: Dr. McConnell overlooked one national health agency in New York, and that is the National Society for the Prevention of Blindness. The society has a very small industrial relations department and has published a book entitled "Eye Hazards in Industrial Occupation, a handbook for state engineers and industrial executives. It is now revising the book and will bring out a new edition in the spring. It has also made a study of eyes saved in industry, in cooperation with the National Safety Council. It has published a number of smaller pamphlets, including "The Self Appraisal of Eye Protective Measures" and a so called program for 100 per cent eye protection. It held joint meetings with the National Safety Council and the American Association of Industrial Physicians and Surgeons in Detroit a few years ago. Those who are interested may write to the National Society for the Prevention of Blindness and get a complete list of its industrial publications. Most of them are available for free distribution.

DR. A. S. LEVY, Chicago: Dr. McConnell pointed out the various independent agencies that have been doing splendid work in trying to increase the health of the worker and the health conditions in industry. He pointed out that the greatest group responsible for this phase of work was the employers' group, also that the least groups are the insurance carrier and working groups. That is a little bit conflicting. From my experience in the field of industry some of the large industrial firms—employers—have done and are doing fine work toward their employees, but the majority of those in the employer group had not been interested greatly with reference to the health of employees or to health conditions in industry until the employees,

governmental agencies and labor groups forced them to take cognizance of the fact. Dr Draper pointed out that there were over 19,000 cases of deafness due to injuries that arose in the course of employment. He pointed out that there were over two million workers exposed to the hazards of dust, there were over one million workers injured and maimed during employment. What good does it do to find a worker suffering from tuberculosis or pneumoconiosis if one is not able to do something for him? What good is it to find a worker suffering from a dermatosis or other conditions when there are no provisions made to take care of him or his family adequately during the course of treatment? The doctor must be considered in this problem. He must be paid for his work. If adequate medical provisions are made with all these problems which were presented for the adequate health protection of industry, we should include also the health and the economic protection of the doctor.

Dr W J McCONNELL, New York. No doubt there are other organizations that I omitted. I regret that I could not give in more detail the work some of these organizations are doing. A number of the directors of those organizations are present and I was hoping that they would perhaps elaborate. I did not intend to give the impression that the insurance carriers were grouped with labor. Perhaps modesty prevented me from emphasizing the excellent work which I think the various insurance companies have been doing in industrial health.

(To be continued)

## RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p m eastern standard time (1 p m central standard time 12 noon mountain time, 11 a m Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis that is the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

February 22	Cancer Can Be Cured
March 1	Diabetes
March 8	Water Waste and Sanitation

<sup>1</sup> Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WENR at 8 p m each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

*Bills Introduced*—H J Res 153, introduced by Representative Sirovich, New York, proposes to authorize the Bureau of Marine Inspection and Navigation of the Department of Commerce and the Division of Marine Hospitals and Relief of the United States Public Health Service to investigate, among other things, the percentage of lascar seamen requiring medical attention in American ports and the number put ashore for hospital treatment. H J Res 162 introduced by Representative Sirovich, New York, proposes to establish an annual award in each of the fields of literature, music, art, drama, journalism, medicine, chemistry, physics and mathematics, to be known as Distinguished Service Medal in Arts and Sciences, to foster and encourage the development of science, art and literature in the United States. H R 2975, introduced by Representative Voorhis, California, proposes to amend the Social Security Act by authorizing an initial appropriation of \$10,000,000 and thereafter for each fiscal year a sum sufficient to carry out the purposes of the bill to enable each state to furnish financial assistance or other assistance including but not limited to medical, dental and mental aid to needy transients. H R 2987 introduced by Representative Reed, Illinois, proposes to compensate any employee of the United States government who shall furnish blood for transfusion to a member or former member of the military establishment who is a patient in a government hospital. H R 3141 introduced by Delegate Dimond, Alaska, proposes to extend the benefits of the United States Public Health Service to persons aboard or operating any vessel in fishing operations. H R 3530 introduced by Representative Marx, Minnesota, proposes to authorize an appropriation of \$650,000 to erect a veterans domiciliary unit to provide 700 beds at Fort Snelling, Minnesota, and to provide the necessary auxiliary structures, mechanical equipment and outpatient dispensary facilities. H R 3578 introduced by Representative Cannon, Florida, proposes to authorize an appropriation of \$1,423,000 to construct a marine hospital in or near the city of Miami. H R 3644 introduced by Representative Bradley, Michigan, proposes to authorize an appropriation of \$700,000 to construct a veterans hospital in or near Gladstone, Mich., with a capacity of 150 beds for the accommodation of veterans entitled to such facilities under existing

law and future law." H R 3700, introduced by Representative Peterson, Florida, proposes to authorize an appropriation of such sums as may be necessary to construct a marine hospital in Florida on a site to be selected by the Federal Board of Hospitalization. H R 3941, introduced by Representative Havenner, California, proposes to authorize an appropriation of \$600,000 to construct a 134 bed patient capacity addition to the existing veterans' facility at Fort Miley, Calif., for the treatment of general medical and surgical disabilities. H R 3951, introduced by Representative Smith, Ohio, proposes to amend the recently enacted federal food, drug and cosmetic act so that a manufacturer or distributor of any nostrum favored by the amendment may be enabled, through mail order diagnoses by physicians employed to make them, to sell his wares throughout the country without complying with the labeling requirements imposed on his less favored competitors. A nostrum to be thus favored, however, is to be such as has been 'not dangerous to health and has been effective in relieving the condition for which it is prescribed in at least 1,000 cases a year during the last twenty years preceding the approval of this act.' H R 3999 introduced by Representative Welchel, Georgia, proposes to amend the Social Security Act so as to provide federal financial aid to states to enable them to assist needy individuals who are permanently crippled to a degree that precludes them from being able to engage in a gainful occupation.

### DISTRICT OF COLUMBIA

*Bills Introduced*—H R 3650 introduced by Representative Guver, Kansas, proposes to prohibit within the District of Columbia the manufacture, importation, exportation, transportation, sale, gift, purchase or possession of any spirituous, vinous, malt fermented and all alcoholic liquors whatsoever which may be used as beverages except natural wine for religious services and ethyl alcohol used (1) for compounding or manufacturing medicines for internal use and (2) by physicians, surgeons and dentists as a disinfectant. H R 3808 introduced by Representative Reece, Tennessee, proposes to provide for the use of scientific tests to determine the degree of intoxication of operators of motor vehicles in the District of Columbia whose vehicle causes personal injury or substantial damage to any other vehicle or property.

## STATE MEDICAL LEGISLATION

## Alabama

*Bills Introduced*—S 13 proposes to require the governing body of each county to appropriate annually a sum equivalent to not less than 20 cents per capita of the population of such county, to be used for the maintenance and operation of a full time county health department. H 155 proposes to appropriate \$50,000 annually for the next two years to provide state aid to the several counties for constructing or expanding county and/or district tuberculosis hospitals. H 164 proposes to eliminate the provisions in the present medical practice act requiring that not less than two examinations of applicants for licensure shall be held annually and to provide instead for the holding of examinations annually.

## Arizona

*Bills Introduced*—H 115, to amend the provisions of the medical practice act, proposes, among other things, that holders of certificates and permits to practice medicine and surgery and holders of certificates and permits to practice osteopathy shall be accorded equal rights and privileges by public institutions, officers, and commissions. H 148 proposes to prohibit the retail sale or distribution of any device, appliance or medical agent used in the prevention of venereal disease except by licensed physicians and by licensees of the State Board of Pharmacy.

## Arkansas

*Bill Passed*—H 92 passed the house, February 3 proposing that nothing in the dental practice act shall prohibit or prevent any licensed physician from extracting teeth in an emergency when he shall deem it advisable and when a licensed dentist is not reasonably available.

*Bills Introduced*—S 143 and H 252 propose as a condition precedent to the issuance of a license to marry, that both parties to a proposed marriage present certificates from licensed physicians that they have submitted to physical examination, including a Wassermann and/or Kahn blood test, and a dark field test where indicated, and that, in the opinion of the physicians the parties either are not infected with syphilis or are not in a stage of that disease which may become communicable. House 252 was reported favorably to the House January 31. S 41 and H 222 propose to provide for the payment of compensation to workmen injured in the course of their employment and to require an employer to supply an injured employee with necessary medical, hospital and nursing care. Under both bills an injured workman must accept the physician tendered by the employer, and only if the employer fails or neglects to provide a physician may an injured workman select a physician of his own choice. Neither bill proposes to provide compensation for disability resulting from occupational diseases. H 220 proposes to repeal the existing laws relating to sale and disposition of food and drugs and to enact a uniform food, drug and cosmetic act. S 194 proposes that, whenever in a civil or criminal proceeding issues arise on which the court deems expert evidence desirable, it may appoint one or more experts, not exceeding three on each issue, to testify at the trial. The fact that such experts have been appointed by the court is to be made known to the jury. S 223 proposes to enact a retail sales tax law and to impose a tax of 2 per cent on the gross proceeds derived from sales of tangible personal property. The bill specifically provides that the tax shall apply to "All sales made by physicians, surgeons, optometrists, oculists, opticians, veterinarians, dentists or any other person engaged in rendering personal and professional service in which any tangible personal property is sold or consumed." H 287 proposes to enact a new cosmetic therapy or beauty culture practice act which purports to permit licensees among other things, to remove superfluous hair from the body of any person by the use of the hands, mechanical or electrical apparatus or by the use of cosmetic preparations or antiseptics. This bill was reported favorably to the house on February 7. H 335 proposes to prohibit the operation of a hospital unless licensed by the State Welfare Board. The

board is to be authorized to revoke the license of a hospital having "sanitary conditions and professional conduct" contrary in its opinion to the best interests, safety or welfare of the people. The bill specifically provides that "The standard of ethics as adopted by the American Hospital Association is hereby adopted as a standard by which any hospital in this state shall operate."

## Georgia

*Bills Introduced*—H 190 proposes to strike out those provisions of the medical practice act which require that five members of the Board of Medical Examiners be regular physicians, three to be eclectic physicians and two to be homeopathic physicians. This bill was reported favorably to the house, February 10. H 238, to amend the law permitting the organization of corporations to operate nonprofit hospital service plans, proposes that "at least a majority of the directors of such a corporation must be at all times directors, superintendents or trustees of hospitals which have contracted or may contract with such corporation to render its subscribers hospital service, or a Board of Trustees which shall be approved by the Insurance Commissioner."

## Idaho

*Bill Passed*—S 71, to amend the medical practice act, passed the senate February 3 and the house February 9, proposing, in effect, to permit students who have had training in recognized medical colleges in good standing and who are performing the duties of an intern in any duly organized hospital operating under the supervision of a medical staff freely to perform their duties without being licensed to practice medicine.

## Indiana

*Bills Introduced*—S 173 and H 291 propose to enact a self-styled Uniform Indiana Food, Drug, and Cosmetic Act, to regulate the sale and distribution of foods, drugs, cosmetics and therapeutic devices. H 34 proposes to impose a tax of 1 per cent on the gross income from professional services.

## Iowa

*Bill Introduced*—H 120, to amend the chiropractic practice act, proposes that a license to practice chiropractic "shall authorize the holder thereof to practice chiropractic and to use light, heat, air, water, diet and exercise in the treatment of disease, but shall not authorize the licensee to practice operative surgery, obstetrics, x-ray therapy, or administer or prescribe any drug or medicine included in materia medica."

## Kansas

*Bills Introduced*—H 147 and S 171 propose extensive amendments to the osteopathic practice act. Most important, both bills propose that an osteopath is to have the right "to practice osteopathy in all its branches, which includes operative surgery with instruments, physiotherapy and the use of drugs, as taught and practiced in the legally incorporated colleges of osteopathy of good repute and the right to register under the laws of the United States of America governing narcotics."

## Maine

*Bills Introduced*—H 708 proposes to require osteopaths to renew their licenses annually, to pay an annual fee of \$2, and to condition annual renewal on the presentation by each licensee of satisfactory evidence that he has attended in the preceding year at least two days of the annual "educational" program conducted by the State Osteopathic Association, or its equivalent. H 931 proposes to make stated persons residents of Portland, a body corporate to be known as The Associated Hospital Service of Maine, whose purpose is to establish, maintain and operate a non-profit hospital service plan, whereby hospital care may be provided by hospitals or groups of hospitals with which this corporation has a contract for such purpose to such of the public as become subscribers to said plan under a contract which entitles each subscriber to certain hospital care.

### Massachusetts

**Bills Introduced**—S 396 proposes that no lumbar or spinal puncture shall be made on any patient or inmate of any state institution unless previously thereto a signed written assent is obtained from the patient. H 1401 proposes that no person be required to submit to vaccination or inoculation as a condition precedent to admission to any public school or other institution nor to the exercise of any right, performance of any duty, or enjoyment of any privilege. Any person who vaccinates or inoculates a child, or an adult under guardianship without the written consent of parent or guardian is to be subject to a fine of \$100 or imprisonment for a year or both. H 1407 proposes, in effect, to limit licensure to practice medicine to citizens of the United States or to persons indicating their intention to become such by filing first papers. The bill, however, is not to prevent the board of registration in medicine from permitting foreign specialists to practice in the state for any period the board permits. H 1535 proposes to permit the Department of Public Welfare to establish and maintain health clinics in cities of more than 50,000 population. H 1543 proposes, before a person under complaint or indictment for crime can be committed to a hospital for the insane, that he or she shall have the right to be examined at the expense of the state by two physicians of his own choice. H 1778 proposes to require factories to maintain, in addition to the first aid appliances now required, "the services of a registered nurse for the treatment of persons injured or taken ill upon the premises." H 1827 proposes to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit such sample to an approved laboratory for a standard serologic blood test for syphilis. H 1828 proposes, as a condition precedent to the issuance of a license to marry, that both parties to a proposed marriage present physicians' certificates showing that a blood examination of both parties has been made within ten days separately and individually in which a serological complement fixation or flocculation test was made at a regularly approved laboratory and that both tests have been negative for syphilis. A marriage license may issue if any party fails to present the certificate just referred to if he or she presents a physician's certificate that the party has been Wassermann fast during a period of three years and has received not less than forty arsphenamine injections and not less than fifty heavy metal injections. The bill also provides that A test for gonorrhea shall be requested of both applicants for marriage license but this examination shall be voluntary only on the part of the female and may be waived by her if she refuses such an examination. H 1489 proposes that whenever a medical question is in dispute in any case the court may appoint a duly qualified impartial physician to appear and testify and may allow him for so testifying a reasonable fee and necessary traveling expenses. H 1432 proposes to impose an annual occupational tax of \$5 on all persons practicing any profession in the state. S 326 proposes to make it unlawful for any person attached in any capacity to any hospital or sanatorium to aid an attorney to solicit a retainer or other authority to perform legal services for any person confined in the hospital or sanatorium. H 1898 proposes a system of compulsory and voluntary sickness insurance the benefits of which are to consist of cash and all forms of medical dental and hospital services. Persons covered by the Massachusetts unemployment compensation law are included in the compulsory insurance of the bill. All other persons may elect to participate in the voluntary insurance. H 1643 to amend the workmen's compensation act proposes to permit an employer to obtain policies of workmen's compensation insurance excluding from their coverage any or all medical and hospital services and medicines. An employer procuring such a policy is to be solely liable for the obligation excluded.

### Missouri

**Bills Introduced**—H 111 to amend the osteopathic practice act proposes to provide that The system method or science of treating diseases of the human body commonly known as osteopathy and as heretofore or hereafter taught and practiced by colleges of osteopathy recognized and approved by the Missouri

State Board of Osteopathic Registration and Examination, is hereby declared not to be the practice of medicine and surgery within the meaning of the medical practice act. S 29 proposes to require all applicants for licenses to practice any form of the healing art, as a condition precedent to the right to examination and licensure by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology to be given by a board of examiners in the basic sciences which the act proposes to create.

### New Hampshire

**Bill Introduced**—H 291 proposes to repeal existing laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act. Narcotic drugs, as defined by the bill, are to include coca leaves cannabis, opium and every substance neither chemically nor physically distinguishable from them.

### New York

**Bills Introduced**—A 500 proposes to enact an entire new insurance code. Among other things, the bill contains provisions authorizing the organization of corporations to operate on a nonprofit basis plans either (1) for medical expense indemnity or (2) for hospital service, but not both. Medical expense indemnity, the bill proposes, is to consist of reimbursement for medical care provided through duly licensed physicians and for nursing service and the furnishing of necessary appliances, drugs, medicines and supplies. A 523 proposes to authorize the supplying of all forms of medical, surgical, dental, hospital and nursing care to the public at large without cost by persons in the employ of the department of health. All licensed practitioners of medicine, dentistry, pharmacy and nursing who submit to the provisions of the bill and practice as directed by the department are to receive an annual compensation from the state of up to \$6,000. The bill proposes that the administration of these services be vested in four new divisions to be created in the State Department of Health and that the department exercise exclusive charge and control over all of the public hospitals of the state and exercise complete supervisory powers over all private hospitals. The department is to have power to build or acquire medical supply depots, medical laboratories, hospitals, dispensaries and sanatoriums. A 762 proposes to require any person arrested on suspicion of driving a motor vehicle while intoxicated to submit to examination by a licensed physician designated by the appropriate county or city medical society. The examination must be made within two hours after arrest and is to include coordination and blood or urine tests. A 771 proposes to create a temporary state commission to investigate and analyze the nature and extent of mental disorders and defects, to determine the relationship between mental ailments and crime or criminal tendencies and the legal responsibility and punishment of persons who are mentally sick, for crimes committed by them. A 784 proposes to require a physician treating a case of cancer or other malignant tumor to report the facts to the appropriate health officer. A 794 proposes to enact a separate chiropractic practice act and to create a board of chiropractic examiners to examine and license persons to practice chiropractic. "The practice of chiropractic" the bill defines as the science of locating and the removing of nerve interference in the human body according to chiropractic principles where such interference is indicated or misalignment or subluxations of the vertebral column appear. It excludes operative surgery, prescription or use of drugs or medicine or the practice of obstetrics. A 801 proposes to limit the issuance of licenses to practice medicine dentistry nursing professional engineering and architecture to citizens of the United States. A 340 to amend the law granting hospital liens for services rendered in caring for persons injured through the negligence of another proposes that the fee for filing a claim of lien in the counties comprising the city of New York shall be 50 cents and that the fee for filing a discharge of lien in those counties shall be \$1. S 344 proposes to authorize boards of education to provide children who attend schools other than public with all or any of the health and welfare services and facilities including but not limited to health, surgical, medical,

dental and therapeutic care and treatment, and corrective aids and appliances, authorized by law to be provided children in the public schools. The bill also proposes that the Board of Education in a city may provide for physically handicapped children transportation, home teaching, special classes or special schools, scholarships in nonresidence schools and, on recommendation of the state department of health, surgical, medical, dental or therapeutic treatment, hospital care crutches braces and other supplies. A 569, to amend the insurance law and the membership corporation law in relation to nonprofit health service plans, proposes to authorize the organization of corporations to operate a nonprofit health service plan, including complete medical, surgical and hospital care, to such of the public as become subscribers to the plan. A 737, to amend the medical practice act, proposes to make it an additional ground for suspension or revocation of a license for the holder thereof (1) to have been guilty in any way of unprofessional conduct, or (2) to have advertised by any means for patronage. A 614 proposes to create a temporary state commission to study the dental needs and requirements of the inhabitants of the state and to collect data and statistics looking toward the establishment of a long range state supervised dental program. A 755 proposes to amend the hospital lien act, which specifically gives any person or corporation legally liable for the lien the right to examine hospital records in this matter, but also giving this right of examination to the injured person or his legal representative, in case of death. A 756 proposes to amend those provisions of the medical practice act making it a ground for the revocation or suspension of a license to practice for the holder thereof to advertise for patronage by means of handbills posters circulars, letters stereoptical slides, motion pictures newspapers, radio or magazine but proposes also a similar penalty for advertising for patronage by newspapers.

#### North Dakota

*Bills Introduced*—H 154 proposes to prohibit the operation of maternity homes and hospitals or institutions with maternity beds unless licensed by the State Department of Health. H 170 proposes to deny tax exemption to any hospital "wherein any physician and surgeon who holds a valid and unrevoked license to practice his or her profession in the state is denied the right and opportunity to fully use and enjoy the facilities thereof." H 226 proposes to require all applicants for licenses to practice any form of the healing art, as a condition precedent to their right to examination and licensure by their respective professional boards to pass examinations in anatomy, chemistry, physiology, pathology and bacteriology to be given by a board of examiners in the basic sciences. The board is to consist of one physician and surgeon, one chiropractor, one osteopath and two other members "who shall be of good education in the basic sciences and not engaged in the practice of medicine, osteopathy, chiropractic, or otherwise professionally practicing for a fee for the public in the diagnosis of disease or the treatment of human ailments."

#### Oklahoma

*Bills Introduced*—S 17 proposes to authorize the state commissioner of health to appoint one regularly licensed physician for each county in the state to give medical treatment free of charge to such persons as make affidavit that they are unable to pay for such medical treatment. Such physicians are to be paid from \$150 to \$200 a month may not engage in the private practice of medicine, are to be furnished an automobile by the state and are to receive drugs, medicines, bandages and medical equipment on requisition to the state commissioner. Such physicians are not to perform major surgical operations, which must be performed at the state hospitals. H 131 proposes as a condition precedent to the issuance of a license to marry that both parties to a proposed marriage present a physician's certificate that they are free from syphilis and gonorrhea.

#### Oregon

*Bills Introduced*—H 89, to amend the medical practice act proposes, among other things, (1) to permit the Oregon State Medical Society to nominate, for appointment by the governor, persons it desires to serve on the Board of Medical Examiners, (2) to require the Board of Medical Examiners to meet for the

examining of applicants on the second Tuesday, Wednesday and Thursday in January and the third Tuesday, Wednesday and Thursday in June at Portland, (3) to define "unprofessional dishonorable conduct," which is a ground for the revocation of a license, as "such conduct as would not be indulged in by an ethical physician and surgeon, under all the circumstances taking into consideration the good of the patient and public, the time and place", (4) to require applicants to have had at least two years' premedical education in an approved college or university, to have graduated from a medical school or college on the approved list of the Council on Medical Education and Hospitals of the American Medical Association, and to have completed an internship of at least one year in a hospital approved for internship by the American Medical Association, (5) to make it a ground for revocation for a licensee to make false or misleading statements regarding his skill or the value of his medicine, treatment or remedy in the treatment of any disease or other abnormal condition of the human body or mind or to advertise or hold himself out to treat diseases or other abnormal condition of the human body by any secret formula medicine, method, treatment or procedure, (6) to specify in detail the procedure the board must follow in revoking or suspending a license, and (6) to provide that if a person is found guilty of a misdemeanor under the medical practice act a second time it will be mandatory on the court to sentence him to the county jail for not less than ten days, in addition to whatever other fine or imprisonment is permitted by the act. S 187 proposes to make it a felony, punishable by imprisonment in the state penitentiary for not less than two nor more than five years to provide supply or administer to any pregnant woman any medicine or drug, or substance, or to use any instrument or other means whatsoever with intent to procure miscarriage, unless necessary to preserve life.

#### Pennsylvania

*Bill Introduced*—H 161 proposes to require every physician treating or examining any person suffering from or affected with any communicable, infectious or contagious disease to report the facts to designated health authorities. The bill proposes to make it the duty of the respective health authority to whom the reports are made to remove the persons so reported from private residences and other places to the county hospital or to a state institution providing suitable care. The expense of hospitalization and isolation is to be paid by the diseased person or persons liable under existing laws for his support but if these persons cannot pay such expenses then the care must be rendered and charges made to appropriate districts in accordance with existing law.

#### Texas

*Bills Introduced*—H 10, to amend the medical practice act proposes, in effect, to permit persons to apply or use the principles, tenets or teachings of their church in the ministrations to the sick or suffering by prayer without the use of any drug or material remedy and to charge fees for so doing. H 191 proposes to authorize the organization of corporations to establish and operate nonprofit hospital service plans whereby hospital care may be provided by the corporations to their subscribers through established hospitals and sanatoriums with which the corporations may contract for such care. This bill was reported favorably to the house, Feb. 6. H 195 proposes extensive amendments to the chiropody practice act. Among other things the bill proposes to define a chiropodist as one "who shall treat or offer to treat or diagnose any disease or disorder or any physical deformity or injury, or pathological case or ailment of the human foot, by any system or method either medical, surgical, mechanical manipulative or massage physiotherapy, mechano-therapy, electrical appliance or any other system or method." The bill specifically proposes to prohibit a chiropodist from amputating the human foot, toe or toes or from administering any anesthetic other than local. S 74 and H 148 to amend the medical practice act propose among other things, (1) to limit licensure to citizens of the United States, (2) to prohibit the issuance of a license without examination to the holder of a foreign license if the jurisdiction issuing that license does not afford a similar privilege to Texas licensees, (3) to require

an applicant for licensure after examination, in addition to existing educational qualifications, in effect, to have two years of premedical college work, (4) to eliminate the provisions permitting the issuance of a license to practice obstetrics alone, (5) apparently, to permit a Christian scientist to charge for his services so long as he does not maintain an office for treating the sick, (6) to add several causes for the revocation, suspension or refusal of licenses, including "The use of any advertising statement of a character tending to mislead or deceive the public, and 'Advertising professional superiority, or the performance of professional service in a superior manner'", and (7) to penalize unlicensed practice by a fine of from \$100 to \$500 and/or imprisonment up to thirty days. The present law imposes a fine of from \$50 to \$500 and imprisonment up to six months. H 144 proposes to create a State Department of Hospitalization and Medical Care to provide hospitalization and medical care for the indigent sick and indigent expectant mothers. H 176 proposes to prohibit the operation of a hospital unless licensed so to do by the State Hospital Board, which the bill proposes to create. H 204 proposes to appropriate \$150,000 to the State Health Department to aid and assist the organization and operation of full time county health services. H 245 proposes to authorize the board of county commissioners of any county having a population of more than 30,000 to establish and operate a hospital or sanatorium for the treatment of tuberculosis. Hospitals or sanatoriums established under the bill are to be subject to inspection by the state health officer and to such rules and regulations as the State Department of Health may promulgate with respect to them. H 312 proposes to establish a separate naturopathic practice act and to create an independent board of naturopathic examiners to examine and license persons to practice naturopathy. The bill alleges that

Naturopathy is self-definitive to the same extent as are the terms 'Medicine' and 'Osteopathy' and is the science and art of diagnosing and treating disease by the Natural Methods, such as dietetics, fasting, heliotherapy, hygienic and corrective exercise and psycho-therapy, and the physical methods, such as mechano therapy, massage, neurotherapy, spondylopractic hydrotherapy, thermotherapy, electrotherapy and phototherapy, non-surgical obstetrics and the bio chemical methods such as the use of phytotherapy and the use of foods, vitamins, non-poisonous herbs, roots, barks, seeds, fruits, flowers, vegetable oils and plants containing the tissue-building elements found in the normal body, and hygiene, sanitation and first aid as taught in the chartered and legally authorized schools and colleges of Naturopathy and as shall be taught in these schools and colleges in the future." The bill further states that "The term 'Naturopathic School' shall include any school, by whatever name, teaching Naturopathy under such names as Naturopathy, Natural Therapeutics, Physiological Therapeutics, Physcultopathy, Sanopractic, and the term 'Naturopath' shall include the graduates of these schools." This bill was reported favorably in the house February 8.

#### Utah

**Bills Introduced**—S 85 proposes to prohibit the operation of a maternity hospital unless licensed by the state board of health. S 180 proposes that in any action in which the mental or physical condition of a party is in controversy the court may order the party to submit to a physical or mental examination by a physician designated by the court. S 177 proposes to authorize the organization of corporations to maintain and operate nonprofit hospital and medical service plans whereby hospital and medical care may be provided to such of the public as become subscribers to the plan.

#### Washington

**Bill Passed**—H 58 passed the house January 25 proposing to require every pharmacy or drug store to keep in a suitable book or file the original of prescriptions compounded or dispensed therein and preserving them for not less than five years.

**Bills Introduced**—H 100 to amend the workmen's compensation act proposes to make compensable some twenty-one stated occupational diseases. S 31 to abolish the office of coroner in class A and first, second and third class counties and to vest all the powers and duties of that office in the prosecuting attor-

ney, who is to be authorized to employ licensed physicians, when necessary, to assist him in carrying out the duties formerly performed by the coroner. S 77 proposes that whenever in a civil or criminal proceedings issues arise on which the court deems expert evidence desirable, it may appoint one or more experts, not exceeding three, to testify at the trial. The fact that an expert has been appointed by the court is to be made known to the jury. H 199 proposes to authorize employers to enter into written contracts with third persons for providing their employees with medical and surgical treatment, nursing, hospital services or other services or care contingent on sickness or injury not covered by the industrial insurance law or medical aid act and to collect or retain a portion of their employees' wages for that purpose. H 209 proposes to authorize the organization of corporations to conduct a so-called hospital association business. Such corporations are to be authorized to contract with individuals, families, employees, associations, societies, or with employers for the benefit of employees, for the furnishing of medicines, medical or surgical care and attention, nursing, hospital care, ambulance, dental service or any other service contingent on sickness or accident. Such corporations must obtain a license from the insurance commissioner, must have a paid up unimpaired capital of not less than \$25,000 invested in the same manner as is required by law for the investment of capital stock of domestic insurance companies, must file with the insurance commissioner a bond to guarantee the performance of its contract and shall be subject to examination by the insurance commissioner. H 4 proposes to enact a so-called "Basic Therapy Act," which undertakes to make it "unlawful for any person authorized to practice [any form of the healing art] to practice any method of healing or to use any means of treating any disease, injury, deformity or condition of health which was not taught by his respective school, college or university at the time he graduated therefrom, unless he has taken post graduate work therein or has done special research work in connection therewith or has made a thorough study thereof, in which case he is authorized to practice and use the same."

#### West Virginia

**Bills Introduced**—S 18 proposes to amend and reenact the narcotic drug act enacted in 1935. Among other things the bill proposes to classify cannabis as a narcotic drug and to subject its use to the restrictions imposed by the bill on other narcotic drugs and to eliminate a section in the present law, which would by inclusion of cannabis as a narcotic drug no longer seem necessary, forbidding the retail sale or distribution of cannabis except on the written prescription of a physician, dentist or veterinarian. S 107 proposes to authorize the organization of corporations to operate nonprofit hospital service plans under which hospital care is to be provided by a hospital or a group of hospitals with which such corporations contract, to such persons as become subscribers to the plans. H 156 proposes to make a physician incompetent to testify in any legal proceeding, without his patient's consent, concerning any communication made to him by the patient necessary to enable him to prescribe and treat the case. H 183, to amend the chiropractic practice act, proposes, among other things, to define chiroprody, or podiatry, as "the diagnosis of foot ailments, the dressing, padding and strapping of the feet, the making of models of the feet and the palliative, medical, surgical, manipulative, electrical and mechanical treatment of functional disturbances of the feet as taught and practiced in the schools of chiroprody recognized by the public health council." The bill proposes to prohibit licensed chiroprodists from using the title "Doctor" without the designation "Chiroprodist" or "Podiatrist."

#### Wisconsin

**Bill Introduced**—A 195 proposes to direct the State Board of Control to establish a chiropractic ward at the Winnebago State Hospital for the Insane in which patients of that hospital or other state hospitals for the insane may secure chiropractic service. The management and control of the proposed ward is to vest in a licensed chiropractor who is to be responsible to the Board of Control only. The chiropractor referred to must be paid a salary equal to the salary paid the medical superintendent of the institution.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

### ARKANSAS

**State Health Conference**—The Arkansas State Board of Health conducted its annual health conference at Little Rock, Dec 5-6, 1938. The speakers included:

Dr. Allen W. Freeman, Baltimore: Present Tendencies in Rural Health Organization  
Miss Katherine Lenroot, Washington: D. C. Health Needs for Mothers and Children  
Dr. Felix J. Underwood, Jackson: Miss A. Mississippi County Program of Maternal Care  
Dr. Eugene L. Bishop, Chattanooga: Tennessee Administrative Problems in Maternal Control  
Dr. William Dekleint, Washington: D. C. Working Problems Between Health Departments and the Red Cross

### CALIFORNIA

**Society News**—Dr. Charles A. Dukes, Oakland, discussed 'The Voluntary Health Insurance Plan of the California Medical Association' before the San Diego County Medical Society January 20. Dr. Dukes addressed the Los Angeles County Medical Association January 19 on 'Progress Report on the Prepayment Insurance Plan, and Dr. Gösta Dohlman, Lund University, Lund, Sweden, 'State Medicine in Sweden'.

**Cancer Display at Exposition**—An elaborate exhibit showing the many possible causes of cancer has been designed for the San Francisco Golden Gate Exposition. The display is under the supervision of Chauncey D. Leake, Ph.D., professor and head of the department of pharmacology, University of California Medical School. Dr. Alton R. Kilgore, San Francisco, of the California Cancer Commission, and Milton Silverman, Ph.D., director of the Hall of Science of the exposition.

**Personal**—Calvin B. Bridges, Ph.D., known for his work on heredity, died in Los Angeles Dec. 27, 1938, aged 49. Dr. Bridges was active in research on the chromosome theory of heredity and sex determination. He had been a member of the staff of the Carnegie Institution since 1919 and had recently worked at California Institute of Technology, Pasadena.—Dr. Aaron J. Rosanoff, Los Angeles, member of the Los Angeles County Lunacy Commission since 1923 has been appointed director of state institutions, effective January 2. Dr. Rosanoff is a charter member and former president of the Southern California Academy of Criminology.—Dr. Norman F. Sprague, Los Angeles, has been appointed a member of the state board of health, succeeding Dr. George H. Kress. San Francisco, now secretary of the California Medical Association.

### COLORADO

**Annual Registration Due Before March 1**—Every licensee of the State Board of Medical Examiners of Colorado is required by law to register annually, before March 1 with the secretary-treasurer of the board and to pay a fee of \$2 if a resident of Colorado or \$10 if a nonresident. Failure to pay this fee within the time stated automatically suspends the right of a licensee to practice while delinquent. If he nevertheless continues to practice, he is subject to the penalties provided by law for practicing medicine without a license. Failure to pay this fee for three consecutive years results in the automatic cancellation of a delinquent practitioner's license to practice.

### DISTRICT OF COLUMBIA

**Building Program at Gallinger Hospital**—A building expansion program has been made possible at Gallinger Municipal Hospital, Washington, by a WPA grant. The project will include a medical ward building, tuberculosis building, hospital power plant, addition to the nurses home and district morgue, the architecture of all to be in accord with the type now existing at Gallinger. The medical ward building will be six stories high with a capacity of 300 beds and has been planned to care exclusively for internal medicine, leaving the present ward building for surgical cases. The tuberculosis building with a capacity of 225 beds will have five stories. It will care for the local tuberculosis load all of which is now being handled in temporary or obsolete buildings. A three story structure is planned for the nurses' home, adding thirty-nine single rooms.

### FLORIDA

**Changes in Health Officers**—Dr. Kolbein K. Waering, Quincy, health officer of Gadsden County, has been appointed in charge of the Duval County health unit, which has recently been placed on a full time basis. He will be succeeded in Gadsden County by Dr. Irving E. Simmons, who has been supervisor of district number 2 with headquarters in Jacksonville. Dr. William H. Ball, Tampa, has been appointed director of the recently organized health unit in Franklin and Gulf counties.

**Personal**—Dr. Henry Hanson, formerly state health officer and now on the staff of the Pan American Sanitary Bureau in Guayaquil, Ecuador, was recently decorated by the Ecuador government with the Order of Merit recognizing his services in connection with bubonic plague.—Dr. Terry Bird Tavar, has resigned as director of the Lake County Health unit to become executive secretary of the Florida Crippled Children Commission, with headquarters in Jacksonville. Dr. Bird graduated at Tulane University of Louisiana School of Medicine, New Orleans, in 1925.

**New County Society**—The Franklin-Gulf County Medical Society was organized at a meeting in Apalachicola recently with Dr. Chapman I. Dukes Carrabelle president, Dr. Augustus E. Conter, Apalachicola vice president, and Dr. Albert L. Ward, Port St. Joe, secretary-treasurer. Constitution and by-laws were adopted and a formal application was signed by the following charter members: Drs. William H. Ball, Apalachicola; Lule H. Barte, Port St. Joe; Thomas Meriwether, Wewahatcha; James R. Norton, Port St. Joe, and the officers.

### GEORGIA

**The Block Memorial Lecture**—Dr. Myrtelle M. Cannon, curator of the Warren Anatomical Museum, Harvard University Medical School, Boston, will deliver the fifth annual Bates Block Memorial Lecture at the Academy of Medicine Atlanta, February 23. His subject will be 'Changes in the Spinal Cord in Mental Disease and Defect'.

**Winners of the Fischer Awards**—The annual L. C. Fischer Award of the Fulton County Medical Society was presented to Dr. William A. Smith for the best written paper. His work was entitled 'Periodic Paralysis: Report of Two Fatal Cases: Review of the Literature.' For the paper showing the best original research the award went to Drs. Emmet D. Colvin and Rudolph A. Bartholomew. Their paper was entitled 'Behavior of the Basal Metabolism in the Course of Developing Toxemia of Pregnancy: Correlation with Cholesterol, Placental Infarcts and Retinal Examination: Study of 62 Consecutive Adolescent Colored Primigravidae.' Every member of the society is eligible to compete for these prizes. Since 1925, when Dr. Luther C. Fischer established the prizes consisting of \$100 each, they have served to stimulate the members of the society in preparing better papers. Case reports, clinical talks or papers may be submitted.

### ILLINOIS

**Outbreak of Scarlet Fever**—A quarantine was placed on Concordia Teachers College, River Forest, January 31, on account of three cases of scarlet fever among the students; twelve students were under observation. Other students are attending classes but must avoid contacts with the public; newspapers reported February 4. Fifty day students were forbidden to go to classes.

**Society News**—Dr. Delmas K. Kitchen, Detroit, discussed 'Diagnosis and Treatment of Gonadal Immaturity' before the Peoria City Medical Society January 17.—At a joint dinner meeting of the La Salle and De Kalb county medical societies in Ottawa Dec. 3, 1938, Dr. Jay Arthur Myers, Minneapolis, discussed tuberculosis.—At a meeting of the Madison County Medical Society in Alton January 6 Dr. August A. Werner, St. Louis, spoke on the menopause.

**Health Department Sponsors Educational Programs**—The first Southern Illinois Regional Conference was held in Harrisburg January 17-19 under the auspices of the state department of health. The conference was one of a series now being held in districts throughout the state. Mediums of reaching the public include health exhibits, talks and motion pictures. The first conference was held in Aurora in the fifth district, which embraces seventeen counties. A similar assembly convened in the tenth district including Logan, Mason, Cass, Menard and Sangamon counties.

## Chicago

**Outbreak of Influenza**—Sharp increases in influenza have been reported in Chicago, newspapers announced February 11. The Lake Forest High School was closed indefinitely February 9, but no action had been taken by the board of education to close the Chicago schools. A survey made by the school board disclosed that 76,547 pupils and 982 teachers were absent February 10 from 648 public and parochial elementary schools. There were 19,326 students and 212 teachers absent from the city's thirty-eight high schools. It was stated that the student absentees were triple the average number. Newspapers reported that the incidence appeared to be higher outside the city limits.

**Branch Meetings**—Drs. George L. Apfelbach addressed the Evanston Branch of the Chicago Medical Society February 2 on 'Fractures of the Neck of the Femur—Causes of Nonunion', Edmund F. Foley, 'Cirrhosis of the Liver', and Thomas C. Galloway and Eustace L. Benjamin, Evanston, Ill., 'Acute Tracheobronchitis'. The North Side Branch was addressed February 2 by Drs. Rudolf Schindler on 'Gastroscopic Studies of Diseases of the Stomach' and Walter L. Palmer 'Clinical Course and Therapy of Gastric and Duodenal Ulcer'. Dr. Fred M. Smith, Iowa City, discussed 'Diagnosis and Treatment of Coronary Occlusion with Particular Reference to Atypical Forms' before the North Shore Branch February 7. At a meeting of the Englewood Branch February 7 Dr. Bernard Fantus spoke on 'Sulfanilamide in Coccal Infections'.

**Graduate Course in Syphilis**—The department of dermatology in the University of Illinois College of Medicine cooperating with other departments will conduct a graduate course in syphilis in the Research and Educational Hospital, 1819 West Polk Street, beginning February 27. The course, offered under a grant from the federal government with the approval of the state department of public health will run eight weeks and consist of lectures, laboratory demonstrations and the presentation of hospital and dispensary clinical material designed to present to the practitioner a review of the subject and discussion of recent developments in this field. The course will be repeated four times a year. Applications together with a check covering the registration fee of \$10, made payable to the University of Illinois should be sent to the examiner and recorder at 1853 West Polk Street.

## IOWA

**Society News**—Dr. John K. Von Lackum, Cedar Rapids, was chosen president-elect of the Iowa Academy of Ophthalmology and Otolaryngology and Dr. Dean M. Lierle, Iowa City, was installed as president, succeeding Dr. Harry H. Lamb, Davenport, at the recent annual meeting. Dr. Byron M. Merkel, Des Moines, was reelected secretary-treasurer. The next annual session will be held in Iowa City in 1939. Cedar Rapids was chosen for the 1940 meeting. Dr. John T. McClintock, Iowa City, discussed 'Present Status of the Physiology of the Gastrointestinal Tract' before the Linn County Medical Society in Cedar Rapids February 9. Drs. Donald R. Black and George H. Thiele, Kansas City, Mo., will address the Des Moines Academy of Medicine and the Polk County Medical Society March 14 on 'Treatment of Diabetes and Clinical Manifestations of Anorectal Diseases and Their Treatment' respectively.

## LOUISIANA

**Special Society Elections**—Dr. William Harvey Perkins, New Orleans, has been chosen president of the Tuberculosis and Public Health Association of Louisiana, succeeding the late Dr. William H. Seemann. Dr. Monroe Wolf was recently elected chairman of the New Orleans Urological Society. Dr. Hugh T. Bertram, vice chairman, and Dr. James S. Davidson, Jr., secretary-treasurer.

**Personal**—Dr. George H. Hauser, New Orleans, has been appointed city bacteriologist, succeeding the late Dr. William H. Seemann. Dr. George F. Roeling has been named superintendent of the City Hospital for Mental Diseases, New Orleans, succeeding the late Dr. Lionel L. Cazenavette. Dr. Joseph Rigney D'Aunoy has been appointed by the Louisiana State University Medical Center to serve as a member of the board of the Guidance Center of the New Orleans Institute of Mental Hygiene. Dr. Frank R. Gomula, by Mayor Macarty and Dr. John H. Musser, by Tulane University of Louisiana School of Medicine.

## MARYLAND

**Professor McCollum Receives Manufacturers' Award**—Elmer V. McCollum, Sc.D., since 1917 professor of biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, recently received the annual award of the Associated Grocery Manufacturers of America for outstanding contributions to the scientific knowledge of foods.

**Society News**—The Baltimore City Medical Society was addressed January 20, among others, by Drs. Lawrence R. Wharton and Charles S. Stevenson on 'Genital Tuberculosis and Pregnancy, with Special Reference to Tubal Gestation'. Dr. James M. H. Rowland, dean, University of Maryland Medical School, Baltimore, reviewed a 'History of the Faculty of the University of Maryland between 1830 and 1870' before the Cordell Historical Society January 11. Drs. Julius Friedenwald and Samuel Morrison, both of Baltimore, recently read a paper before the Maryland Academy of Medicine and Surgery entitled 'Clinical Aspects of Gastrointestinal Hemorrhage'.

## MICHIGAN

**Undulant Fever at State College**—An outbreak of undulant fever at Michigan State College, East Lansing, caused the death of one student and the illness of about twenty-one students and as many residents of East Lansing, according to the *Chicago Tribune* February 4.

**Dr. Vaughan Honored**—Henry F. Vaughan, Dr. P.H., health commissioner of Detroit, was honored at a dinner, January 12, marking his twenty-fifth anniversary as a member of the department of health. Mr. Gustavus D. Pope, a member of the board of health since 1918, was toastmaster. A treatise written in 1561 on 'Health Practices of the Time' was presented to Dr. Vaughan from the department. He also received a leather bound volume containing the signatures of all members of the department and 250 letters from persons known in medicine and public health throughout the country. Speakers at the dinner, attended by 1,025 persons, included Col. Edward D. Rich, former teacher of Dr. Vaughan and sanitary engineer at the Michigan Department of Health. Dr. Reginald M. Atwater, executive secretary of the American Public Health Association, New York. Dr. John T. Phair, chief medical officer of health in Ontario, W. Frank Walker, Dr. P.H., New York, Miss Grace Ross, Detroit, president of the National Organization for Public Health Nursing, Mr. Charles Hughes, Detroit, and Bleecker Marquette, executive secretary of the Public Health Federation of Cincinnati. Guests at the dinner included Drs. Henry A. Luce and Henry Cook, president and past president respectively of the Michigan State Medical Society. Henry R. Carstens, president Wayne County Medical Society. Hugo A. Freund, formerly a member of the city department of health. Harold J. Knapp, health officer of Cleveland, and Fred Adams, health officer of Windsor, Ont.

## NEW JERSEY

**Appropriation for Pneumonia Serum**—The public health committee of the Medical Society of New Jersey recently adopted a resolution urging the legislature to appropriate \$25,000 for pneumonia serum to be used in the treatment of persons unable to afford serum. An appropriation of \$10,000 was made recently but \$2,200 worth of serum was used in one week. The legislature appropriated \$25,000 last year.

**Society News**—Dr. William J. Carrington, Atlantic City, president of the Medical Society of New Jersey, and Mr. William H. MacDonald of the state department of health addressed a meeting of the Fourth Judicial District of the Medical Society of New Jersey in December at Silver Lake Inn near Berlin. Part of the evening was devoted to social activities. Dr. James A. Fisher, Asbury Park, is counselor for the district. Drs. Josephine B. Neal, New York, and Fredric F. Elliott, Brooklyn, addressed the Hudson County Medical Society, Jersey City, February 7 on 'Diagnosis and Treatment of Acute Infectious Diseases of the Central Nervous System in Children' and 'Medical Expense Indemnity' respectively.

## NEW YORK

**Study of Distribution of Physicians**—Dr. Joseph S. Lawrence, Albany, executive officer of the Medical Society of the State of New York, has issued a study of the distribution of physicians in the state, tending to show that physicians and hospitals are available to all areas. The highest ratio of physicians to population was in Livingston County, where there is one physician to 1,298 persons, the lowest in Dutchess County, one physician to 478 persons. Livingston County also

has the highest ratio of general hospital beds to population, one to 1,644, the lowest was in Ontario County, one to eighty-four. The report observes that it must be borne in mind that no county is an isolated unit, so that service of physicians and hospitals of adjacent counties are always available. Improved transportation and communication in rural districts have increased the usefulness of the physician, it was pointed out, but the same conditions have led the rural resident to seek the services of the city physician except for emergencies, and in some instances this trend has induced rural physicians to move to the cities, at the same time retaining their rural practices. The study also showed that improved living conditions are attracting young men to locate in the rural areas and that there is no notable difference in the ages of the men in rural districts as compared with those in urban districts. Among other points, Dr. Lawrence's study suggested that nursing service as part of a public health program demands prompt study.

**Academy Offers Lectures on Obstetrics**—The New York Academy of Medicine announces a series of lectures on practical obstetrics Wednesday afternoons, at 4:30 under the joint auspices of the academy and the Medical Society of the County of New York. The following speakers will appear:

- Dr. Thaddeus L. Montgomery, Philadelphia: The Use of Analgesics in Labor, March 1.
- Dr. Joseph N. Nathanson: Syphilis in Pregnancy, March 8.
- Dr. Howard C. Taylor, Jr.: Principles of Hormone Diagnosis and Theories of Endocrine Therapy in Pregnancy, March 15.
- Dr. James Burns Amberson, Jr.: Management of Pregnancy Complicated by Tuberculosis; and Dr. Edwin P. Maynard, Jr.: Heart Disease, March 22.
- Dr. Albert H. Aldridge: Recognition and Management of Abnormal Presentations, March 29.
- Dr. Edward G. Waters, Jersey City, N. J.: Sulfanilamide and Other Therapy in the Treatment of Postpartum Sepsis, Postpartum Sepsis and Pylitis, April 5.

#### New York City

**The Sir Robert Jones Lecture**—Dr. Arthur Bruce Gill, professor of orthopedic surgery, University of Pennsylvania School of Medicine, Philadelphia, will deliver the Sir Robert Jones Lecture February 23 in the auditorium of the Hospital for Joint Diseases. His subject will be "Treatment of Congenital Dislocation of the Hip."

**Harvey Lecture**—Dr. Edwards A. Park, professor of pediatrics, Johns Hopkins University School of Medicine, Baltimore, delivered the fifth Harvey Society Lecture of the season at the New York Academy of Medicine February 16. His subject was "The Pathology of Rickets with Particular Reference to the Changes at the Cartilage Shaft Junctions of the Growing Bones."

**Society News**—Dr. George P. Muller, Philadelphia addressed the Medical Society of the County of Kings January 17 on "Surgical Treatment of Peptic Ulcer" and Dr. Philip I. Nash delivered his inaugural address as president on "Present Day Problems in Medicine."—Dr. Benjamin Burbank, among others, addressed the Brooklyn Thoracic Society January 20 on "The Acute Abdomen During Pneumothorax Therapy."—A symposium on "Mental Disorders of Modern Times" was presented before the International and Spanish Speaking Association of Physicians, Dentists and Pharmacists January 20 by Drs. Gerald H. J. Pearson and Herbert Freed, Philadelphia, Otto Klineberg, Ph.D., Drs. George W. Henry and Stephen P. Jewett.—Dr. Henry W. Louria delivered an afternoon lecture before the Medical Society of the County of Queens January 20 on "Symptoms in the Treatment of Thyroid Disease."

#### OHIO

**Ohio State Assembly**—The annual Post-Collegiate Assembly of the Ohio State University of Medicine will be held in Columbus March 2-4. The formal scientific program will begin Thursday afternoon March 2 with Dr. Charles A. Doan, professor of medicine, presiding. Dr. John H. J. Upham, dean of the medical school, will preside at a program summarizing research in various departments. Clinical talks by faculty members will be presented Friday morning, followed by round table discussions for the rest of the day. Friday evening Dr. Logan Clendening, Kansas City, Mo., will deliver the annual Alpha Omega Alpha Lecture on "The Doctor in Art, Literature and Music." Guest speakers will present the program Saturday morning at the Deshler-Wallick Hotel as follows:

- Dr. Lowell A. Eri, New York: The Effects of New Drugs in the Treatment of Pneumonia.
- Dr. Arthur W. Thomas, chief bureau of child hygiene, state department of health, Cooperating with the Physicians of Ohio.
- Dr. Joseph A. Johnston, Detroit: Factors Which Affect Growth.
- Dr. Virgil S. Counceller, Rochester, Minn.: Ovarian Neoplasms: Their Pathological and Surgical Significance.

This meeting will be followed by the alumni reunion luncheon, at which Dr. Charles T. Atkinson, Middletown, president of the medical division of the alumni association, will preside. The final session at St. Francis Hospital Saturday afternoon will feature talks by Drs. Leslie Bigelow, Columbus, on his association with the late Dr. Starling Loving, former head of the medical college, and Jonathan Forman, Columbus, on the laying of the cornerstone of the St. Francis Hospital and the Starling Medical College ninety years ago. The committee in charge of the assembly consists of Drs. Upham, ex officio, Russel G. Means, chairman, Jonathan Forman, secretary, historian Charles A. Doan, Verne A. Dodd, Herbert M. Platter, Noel Paul Hudson and Isaac B. Harris.

#### OREGON

**Society News**—The Grants Pass Chamber of Commerce entertained the Josephine County Medical Society at a luncheon meeting Dec. 5, 1938, at which Dr. Clarel L. Ogle, Grants Pass, presented views of organized medicine and Dr. Charles L. Coyle, Grants Pass, recent attempts to control syphilis.—Dr. Hans Lissner, San Francisco, addressed the Central Willamette Medical Society, Eugene, recently on "The Many Fold Indications for and Proper Use of Thyroid Substance."—Dr. John H. Hutton, Portland, addressed the Lane County Medical Society, Eugene, Dec. 16, 1938, on "Newer Methods in Anesthesia."

#### PENNSYLVANIA

**Society Sponsors Poster Contest**—The Medical Society of the State of Pennsylvania will for the second time sponsor a health poster contest among school children. The contests will be managed by the county medical societies and the prize winning posters in the county contests will be entered in competition at the next annual meeting of the state society in Pittsburgh in October. It is believed that the health poster contest tends to bring school children and the family physician into closer contact and gives the children an appreciation of the part played in community health by the county medical society.

#### Philadelphia

**General Ireland Gives Potter Memorial Lecture**—Major Gen. Merritt W. Ireland, U. S. Army, retired, will deliver the William Potter Memorial Lecture at Jefferson Medical College February 23 on "Medicine's Debt to the United States Army." General Ireland was surgeon general of the army from 1917 to 1931.

#### SOUTH CAROLINA

**Personal**—Dr. Wofford E. Baldwin, formerly of Chester health officer of Chester County, has been transferred to Oconee County.—Dr. Henry R. Perkins, Rockmart, Ga., has been appointed health officer of Abbeville and Laurens counties.

**District Society Meeting**—The Second District Medical Association held its annual meeting in Columbia January 26 with the following speakers: Drs. Claude C. Coleman, Richmond, Va., on "Management of Acute Head Injuries"; Paul H. Culbreth Jr., Ellenton, "Congenital Hemolytic Jaundice"; and Lucius Emmett Madden, Columbia, "Coronary Thrombosis."

**Annual Bennettsville Meeting**—The Marlboro County Medical Society held its annual New Year meeting and banquet in Bennettsville January 10. On the scientific program the speakers were Drs. Arthur H. London Jr., Durham, N. C., on "Treatment of Pneumonia in Children"; Joseph Decherd Guess, Greenville, "Some Observations Concerning Practical Obstetric Practice"; Frank K. Boland, Atlanta, Ga., "Diseases of the Colon"; and William H. Kelley, Charleston, "Management of the Anemias." After dinner speakers were Drs. James R. DesPortes, Fort Mill, president, and Edgar A. Hines, Seneca, secretary of the South Carolina Medical Association and Mayor Throop C. Crosland of Bennettsville.

#### TENNESSEE

**Venereal Disease Clinic for Negroes**—A new clinic for care of Negroes with venereal disease was opened in Knoxville recently with Dr. Frank A. Faulkner as director and Dr. Napier A. Henderson, Negro physician, as a assistant. An allotment of \$6,000 from federal funds made the clinic possible.

**Society News**—Drs. Paul H. Dietrich and Jesse B. Swafford addressed the Hamilton County Medical Society at Chattanooga, Dec. 15, 1938 on "Roentgen Consideration of Nontuberculous Chest Lesions" and "Inversion of Sex in trans."

and Its Relations to Insanity" respectively — William B Wendel, Ph D., and Dr James W McKinney addressed the Memphis and Shelby County Medical Society Dec 6, 1938, on "The Clinical Significance of Methemoglobinemia" and "Transplantation of the Cornea" respectively

## VIRGINIA

**Graduate Course in Ophthalmology and Otolaryngology**—The University of Virginia sponsored its fifth postgraduate course in ophthalmology and otolaryngology in the medical school, Charlottesville, December 6-9. The instructors were Drs Clarence H Smith, New York; Chevalier L Jackson Philadelphia; Ebenezer Ross Faulkner New York; Romeo A Luongo, Philadelphia; Harry S Gradle, Chicago; Grady C Clay, Atlanta; and James W White, New York.

**Dr McGinnes Goes to Tennessee**—Dr Goldsborough Ford McGinnes, Richmond director of the bureau of communicable diseases in the state health department for seven years, has resigned to become director of a venereal disease project sponsored by the Tennessee State Department of Health, the U S Public Health Service and the University of Tennessee at Memphis, with the cooperation of Memphis and Shelby County. In addition, he will be associate professor of preventive medicine at the University of Tennessee College of Medicine. Dr McGinnes, who graduated from the University of Virginia Department of Medicine, Charlottesville, in 1925, was health officer of Isle of Wight County for a time. After a year at the Johns Hopkins University School of Hygiene and Public Health he served three years as director of laboratories for the state department of health before appointment to his present position.

## WASHINGTON

**Society News**—Dr Ralph H Loe, Seattle, addressed the Spokane County Medical Society, Spokane, January 9 on gastroscopy. —Dr Karl F Meyer, director of the George Williams Hooper Foundation of the University of California, San Francisco addressed the Walla Walla Valley Medical Society at its annual dinner in Walla Walla, January 12, on "The Animal Kingdom—A Reservoir of Disease". —Dr John Guy Strohm, Portland, Ore. addressed the Cowlitz County Medical Society, Longview Dec 21, 1938, on "Diagnosis and Treatment of Kidney and Bladder Stones". —Drs Souren H Tashian and Roger Anderson Seattle addressed the Lewis County Medical Society, Centuria, Dec 12 1938 on the Gruskin test for malignancy and a new clavicle splint respectively.

## GENERAL

**Dr Hartwell Joins Cancer Society Staff**—Dr John A Hartwell, New York, who recently resigned as director of the New York Academy of Medicine after four years in the position has been appointed associate director of the American Society for the Control of Cancer. He will assume the new work April 1.

**Changes in National Society Staff**—Lewis H Carris, managing director of the National Society for the Prevention of Blindness, New York, assumed the title of general director January 1, with Mrs Winifred Hathaway as associate director. Mrs Eleanor Brown Merrill formerly secretary and an associate director, became executive director.

**Fraudulent Salesman and Repair Man**—From Ohio comes a report of a man calling himself Halsey, offering to repair syringes, surgical instruments and apparatus and taking orders for equipment. One physician placed an order and paid in advance. Several weeks passed without word of the order. The physician wrote to Halsey at his alleged address, Halsey and Company, 1209 Broad Street, Pittsburgh and the letter was returned unclaimed.

**New Health Publications**—The Metropolitan Life Insurance Company announces several new and revised pamphlets which it will supply in limited quantities to social and health agencies and other professional groups in connection with health programs that involve the planned use of literature. The pamphlet "Protecting Your Heart" has been revised with the cooperation of the American Heart Association. "Cold, Influenza and Pneumonia" has been revised with more emphasis on pneumonia. A New Day in Health Protection" is based on the company's motion picture on pneumonia. A New Day

Another publication is "When You Are in Your Teens" directed to growing boys and girls, it contains suggestions for stimulating the appetite and securing the greatest good from food, with outlines of meal plans.

**Indexes for Medical Literature**—Central card catalogs of medical libraries are being made in various cities with the aid of workers provided by the Works Progress Administration. The first of the series of catalogs was launched in Philadelphia, where a catalog of about four million volumes has been established at the Pennsylvania Historical Society. The second was made at Cleveland where the union catalog lists about two million books and is housed in Thwing Hall at Western Reserve University; it includes not only Cleveland libraries but others at the University of Cincinnati, Ohio State University, the University of Michigan and the Clement Library at Ann Arbor, Mich. At Washington, D C, a catalog has been made at the Library of Congress. The latest in the series is in Boston, which will be housed in the Boston Medical Library. It is planned to enlarge the Boston project to include the medical collections in Worcester County.

**Southeastern Surgical Meeting**—The tenth annual assembly of the Southeastern Surgical Congress will be held in Atlanta at the Hotel Biltmore, March 6-8. Among the guest speakers will be

Dr Walter Alvarez Rochester Minn Hints in the Treatment of Gastrointestinal Disease  
Dr William Wayne Babcock Philadelphia Interior Exteriorization in Abdominal Surgery  
Dr Meredith F Campbell New York Urologic Surgery in Children  
Dr Morris Fishbein Chicago Editor of THE JOURNAL Fads and Quackery in Healing  
Dr George W Crile Cleveland Surgical Treatment of Essential Hypertension  
Dr Henry H Kessler Newark N J Rehabilitation of the Physically Handicapped  
Dr Ambrose L Lockwood Toronto Canada, Surgical Life Guards  
Dr Austin A Hayden Chicago Hearing Aids—Old and New  
Dr George Gray Ward New York Uterine Displacements

Dr Irvin Abell, Louisville, Ky, President of the American Medical Association, will deliver the C Jeff Miller Memorial Lecture.

**New Group to Advance Pharmacy as a Profession**—A newly organized Association for the Advancement of Professional Pharmacy held its first open meeting in New York January 24 with Henry V Arny, Ph D, former dean of the Columbia University School of Pharmacy, as the guest of honor. Dr Arny delivered an address on "The Development of the Professional Pharmacy Movement". According to an announcement the constitution of the new association requires members to have a registered pharmacist in charge at all times to refer all requests for advice other than pharmaceutical to a member of the public health profession involved and to maintain the professional appearance of the pharmacy at all times. Among other requirements, members must not maintain food service. Among the purposes of the organizations were listed the following: to educate the public to the dangers of self medication to assist the public to a better understanding of the services of the health professions, to encourage more interest in the prescribing of official preparations and to assist in maintaining uniform standards of requirements and ethics.

**Congress on Obstetrics and Gynecology**—The American Congress on Obstetrics and Gynecology, to be held in Cleveland September 11-15, has announced a preliminary outline of the program. The professional groups that will take part in the congress are those interested in and concerned with the problems of human reproduction, maternal welfare and neonatal care. They include medical, nursing, public health and institutional administrative groups. In the mornings there will be special programs for each organization group and subgroups at noon round table discussions, in the afternoons joint sessions for all members of the congress and in the evenings sessions for all members, with speakers of national prominence. Subjects for the afternoon sessions are announced as follows: neonatal care, plans for prevention and control of uterine cancer, extension education on maternal and neonatal care, economic aspects of maternal care and on the last day a correlation and digest of the proceedings. Evening sessions are outlined: legal aspects of maternity Monday, humanitarian aspects, Tuesday, sociologic aspects Wednesday and ethical aspects, Thursday. The membership fee is \$5 which includes a year's membership in the American Committee on Maternal Welfare. Checks should be made payable to Dr Rudolph W Holmes, treasurer and sent to the headquarters office, 650 Rush Street, Chicago. Both scientific and technical exhibits are being developed.

#### Asthma Research

The report of the Asthma Research Council for the year ended Oct 31 1938, has been published. The research clinic at Guys Hospital reports two noteworthy observations. 1 The results of general treatment without specific treatment are at least as good as the results of general treatment combined with specific desensitization to inhalant proteins and better than those of desensitization alone. 2 There is further evidence of the importance of the psychologic factor, this time in the effects of treating rhinorrhea with physiologic solution of sodium chloride alone. The startling fact was that these were slightly better than those of protein desensitization. Thus the psychologic element was found to be of even greater importance than was anticipated. The conclusion from the five years work of the clinic is that protein desensitization and vaccine therapy have not proved sufficiently successful, but they will be continued to see if the methods can be improved.

On the other hand, desensitization has given satisfactory results at the Asthma Clinic of St Mary's Hospital. It is performed either by self inoculation (the patient being given a set for use at home) or by "rush inoculation" (for which he is admitted to the hospital). The reliability of cutaneous reactions was called in question at the last meeting of the Asthma Research Council. The clinic holds that this depends largely on how the tests are carried out. In their opinion they should be only prick tests made vertically down to the cutis vera through the pathophane which is being tested, and this pathophane must usually be as strong as possible. Thus the minimum of surgical intervention is combined with the maximum of pathophane reaction. The false positive reactions which seem to be the bugbear of some asthma clinics are in this way avoided. To simplify the process of desensitization, which at present requires some forty injections, an attempt is being made to alter chemically the antigen so that the dose can be more rapidly increased without undue reactions. To this end an albumin protein complex has been obtained from timothy pollen which has a skin reactive potency of 1 in 5 million and yet retains its hay fever specificity.

At St Thomas's Hospital the value in asthma of respiratory exercises and short wave therapy to the nose and chest have been investigated. In the majority of cases chronic rhinorrhea rapidly cleared up under this treatment and there was a relapse in only a small percentage. The results were better from this combination than from respiratory exercises alone. The latter generally diminished both the intensity and the frequency of the attacks but did not affect any nasal infection present. Similarly, if the precipitating factor, such as an infected antrum, was alone treated by short wave therapy, without breathing exercises, the asthmatic mechanism of the chest remained and attacks were just as severe when some other precipitating factor appeared. The best results were obtained by the combination of exercises and short wave therapy to the antrums, and in the presence of severe bronchitis great relief followed short wave therapy to the chest. Attention to the general health was the only additional treatment. Cod liver oil was given to children under weight.

#### Air Raid Precautions

Air raid precautions continue to be the burning question of the day. This densely populated country, in which more than half the population is urban offers an abundance of targets for such attacks as are now witnessed in China. The Ministry

of health has set up a special department to prepare hospital accommodation, to advise on equipment and to control medical personnel. London is a special problem. It and the surrounding counties have been divided into three zones. In a crisis the inner zone hospitals will remove their ordinary patients to make room for mass surgical procedures, evacuating the wounded to the outer zone as soon as possible after operation. The outer zone hospitals will be placed in situations of reasonable safety and will act as base hospitals. Some of them will be set apart as special centers, neurologic, orthopedic and so on. First aid parties to the number of from twelve to fifteen per hundred thousand of population, each provided with an automobile, are being organized to collect casualties from the streets or other places. They will send the slightly injured home, those who require treatment as walking wounded to first aid posts and those who are stretcher cases by ambulance to the casualty clearing hospitals, which will normally be the local hospitals. On the threat of air attack these hospitals will be freed by evacuation to outlying hospitals of all patients who can be moved. Base hospitals will be in rural areas out of the danger zone and will retain casualties evacuated from the casualty clearing hospitals. It is anticipated that it may be necessary to use buildings other than existing hospitals for this purpose. The official estimate of casualties has never been published but various unofficial estimates have been made. For London they vary from 100,000 in twenty-four hours downward. On the outbreak of war the child population will at once be evacuated from London and the large industrial centers and be billeted in the houses in rural areas, of which a survey has already been made.

#### Assisting Academic Refugees

The Society for the Protection of Science and Learning of which the late Lord Rutherford was president, has rendered great service in finding posts for refugee scholars and researchers. The German persecution has made the continuance of its activities necessary. Meetings will soon be held in all academic centers to promote its work and protest against further threats to intellectual liberty and the freedom of academic life. At the same time the Royal Society will hold a reception for academic exiles in this country as a sign of its sympathy and approval of the work. During the five years of its existence the Society for the Protection of Science and Learning has received active support of university staffs in Great Britain. Individuals and committees have lent assistance to exiled colleagues. There is practically no college or university which is not harboring at least one refugee. Balliol College Oxford, has voted \$5,000 to be spent in assisting exiled scholars, and Christ Church has put aside \$900 a year for three years, in addition to what they were already doing. Glasgow University has made an appeal to its staff for a special levy and at Edinburgh Prof. Dover Wilson will give a special series of lectures on behalf of the assistance funds. Among those who will take part in the meetings are Sir William Bragg (president of the Royal Society), Sir Henry Dale FRS, Professor Gilbert Murray and Sir Richard Gregory.

#### Prof. Rutherford Morrison

The death of James Rutherford Morrison in his eighty-sixth year has removed a great surgeon and teacher. The son of a physician he was born in Durham on the fringe of a coal mining district. He studied medicine in Birmingham and Edinburgh, where he qualified in 1874. The early death of his father made it necessary for him to begin practice, which he did in Hartlepool where he became physician to the local hospital. After fifteen years of general practice he moved to Newcastle, where he was appointed assistant surgeon to the Royal Infirmary. His originality and great teaching power

soon made him famous and he was appointed professor of surgery at the university. As a surgeon he was twenty years ahead of his time. In the late eighties he was doing gastrectomies and colectomies and introduced the method of removing a growth from the lower part of the colon by producing intussusception with an anal tube. Foreign surgeons visited his clinic, remote though it was from London. Long before Crile described his method of clearing the neck, he was doing elaborate dissections for malignant disease of the lip and mouth. He introduced the operation of omentopexy for the radical cure of ascites. The Dutch surgeon Talma had also conceived the idea of producing this collateral circulation, but it was Morison who had the first success. In the great war he introduced what is known all over the world as "bipp" as a prophylaxis against and a cure for wound sepsis. This is a paste consisting of iodoform two parts, bismuth subnitrate one part and paraffin sufficient to make a paste. Its advantage was that a septic wound could, after cleansing, be filled with the paste and sutured without drainage and would heal under a single dressing. The Thomas splint, as the first aid measure for gunshot fractures of the femur, and "bipp" are important advances which have survived the great war.

Of his many publications he is best remembered for his "Introduction to Surgery," a remarkable book reflecting his genius as a teacher. His object was to aid students in thinking out for themselves the problems presented in the wards. His method was the consideration of general principles and their application. Though it appeared as long ago as 1910, it is still popular in its third edition, produced with the assistance of his pupil Prof. C. M. Saint.

### Clinical Aspects of Endometriosis

At the Dec. 14, 1938 meeting of the Académie de chirurgie de Paris, Drs. Gaston Cotte and J. Mathieu of Lyons reported their observation of seventy-eight cases of endometriosis confirmed by microscopic examination. There was a single localization in sixty-one cases and multiple localizations in the others. Single localization includes diffuse endometriosis of the uterus twenty-eight cases, of the tubes thirteen cases, of the ovaries eight cases and of the pelvic peritoneum seven cases.

The diagnosis of endometriosis presents many difficulties. When the endometriosis is only an associated condition no special treatment is indicated but there are cases in which the symptoms are functional and will not be relieved unless the endometriosis is eliminated. Certain symptoms should arouse suspicion, such as dysmenorrhea several years after puberty or in the premenopausal period. The pain occurs on the second or third day of menstruation and not before menstruation, as is customary in dysmenorrhea. A similar clinical history is observed only with certain uterine malformations when a circumscribed hematometra is present, just as it is with certain endometrioses. A dysmenorrhea of the type just described was noted in 75 per cent of the cases. Vaginal examination is of only indirect aid. The presence of pale blue nodules in the posterior cul-de-sac has been considered an important observation but such nodules are rarely found. The palpation of irregular nodules on the uterosacral ligaments also speaks for endometriosis but it must be remembered that in certain cases of parametritis similar nodules are found.

Even when a diagnosis of endometriosis has been made the question arises as to whether radical or conservative measures should be employed. The localization is of aid in making a decision. With peritoneal localization, if the lesion is small

and circumscribed it can be left because there is usually a more important associated condition, such as retroversion or uterine fibroid tumor, which needs attention. Tubal endometriosis may not give rise to any symptoms and be found only on microscopic study. In some cases such a localization may give rise to a hematosalpinx or favor an extra-uterine pregnancy. In only one of eight cases of ovarian endometriosis was this condition the cause of late dysmenorrhea. Such late dysmenorrhea was noted in four of sixteen cases of uterine localization and is of diagnostic value.

Endometriosis, although not to be considered as being of a malignant character, is a steadily progressive lesion whose evolution can be checked only by a natural or artificial menopause.

### OPERATIVE MEASURES

Cotte and Mathieu were opposed to any radical operative measures as advocated by some gynecologists. In over half of their cases, conservative operations sufficed. The administration of ovarian substance only aggravates the symptoms. One should be very sure of the diagnosis before beginning radiotherapy, as premature castration, when the diagnosis was wrong, would be very regrettable.

In cases of endometriosis with multiple localizations, bilateral oophorectomy is indicated. Hysterectomy should be done only if there is an associated lesion in the uterus. Rectovaginal adenomyomas are especially serious localizations of endometriosis. The authors have had very good results following subtotal hysterectomy with removal of both tubes and ovaries.

For the peritoneal forms as associated lesions it suffices to treat these lesions. If the treatment is not successful, more radical measures are indicated.

For localized adenomyoma of the uterus, resection can still be done, but if the lesion is diffuse only hysterectomy can be considered. With tubal endometriosis, the involved tube should be removed. In cases of bilateral involvement the uterus and one ovary should be conserved. With unilateral or bilateral ovarian endometriosis, every effort must be made to conserve an ovary.

### Subacute Bacillus Funduliformis Septicemia

Only twenty-seven cases of *Bacillus funduliformis* septicemia following acute pharyngitis and tonsillitis have been thus far reported. At the Oct. 28, 1938 meeting of the Société médicale des hôpitaux of Paris a case was reported by Dr. Brule and his co-workers of subacute septicemia due to this bacillus which had developed after severe pharyngitis. A man aged 34 was admitted to the hospital with marked prostration, rapid pulse and slight icterus, which appeared out of proportion to the condition of the throat. The bacteriologic examination failed to reveal the presence of diphtheria bacilli. During the next two days there were repeated chills, a high blood urea content and albuminuria. *Bacillus funduliformis* was found in the blood cultures on the first and following days. Death occurred four days after admission. Permission for a necropsy could not be obtained.

Lennerre, Reilly and Laporte in a recent article state that a high blood urea content, marked albuminuria and very marked leukocytosis are found in cases of *B. funduliformis* septicemia as evidence of renal involvement.

In the discussion of Dr. Brule's paper, Dr. Lenegre reported a case of severe *B. funduliformis* infection in a woman aged 23. The symptoms appeared several months after an attack of pharyngitis. The chief clinical features were recurrent high temperatures and severe diffuse pain, sometimes in the abdomen and sometimes in the extremities, with blood cultures positive for *B. funduliformis*. These symptoms receded rapidly after intravenous injection of a preparation containing iodine, naphthamine and sodium salicylate.

## The Society of Natural Scientists and Physicians

The annual congress of the Society of Natural Scientists and Physicians convened in September at a time of political high tension. This society is distinguished not only for its venerable age but for the opportunities it offers for collaboration between the natural sciences and medical science. Various societies of scientific specialists usually hold their respective congresses just before or just after the larger gathering.

The first general session was dedicated to the problem complex Climate and Life. Ludwig Weickmann of Leipzig delivered the introductory lecture. As first medical speaker Prof. Bernhard de Rudder of Frankfurt on the Main spoke on "Season and Weather in Human Biology." He stated that an initial, direct, clinically observable group of bioclimatic phenomena in man is to be found in the sharply fluctuating seasonal incidence of numerous types of disease. There is no general principle which makes these manifestations comprehensible; rather, each particular, empirically established observation requires separate interpretation. Many seasonal increases in the morbidity of a disease are found to be conditioned by recurrent seasonal external circumstances, which are however quite often not completely recognizable at first glance (for example, tularemia and measles). We have recognized the need for assembling all known factors in the genesis of an illness as well as the great danger that, in study of the seasons problem, omnipresent formal and anatomic correlations may be misinterpreted as etiologic. Nevertheless climatic factors directly affecting human beings are not infrequently first recognizable as such only after more penetrating analysis of their action. Such an influence is best illustrated by the high summer mortality of nurslings, which has been proved a direct result of warm weather. We are just beginning to recognize certain secretory reactions to the estival irradiation, which are especially manifest in an intensified degree in the female organism. Thence a bridge leads to an annual endocrine cycle, the initiation of which appears to take place chiefly through ultraviolet irradiation. Through these channels certain seasonal predispositions to illness appear to come into being.

A second group of meteorobiologic phenomena relate to the "weather pains" which synchronize above all with the appearance of weather fronts and which also relate to the accumulation of a large number of well circumscribed disease entities. The latter often originate in a completely nonspecific manner in that the weather fronts burden the sympathetic nervous system whereas the type of nervous reaction of the individual will depend on his particular physical condition at the particular time. The "biotropic weather front factor" active in such cases is not yet understood; it appears, however, to be related to the descent of air masses, which produce quick changes in water vapor. There seem to participate therein certain atmospheric properties, not yet understood, which in turn affect the human being.

## CLIMATE AND RHEUMATISM

Siegfried Dietrich of Berlin spoke on "The Hereditary Conditionality and the Climatic Conditionality of Rheumatic Disorders." The infection present with these disorders plays a subordinate part; more important are the hereditary constitution, the regular changes in the somatic constitution and the modifying influence of environment. Hereditary conditionality is manifested in rheumatic fever, which, as a familial accumulation, can often be observed through several generations and even under the most varying living conditions. Important familial tendencies to the diseases which precede rheumatic fever have been observed for example a high familial incidence of tonsillitis. However there exists in addition a linking with other constitutionally conditioned diseases (and allergies in particular), so the tendency to become infected with rheumatic fever may

conceivably depend on many hereditary factors. The incidence and form of manifestation of rheumatic fever change regularly according to the patient's age. The youthful groups are particularly imperiled. The tendency to rheumatic fever is observed in all races, although there are slight racial differences in the pathologic diathesis. The geographic distribution of rheumatic fever varies even among people of the same race inhabiting different quarters of the globe. Rheumatic fever is virtually unknown in tropical America, whereas beyond each tropic to the north and to the south the morbidity gradually increases. Even within Germany there are regional differences in the morbidity, which tend to remain constant for decades. Certain communities have also been found which are peculiarly suitable for the early climatic therapy of rheumatic fever. The salubrious advantages of such places may be confined to an extremely restricted zone, which may be surrounded by a region particularly unfavorable for rheumatic patients.

## THE WHITE RACE AND THE TROPICS

The closing paper, on "Adaptability of a Human Being to a Climate Inimical to His Particular Race," was read by the Heidelberg hygienist Prof. Ernest Rodenwaldt. Although the European as an individual may tolerate the tropical climate even under the most trying circumstances, it is doubtful whether he could adapt himself to the tropical climate for long uninterrupted periods or for a lifetime without any pathologic disturbances. Rodenwaldt adduced as a classic illustration of his view that in six millenniums of world history there is no single instance of a successful assimilation of light skinned European races by a hot climate. For Europeans the great danger of tropical diseases has by now been largely if not completely abolished. However, this by no means signifies that the influence of climate has at the same time become unimportant. Individuality here plays a considerable part. Persons whose sympathetic nervous systems are weak or who are allergic encounter greater difficulties than the average. Practical experience has demonstrated, however, that healthy Europeans of every constitutional type between the ages of 20 and 60 can live under the usual conditions offered by colonial life in the tropics without manifestation of constitutional disturbances. But without certain modifying conditions individual acclimatization is impossible; hence the necessity for intermittent furloughs home. Such furloughs may be dictated by psychic considerations as well.

## 'GIANT MOLECULES' "RACE AND CLIMATE"

The chief theme of discussion at the second general session was "Giant Molecules." Other problems taken up at this session were "Protein Synthesis in Physiologic and Pathologic Life" and "Myosin Substances."

Genetics was discussed in the principal medical section. The first speaker was Prof. Fritz Lenz of Berlin, on "Race and Climate." The decisive factor for extinction or survival occurs only in small part through direct climatic influences; climate is much more likely to act as an indirect influence wherein the cultivating effect of ecologic living conditions is of the utmost importance for the racial differentiation. On these bases Lenz develops a theory of ethnogenic selective factors. In his opinion parasites, and microparasites in particular, represent an ethnogenic factor of selection. For example, the selection of malaria, a disease which among inhabitants of tropical lands is usually a childhood disease of quite low mortality, suffices to keep tropical races resistant to malaria. Lenz maintains that the selective process appears to be related indirectly and directly to pigmentation. The more dark skinned the race, the greater its general resistance to malaria. Lenz has come to believe that the dark pigmentation of the colored races is in good part produced by malaria. According to this view the greater resistance of colored races against malaria should not be considered as immunity in the stricter sense but as hereditarily conditioned resistance. Lenz conjectures that, just as malaria may genetically conduce toward dark pigmentation of a race, tuberculosis

may conduce toward a light skin. In every part of Europe under the influence of the Gulf Stream the tubercle bacilli take the place, so to speak, of Plasmodidae as ubiquitous microparasites. Lenz estimates the number of permanent carriers of the tubercle bacillus as at least one third of mankind. Light exerts a recognized prophylactic and curative effect on tuberculosis. Consequently, since fair skin is more permeable to light than dark skin, the fair skin of European races has been preeminently cultivated through tuberculosis. This is not to say that races can be modified at will by climatic or environmental influences. Modifications of the breed through climate affect relatively superficial characters. The matrix of the sum of heritable factors of a race is not conditioned by climate.

His report and the few other congress reports on similar topics all attest the controvertible nature of these questions. Accordingly it is extremely important that problems of ethnogeny should be presented to learned bodies for discussion.

## BUCHAREST

(From Our Regular Correspondent)

Dec 15 1938

### Malaria Therapy in the Patient's Home

Dr Mihail Kraus, neurologist at Timisoara, read a paper at the local medical society on the application of malaria therapy in the patient's home. It was the general opinion that, owing to the unpredictable course of malaria therapy, it should be induced only in institutions where nurses and medical help are always available. Of course, patients with excessive fever and profuse sweating need careful nursing, but this can be assured just as well in a private home. In cases of mania institutional treatment is most suitable because in a home one cannot guarantee the cessation of an irritational condition and the possibility of the occurrence of hallucinations and epileptiform seizures must be reckoned with. When these complications can be expected, home treatment is not desirable. But in the simply demented and melancholic forms, in incipient dementia paralytica and in tabes malaria treatment in the home can be administered without any fear of untoward consequences. In the Vienna clinics not one case of fatal induced malaria has been recorded. What deaths occurred were due to terminal or galloping paralysis. It is advisable to exclude from home treatment very fat or emaciated or very old persons and those suffering from advanced arteriosclerosis, severe myocarditis, hepatic and renal disease, tuberculosis and decompensated heart disease. Satisfactorily compensated valvular diseases form no contraindication to home treatment but require careful control of the heart for the sake of avoiding collapse.

To shorten the incubation period in home treatment, malaria inoculations should be given intravenously and if there is an intelligent person in the house he should take the temperature hourly from the commencement of fever attacks and place compresses on the head and trunk when the fever is highest and at the outset of sweating should give some cardiac stimulant (atrophanthus digitalis or digalen). The attending physician should see the patient as often as his time allows, but at least twice a day. If the patient's strength is considerably deteriorating and disturbances of the pulse rate occur or if anemia and jaundice are marked it is time to stop the fever by the administration of quinine. In view of all this Kraus concluded that physicians may safely undertake to perform malaria therapy in private homes.

### Social Conditions of School Children in Rumania

Dr G. Banu made a clinical anthropologic and social-hygienic study on 2,149 school and nursery children, of whom 1,611 were urban and 538 rural dwellers and 1,107 were boys and 1,042 girls. In every case the nutritional condition, the relation between height, weight and age, the foods consumed the causes of undernourishment and the presence of tuberculosis and syphilis

were studied. The results of the clinical examination, the Pirquet reaction, the Wassermann reaction, radiography and analysis of the feces were recorded on a chart specially compiled by Dr. Banu. A third of the children had more than four living brothers or sisters. In 82 per cent of the cases the parents suffered from some chronic disease. 12.4 per cent of them were orphans, having no father, while 1.6 per cent of the children had neither father nor mother, 62 per cent of the children lived in unhygienic dwellings, only 8.7 per cent had their own rooms, 21 per cent of the children had their own bed and 46.6 per cent shared their bed with another and 17.7 per cent with two others.

### Program of the Supreme Public Health Council

Under the presidency of M. Marinescu, minister of public health, a meeting was held recently and it was decided to carry out in the near future the following program: 1. Regulations will be elaborated according to which the members of the Orthodox Rumanian Monks shall be trained to be able hospital nurses. 2. Plans will be made for the installation of a huge storehouse for public health materials and drugs. 3. New regulations will be compiled for teaching the technique of embalming and also the preparation of the solutions used. 4. In the matter of contraceptives, it was resolved to forbid their use and all propaganda in connection with them. On the other hand all drugs and appliances which serve the purposes of antivenereal propaganda are permitted, and their sale in chemists and druggists shops is allowed. 5. As to the campaign against scarlatina, it was resolved that, until a reliable method of vaccination is adopted, compulsory vaccination will be introduced only in some heavily infected cities and that antiscarlatinal vaccines which have been proved harmless after thorough investigations will be used.

### The Review of Foreign Diplomas

As I wrote in a previous letter, all foreign diplomas issued since the World War have been subjected to review. The commission had to review about 3,500 diplomas, which entailed much work. It found that, with the exception of a few diplomas issued at some obscure foreign universities, all were in order. In about a score of instances, and particularly in the case of Italian diplomas it was found necessary for holders to pass supplementary examinations on one or two subjects, such as public hygiene, pharmacology and forensic medicine.

## Marriages

CHAUNCEY JOHNSON PATTEE, Montreal, Que. Canada, to Miss Barbara Russell Stearns of New Canaan, Conn., Sept. 10, 1938.

RAYMOND LESTER OSBORNE, Orangeburg, N. Y., to Miss Margaret Forbes Unangst of Westwood, N. J., January 22.

EDWARD WILLIAM PHIFER JR., Morganton, N. C., to Miss Mary Adair Edwards of Orlando, Fla., Nov. 5, 1938.

WILLIAM A. MAYNARD, Coleman, Mich., to Miss Mildred Bruskotter of Saginaw, in December 1938.

JOHN H. KENDALL, Richlands, N. C., to Miss Bessie Mae Hood in Washington D. C. at Takoma Park Md. Nov. 3, 1938.

LADISLAUS JOHN KUNSCH, Naperville, Ill., to Miss June McNeeney of West Chicago, Oct. 1, 1938.

HOVER S. PARKER, McMechen, W. Va., to Miss Cora G. Sullivan of Moundsville, Sept. 4, 1938.

LUCIUS BRAYNER KFELS, Lynchburg, S. C., to Miss Evelyn Plowden of New Zion at Sumter, Nov. 26, 1938.

MILTON MORTIMER KENDALL, New York, to Miss Ann Philo of Youngstown, Ohio, Nov. 24, 1938.

ARTHUR J. MERRILL, Atlanta, Ga., to Miss Sara Harrison of Birmingham, Ala., Nov. 25, 1938.

THOMAS M. MULLCAHY, to Miss Ethel Mildred Harlow, both of New York, Nov. 12, 1938.

LOUIS H. MITSCHLIK, to Miss Isabelle Carleton Graves, both of Philadelphia, January 4.

## Deaths

**William Thomas Black** \* Memphis, Tenn., Memphis Hospital Medical College, 1898, professor of gynecology at the University of Tennessee College of Medicine, member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Southern Surgical Association, Central Association of Obstetricians and Gynecologists and the Southeastern Surgical Congress, fellow of the American College of Surgeons, on the staffs of the Baptist Memorial, St. Joseph and Memphis General hospitals, past president of the Memphis and Shelby County Medical Society and of the Memphis Obstetrical and Gynecological Society, on the advisory editorial board of the *American Journal of Obstetrics & Gynecology* aged 63, died, Dec 10, 1938

**Henry du Rest Phelan** \* Major, U. S. Army, retired, Alameda, Calif., University of California Medical Department, San Francisco, 1893, Université de Paris Faculté de médecine, France, 1903, veteran of the Spanish-American and World wars, entered the medical corps of the regular army as a first lieutenant March 15, 1927, and was retired on the same date for disability in line of duty in June 1930 was promoted to major under a special act of Congress, aged 70, died, Nov 22, 1938, in the Letterman General Hospital, San Francisco

**William J. V. Deacon**, Lansing, Mich., Eclectic Medical University, Kansas City, Mo., 1917, director, bureau of records and statistics, Michigan Department of Health, and formerly epidemiologist, associate professor of preventive medicine at the University of Kansas, 1913-1918, lecturer on vital statistics, University of Michigan, Ann Arbor 1921-1933, and the Wayne University, Detroit since 1927, in 1929 a member of the U. S. Delegation to the International Conference for Revision of List of Causes of Death, Paris, aged 64, died, Dec 20, 1938, at his home in East Lansing, of heart disease

**John H. Murray**, Punxsutawney, Pa., Medico-Chirurgical College of Philadelphia, 1895, member of the Medical Society of the State of Pennsylvania, member of the House of Delegates of the American Medical Association in 1924 and 1927, past president of the Jefferson County Medical Society, aged 71, on the staff of Adrian Hospital, where he died, Nov 16, 1938, of bilateral nephrosis with uremia

**Elizabeth Catherine O'Hearn**, Shenandoah, Pa., Woman's Medical College of Pennsylvania, Philadelphia, 1927 member of the Medical Society of the State of Pennsylvania on the staff of the Locust Mountain State Hospital, aged 36 died Nov 11, 1938 in the University Hospital Philadelphia, of septicemia following sticking of her finger, November 2 while incising a carbuncle

**Thomas Ulysses McManus**, Waterloo, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898, member and past president of the Iowa State Medical Society, fellow of the American College of Surgeons, Otolaryngologist to the Allen Memorial Hospital and St. Francis Hospital, aged 65, died, Nov 5, 1938, of pneumonia

**Daniel Franklin Heilman** \* Northumberland, Pa., Medico-Chirurgical College of Philadelphia, 1899, past president of the Northumberland County Medical Society, past president of the board of health, formerly bank president and medical examiner of the public schools, on the staff of the Mary M. Packer Hospital, Sunbury, aged 62, died, Nov 28, of embolism

**Aloysius John Blakely**, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1927, was an associate in pediatrics at his alma mater, on the staffs of St. Luke's Children's, St. Joseph's and St. Mary's hospitals, aged 40, senior in the department of pediatrics at the Hahnemann Hospital, where he died Nov 27, 1938, of heart disease

**Heman Lincoln Chase**, Alstead, N. H., Harvard University Medical School, Boston, 1887, member of the Massachusetts Medical Society, formerly member of the board of health of Brookline, Mass., for many years on the staffs of hospitals in Boston, Worcester and Danvers, Mass., aged 79, died Nov 17, 1938, of cerebral thrombosis

**Joseph Oscar Dicks**, West Chester, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1899, member of the Medical Society of the State of Pennsylvania, fellow of the American College of Surgeons, on the staff of the Chester County Hospital, aged 63, died, Nov 14, 1938, of coronary thrombosis

**John Henry Page** \* Austin, Pa., University of Buffalo School of Medicine 1902 fellow of the American College of Surgeons, past president of the Potter County Medical Society, attending surgeon to the Coudersport (Pa.) Hospital, aged 61, died Nov 26, 1938, of coronary heart disease

**Jesse Samuel Lancaster** \* Torrance, Calif., Northwestern University Medical School, Chicago, 1910, on the staff of the Jared Sidney Torrance Memorial Hospital, aged 55, died, Nov 5, 1938, in a hospital at Los Angeles

**Walter C. Rosser**, Lynchburg, Va., University College of Medicine, Richmond, 1896, member of the Medical Society of Virginia, aged 63, died, Nov 24, 1938, in the Memorial Hospital, of malignancy and tuberculosis

**Willoughby Heath Tebbs Ranshaw**, Covington, Ky., Miami Medical College, Cincinnati, 1907 served during the World War, aged 54, died, Nov 28, 1938, in St. Elizabeth Hospital of mitral regurgitation

**John H. Owens**, Sweet Springs, Mo., Hospital College of Medicine, Louisville, Ky., 1897 member of the Missouri State Medical Association, aged 80, died, Nov 10, 1938, of coronary thrombosis and myocarditis

**Robert Alvin McLurg**, Wilkie, Sask., Canada, Trinity Medical College Toronto, Ont., 1904, member of the school board, past president of the Saskatchewan Medical Association, aged 60, died, Nov 5, 1938

**Martin Luther Wagner**, Peru, Ind., Indiana Medical College School of Medicine of Purdue University, Indianapolis, 1907, served during the World War, aged 61, died, Nov 30, 1938, of heart disease

**David H. Carson**, Kerrville, Texas, John A. Creighton Medical College, Omaha, 1905, member of the State Medical Association of Texas, aged 61, was found dead with a gunshot wound, Nov 2, 1938

**Frederick Henri Gatten**, Montreal, Que., Canada, Laval University Medical Faculty, Montreal 1907, formerly on the staff of the Hospital St. Joseph, Lochme, Que., aged 55, died, Nov 14, 1938

**Jay Standley Terrill**, Bedford, Iowa, Ensworth Medical College, St. Joseph, Mo., 1906 member of the Iowa State Medical Society, aged 56, died, Nov 17, 1938, of rheumatic heart disease

**George Edward Clerk**, Montreal, Que., Canada, Laval University Medical Faculty, Montreal, 1911, served with the Canadian Army during the World War, aged 61, died, Nov 15, 1938

**Joseph Alonzo Peterson**, Oak Park, Ill., Chicago College of Medicine and Surgery, 1908 aged 63, died, Nov 4, 1938 in a hospital at Chicago of cerebral hemorrhage and acute nephritis

**William H. Allen**, Rich Hill, Mo., Louisville (Ky.) Medical College, 1871, member of the Missouri State Medical Association, formerly mayor, aged 90, died, Nov 8, 1938, of heart disease

**Andrew Bell Wilkie**, Darrrtown, Ohio, Cincinnati College of Medicine and Surgery 1902 served during the World War, aged 75, died, Nov 6, 1938, of chronic nephritis and fractured hip

**Lucien Daniel Clark**, Cleveland Heights, Ohio, Toledo Medical College 1898 served during the World War, aged 72 died, Dec 3, 1938, of bulbar paralysis and cerebral hemorrhage

**Sarah A. Poindexter Bent**, Narberth, Pa., Woman's Medical College of Pennsylvania Philadelphia, 1893, medical missionary, aged 70, died, Nov 27, 1938, near Norristown

**John Joseph Winn** \* Norwood, Ohio, Medical College of Ohio, Cincinnati, 1885 aged 80, died Nov 4, 1938, in the Good Samaritan Hospital, Cincinnati, of coronary thrombosis

**Otto G. Waskow**, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, aged 62, died, Nov 16, 1938

**John H. Neill**, Westfield, N. Y., University of Maryland School of Medicine, Baltimore, 1889 aged 82, died, Nov 13, 1938, of cardiorenal vascular sclerosis

**Ray G. Hill**, Wamego, Kan., Hahnemann Medical College and Hospital, Chicago, 1889, member of the Kansas Medical Society aged 79, died Nov 25, 1938

**George Brown Mills**, Athabaska, Alta., Canada, Trinity Medical College Toronto, Ont., 1896, aged 70, died Nov 17, 1938

**Charles Wesley Shannon**, Bonne Terre, Mo., Missouri Medical College, St. Louis, 1895, aged 81, died, Nov 4, 1938

**Ulysses G. Lipes**, Indianapolis, Fort Wayne (Ind.) College of Medicine 1885 aged 74 died Nov 21, 1938 in Lafayette

**Max Heller**, Brooklyn, Fordham University School of Medicine New York 1919, aged 54 died, Oct 28, 1938

**John B. Washburn**, Delmar, N. Y., Albany Medical College 1882, aged 81 died Nov 27, 1938, of pneumonia

## Bureau of Investigation

### THE GEORGE A EDAM FRAUDS

#### The Sabo Painless Hair Remover Fake

From two memorandums addressed to the Postmaster General from the office of the Solicitor of the Post Office Department and, in part, from material on file in the Bureau of Investigation of the American Medical Association comes the story that follows of a mail order quack, one George A. Edam of Cleveland.

In 1925 Edam began selling through the mails a device called 'Sabo Painless Hair Remover'. It was a small cylinder about 3 inches long with a metal plunger at one end and metal jaws at the other end. When the plunger was depressed the jaws were extended to grasp an unwanted hair. A trigger at the plunger end released a spring tension that caused the jaws to close and automatically jerk back into the cylinder, pulling from the skin the hair caught in the jaws. In other words the Sabo Painless Hair Remover was merely a convenient method of using tweezers and if sold under truthful claims might have been comparatively unobjectionable.

Edam, who was a wood and metal pattern maker, originated his device with the idea of extracting hairs from portions of the body where they were unwanted and then attempting to deposit such hairs in the scalps of bald-headed persons! But as the experiment in cranial hirsuticulture proved a failure Mr. Edam confined his talents to selling his device for removing hair. He obtained his victims in the orthodox way, by the

"placing of advertisements in certain periodicals and magazines." One of Edam's advertisements is reproduced on this page, it appeared in Macfadden's *Physical Culture* for July 1929.

Edam sold his device under two claims that were false. First, he claimed that it would remove hair "painlessly"; second, that it would remove hair "permanently." It did neither. As long ago as May 1934 the Federal Trade Commission announced that George A. Edam, trading as the Edam Manufacturing Company, had agreed to cease describing his device as one that would permanently remove hair. But Mr. Edam's agreement evidently was made in a pickwickian sense, for he continued for some years to advertise that his tweezers would remove hair permanently.

Three years after the Federal Trade Commission had announced Mr. Edam's promise to tell the truth the Post Office Department in July 1937 notified the Edam Manufacturing Company to show cause why a fraud order should not be issued against it. But Mr. Edam by this time apparently thought that the federal government was an innocuous affair, for neither he nor his company put in any appearance. The Post Office Department through its Acting Solicitor thereupon sent to the Postmaster General a memorandum recommending that a fraud order be issued against the Edam Manufacturing Company, the mails were closed to the concern Aug. 17, 1937.

Did that faze Mr. Edam? It did not! True the Edam Manufacturing Company could collect no mail but all Mr. Edam had to do—and did do—was to pluck out of the vasty deep another trade name and continue to bilk the sufferers from hypertrichosis. The new trade name was Sabo Manufacturing Company, which carried on the business for about a year. Then following still another memorandum from the Solicitor's office the Postmaster General on Aug. 26, 1938 issued another fraud order closing the mails to the Sabo Manufacturing Company.

Whether Mr. Edam will think up another trade name under which to do business remains to be seen.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

### BRONCHIAL ASTHMA AND HEART FAILURE

*To the Editor*—It is understood that right heart failure is often the cause of death in chronic bronchial asthma. Would digitalis therefore be indicated to pep up the failing muscle?

HERMAN WECHSLER, M.D., Bronx, N.Y.

**ANSWER**—The query is based on a premise which is highly controversial. Several clinical conditions may be followed by failure of the right side of the heart and "asthma" may be but a part of the syndrome, though decidedly not a cause of the circulatory dysfunction. For example, miners' asthma commonly follows such a sequence. Antemortem as well as postmortem examinations may help to clarify the situation. Electrocardiographic studies of fifty cases of bronchial asthma revealed evidence of right ventricular preponderance in but 20 per cent of the series (Kahn, M. H. *Am J M Sc* 173:555 [April] 1927). In another series (Colton, W. A., and Ziskin, Thomas M. *Bull Vet Admin* 13:117 [Oct.] 1936) of eighty-four cases the heart was normal on clinical examination in seventy-nine. Electrocardiographic studies on fifty-six of the eighty-four subjects disclosed myocardial involvement in 20 per cent. In several of these the circulatory dysfunction antedated or was unrelated to bronchial asthma. Six of the total series were examined post mortem, four presented a normal heart, one may have had the cardiac abnormality before or coincident with the symptoms of asthma, and the sixth patient was said to have a slight degree of chronic exudative inflammation of the myocardium. Both left and right ventricular hypertrophy have been reported in a majority of eight cases (Macdonald, I. G. *Ann Int Med* 6:253 [Aug.] 1932).

On the opposite side of the controversy, one finds laboratory as well as clinical evidence (Alexander, H. L., Luten, Drew, and Kountz, W. B. *The Effects on the Heart of Long-Standing Bronchial Asthma* *THE JOURNAL*, March 19, 1927, p. 882) that the heart remains singularly free from injury after continuous bronchial asthma despite the attendant emphysema. This contention is supported by more than 100 necropsies (Lamson, R. W., and Butt, E. M. *Fatal "Asthma"* *THE JOURNAL*, May 29, 1937, p. 1843; Thume, E. T., and Sheldon, J. M. *J Allergy* 9:246 [March] 1938). It appears, therefore, that in no more than from 20 to 33 per cent of patients with asthma can the right side of the heart be implicated. This condition might be the cause of death in a small proportion of such a group.

There are a few generally accepted indications for the use of digitalis, but they do not include "right heart failure." The drug is not without toxic properties and in addition it may add to the discomfort and disability of the patient with asthma. The value of digitalis as a prophylactic against cardiac insufficiency or to "pep up" the failing heart muscle in any patient is likewise a moot question.

### DISCHARGE FROM UMBILICUS

*To the Editor*—What can be done for an offensive discharge from the umbilicus during menstruation? I have two patients, single women, one 17 and the other 23. I have tried to pass a probe but there appeared actually to be no duct in the umbilicus.

HOWARD M. COOPER, M.D., Rutherford, N.J.

**ANSWER**—Nearly always an offensive discharge from the umbilicus is due to lack of thorough cleanliness. In many women, especially obese ones, the umbilicus is deep and unless the tip of a wash cloth or a cotton applicator is used to reach the bottom of the navel, secretions from the skin remain and give rise to a foul odor.

Since in the cases described the discharge is not bloody, the condition is not due to endometriosis. Likewise since the discharge does not contain urine there is no patent urachus from the bladder to the umbilicus. The association with menstruation may be due to the increase in perspiration which some women experience during the menses. It may also be due to the fact that the patients do not bathe at this time, because many women still fear to take cleansing baths while they menstruate. The umbilicus should be thoroughly scrubbed with soap and water just as any other part of the body, but in women who perspire freely it requires special manipulation to keep clean and inoffensive.

## ANGIO-NEUROTIC EDEMA WITH LINGUAL AND OPTIC INVOLVEMENT

To the Editor—A single woman aged 40 without past medical history of importance has for two years suffered attacks of swelling and numbness of the left cheek and swelling and numbness of the tongue. The tongue in an hour or so appears covered by blisters which disappear however and the next day the tongue is coated swollen shaggy and numb on the affected side. The last attack one week ago was accompanied by sudden blindness in the right eye. No other symptoms accompany the attacks: the swelling and numbness of the cheek and tongue last two or three days and then disappear. Physical examination is negative. Laboratory examination of the urine and blood are negative. The fundus of the eye is normal. The visual tests reveal a blind spot which persists ten days after attack. Any suggestions would be appreciated.

RICHARD H. LYON, M.D. Seattle

ANSWER—The patient in all probability has an acute circumscribed edema, also known as angioneurotic edema. This condition was described as early as 1778 by Salpertus, in 1801 by Crichton, in 1848 by Graves, in 1872 by Milton and in 1882 and 1904 by Quincke. It is also known as Quincke's edema. The patient also has the type known as lingual bullosis, in which the tongue becomes covered with multiple vesicles. The blindness is due to a swelling of the optic nerve head. The most important characteristic of this entity is its tendency to appear without reason and after a few hours or days disappear only to return again at some later time. The edema may involve any part of the body, but usually the skin, the subcutaneous tissue and occasionally the mucous membranes are most often affected. The prognosis is extremely dangerous in cases of edema of the lottis because the patient may become asphyxiated unless intubation or tracheotomy is done at once. There is no special treatment. Overeating, worrying and restlessness should be corrected. Tenseness, panic and emotional states should be prevented if possible. Various foods should be eliminated from the diet if such foods are found to produce an attack (allergic). Epinephrine, ephedrine or amphetamine sulfate should be given for the acute attack if possible. Application of ice to the swelling if it is in the eyelid, cheek lip or parotid gland will be found to be helpful in reducing the size of the swelling as well as its duration. It is suggested that a textbook on neurology be consulted for further description.

## RECURRENT BOILS FROM ARSENIC COMPOUND

To the Editor—A mosquito control crew has been using the following modification of a weed killing compound manufactured by the Chipman Chemical Company of Bound Brook, N. J.

Active ingredients	
Dicalcium arsenite not less than	83.33%
Consisting of	
Arsenous oxide not less than	50.00%
Total arsenic (as metallic) not less than	37.87%
Water soluble arsenous oxide not more than	4.00%
Water soluble arsenic (as metallic) not more than	3.03%
Inert ingredients not more than	16.67%

To this standard compound has been added 10 per cent by weight of sodium arsenite. The mixture is dissolved in water and sprayed on the hydrants. The proportion used is approximately 4 pounds of the mixture to 50 gallons of water. After about a week's exposure to the solution the operators became affected with boils mainly on their arms and chests. After about a week's rest the condition of the men improved noticeably. It appears therefore that working with this compound may have some effect on the men which will result in a recurrence of the boils. Please advise whether the continued use of this compound would be detrimental in any way to the health of the men exposed to it.

T. R. GRIFFIN, M.D. St. Petersburg, Fla.

ANSWER—The condition described leads to the presumption that arsenic is the source of the disorder, although neither the nature nor the distribution of the dermatitis is characteristic. However, Rayer (A Treatise on the Theory and Practice of Skin Diseases, Paris, 1826-1827) as early as 1826 described pustulous skin disorders produced by arsenic compounds. In time, the terms "arsenic pock" or "arsenic pox" came into wide use. Usually a dermatitis, following exposure to arsenic-bearing dusts or sprays, is present about the eyelids, base of the nose, neck, armpits, elbows, hands and groins rather than on the chest. Also the lesion customarily is essentially papilliform, followed by ulceration, commonly associated with deep pigmentation and at times followed by keratosis or even neoplastic growth. As to arsenical furunculosis, White (Occupational Affections of the Skin, London, H. K. Lewis & Co., Ltd., 1934) states "Infection rapidly changes papules and vesicles into pustules, which readily burst and the contents reinfect the skin. Pimples and boils then become the prevailing type. Moisture, friction and continued irritation of the arsenic lead to ulcers." Continued exposure is not warranted in the absence of protective measures unless arsenic can be ruled out as the offending agent. These afflicted workers should be examined for other evidences of arsenic poisoning such as disturbances of the digestive, renal and circulatory systems.

## HAY FEVER AND VITAMINS

To the Editor—In the July 10, 1932 issue of *Industrial and Engineering Chemistry* (New Edition) appeared an article by K. Katsuta of the Ohio Agricultural Experiment Station Wooster, Ohio entitled "Hay Fever as a Symptom of Vitamin Deficiency." This article outlined a cure for hay fever consisting of the daily ingestion of four teaspoonful three times daily of cod liver oil plus a cake of yeast. Do you know anything of the present status of this treatment and whether or not further work has been done on it?

CARL P. SHERWIN, M.D. New York

ANSWER—Since vitamin therapy has been tried in almost every disease it is but natural that it should be attempted in hay fever. Crandall and Feinberg (*J. Allergy* 5:515 [July] 1934) gave daily doses of thirty drops of viosterol 250 D to a series of hay fever patients without any noticeable effect. Rappaport, Reed, Hathaway and Struck (*ibid.* 5:541 [Sept.] 1934) reported favorable results from the use of enormous doses of vitamin D in the form of irradiated ergosterol. Apparently these large doses were helpful in conjunction with the regular desensitization therapy. Their experience together with the experiences of others seems to indicate that doses of vitamin D of that magnitude may produce toxic and perhaps even dangerous symptoms. The use of cod liver oil in the doses mentioned by the inquirer has been employed by many physicians without any notable results. In unpublished work carried on at the Allergy Department of Northwestern University Medical School the following vitamin products in ordinary doses have produced no beneficial results in hay fever: vitamin A (carotene and fish oils), vitamin B (brewers' yeast), vitamin C (ascorbic acid), vitamin D (viosterol and fish oils).

## UNUSUAL MIGRAINE

To the Editor—A woman aged 35 has been having what has been diagnosed as attacks of migraine ever since 1932. Before an attack she has a depressed feeling which is soon followed by an excruciating headache. The location of the pain varies from time to time. Sometimes it begins on the right side of the head and goes to the left; again it starts on the left and extends to other parts of the head. During the attack she feels nauseated and vomits occasionally. Without efforts at relief this headache has lasted as long as four or five days, gradually wearing off. Furthermore during the attack light aggravates it. In 1930 the patient had a tonsillectomy after which it was necessary to stop the hemorrhage by suturing. In 1932 she had an appendectomy; the ovaries have not been touched. About two weeks after this operation the first attack of headache began. She did not have another until three years later, then the headaches began to precede each menstrual period. After a few months the headaches began to follow menstruation. During the past year the attacks have appeared twice weekly. A neurologist performed a spinal fluid test as well as a complete neurologic examination and found everything negative. He gave her five typhoid injections without effect. His diagnosis was migraine. An internist then had her skull as well as her gastrointestinal tract roentgenographed with negative results except for the finding of a curved surgical needle at the right angle of the left jaw. He treated her for six months by means of estrogen without any benefit. The patient was finally placed in a hospital for observation and treatment where she remained for six weeks. After a thorough examination nothing organic was found except the needle. She was advised to have the needle removed although she is not conscious of its presence. Ergotamine tartrate (gynergen) gave her relief at first but its efficacy soon wore off. Now she obtains some measure of relief from neoglynergen. Its effect however is also showing signs of diminishing.

M.D. New York

ANSWER—The patient described as having attacks of migraine presents the following unusual points: "onset" after an appendectomy, the presence of a surgical needle at the angle of the left jaw, and gradual diminution of the therapeutic efficacy of gynergen and more recently neoglynergen. If, as stated, the ovaries were not damaged during the operation, the subsequent appearance of the attacks of migraine is most likely coincidental. The needle likewise is probably not productive of the attacks. It should, however, be removed because it may be a source of irritation to the adjacent sympathetic chain.

It is presumed that gynergen is progressively less effective in stopping each succeeding attack and that neoglynergen is likewise less effective in aborting or terminating attacks. Neither is of value in preventing the recurrence of migraine headaches. It is unusual for either to lose their value. If either did so, it would be expected that neoglynergen would fail first because as a rule it is about half as effective as gynergen. Apparently no other instances of developed tolerance to ergotamine have been noted. These facts cause one to suspect (1) an approaching menopause, (2) an increase in the psychogenic aspect of the problem or (3) a progressive organic lesion, such as cerebral aneurysm or neoplasm.

The migraine syndrome is often the summation of abnormalities in the endocrine, psychic, allergic and other fields, resulting in intracranial vasomotor fluctuations. Each field should be thoroughly investigated and any abnormalities corrected. Small doses of emmenin three times a day have been found effective in diminishing the frequency of attacks in similar case.

inherent or acquired deficiency, which allows this patient to become a victim of neuritis, unlike the vast majority of patients who have acute or chronic appendicitis. Treatment by vitamins however, with our present state of knowledge, is to be recommended.

# RESPIRATORY FAILURE IN NEWBORN

To the Editor—A normal full term fetus delivered by an elective cesarean section exhibited complete respiratory failure and died. Autopsy by a competent pathologist revealed grossly only atelectasis of the lungs which was judged to be secondary in nature. A study of the cerebral cortex for evidence of cellular alteration by anoxemia is to be attempted. Twelve hours and eighteen minutes before anesthesia was begun the mother received one dose of sodium amytal 3 grains (0.2 Gm). Two hours and three minutes before anesthesia was begun morphine sulfate one sixth grain (0.01 Gm) with atropine sulfate 1/100 grain (0.0004 Gm) was administered. Nitrous oxide oxygen ether anesthesia was given by a competent physician anesthetist. Twenty three minutes elapsed from the beginning of the anesthesia to the beginning of the operation. Twenty seven minutes from the beginning of the anesthesia to the delivery of the fetus. A second cesarean section by the same operating group and the same anesthetist under similar medication with morphine and the same anesthesia resulted in a cyanosed infant which was resuscitated but developed inhalation (aspiration) pneumonia. The same operating group with other anesthetists but with the same medication and the same anesthetics has over the past two years experienced no fetal complications. Discussion appears directed chiefly to the preoperative medication to the anesthetic itself and to the amount of oxygen necessary to prevent anoxemia.

M D New York

ANSWER—The failure of the respiratory function in the newborn following delivery by cesarean section may be due to several factors. In the first place, narcosis may diminish the sensitivity of the respiratory center or cause a complete cessation of respiratory movements so that this function is not resumed at birth. The various analgesic and anesthetic drugs produce varied degrees of narcosis, depending on the character of the drug and the amount of it used. The barbiturates are more likely to produce a prolonged narcosis in the newborn than are the opiates. The second factor in asphyxia is the anoxemia produced by inhalation anesthetics. Here again the degree of anoxemia would depend on the anesthetic agent used. Snyder and Rosenfeld have shown experimentally in animals that the fetus requires at least 15 per cent oxygen in order that the respiratory movements are not interfered with. Less than 10 per cent oxygen produces an immediate suppression of fetal respiration, which may or may not be permanent, depending on the duration of the anoxemia. Thus, nitrous oxide must be administered with at least 15 per cent oxygen in order to avoid fetal anoxemia. This mixture in itself without the addition of ether will not produce anesthesia in the mother.

When a combination of narcosis and anoxemia exists, the danger of respiratory failure at birth is definitely increased. The exact valuation of the roles of the preoperative medication and the anesthesia in the production of fatal asphyxia of the newborn cannot be ascertained in each instance. Prompt and effective methods of resuscitation will reduce the incidence of serious or fatal asphyxia.

# PERIRECTAL SINUS AND EMPLOYABILITY

To the Editor—Precedents are desired with regard to the employability of a person having a perirectal sinus presumably of tuberculous origin. The discharge is slight. There are no other open tuberculous lesions. The patient's state of health is stabilized and he is considered physically able to carry on his former work. Are esthetic and hygienic considerations so serious that his former employer should consider him unfit to work with other employees and to use the same lavatories? He belongs to the white collar class.

M D New Jersey

ANSWER—No precedents have been found to interfere with the employability of a person having a perirectal sinus due to tuberculosis, without other demonstrable lesions.

# BIBLES IN BRAILLE

To the Editor—I have been asked to get a braille Bible for a blind patient but so far have not been able to locate a supply house that handles the book or knows where to get them. Could you tell me where I could acquire one?

JOHN T FRANCE M D Findlay Ill

ANSWER—Bibles in braille are available at the American Printing House for the Blind 1839 Frankfort Avenue Louisville Ky.

#### NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL February 11 page 573

### Rhode Island October Examination

Mr Robert D Wholey, chief, Division of Examiners, reports the oral, written, and practical examination held by the Board of Examiners in Medicine at Providence, Oct 6-7 1938. The examination covered 20 subjects and included 50 questions. An average of 80 per cent was required to pass. Six candidates were examined, five of whom passed and one failed. Four physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine	(1931)	86	
Harvard University Medical School	(1936)	86	
Jefferson Medical College of Philadelphia	(1936)	86

## Book Notices

**Diseases of the Chest and the Principles of Physical Diagnosis** By George W. Norris A.B. M.D. and H. R. M. Landis A.M. M.D. Sc.D. Diseases of the Bronchi, Lungs, Pleura and Diaphragm. Revised by Simon S. Leopold M.D. Assistant Professor of Medicine and Head of the Department of Physical Diagnosis in the University of Pennsylvania. Philadelphia. Transmission of Sounds Through the Chest. By Charles M. Montgomery M.D. Electrocardiography and the Cardiac Arrhythmias the X-Ray Study of the Heart and Great Vessels and Additional Methods of Cardiac Examination. By Thomas M. McMillan M.D. Physician to the Pennsylvania Hospital Philadelphia. Sixth edition. Cloth. Price \$10. Pp. 1019 with 478 illustrations. Philadelphia & London W. B. Saunders Company 1938.

This edition shows in every detail the march of progress in diseases of the chest over the last two decades. There is much in the first edition that is present today. It must be gratifying to the authors that what was the text of the diseases of the chest for clinicians, private physicians and students alike twenty years ago is still the text today. The edition as compared with the edition of 1917 is larger by more than 200 pages and is still divided into four sections: examination of the lungs, examination of the circulatory system, diseases of the bronchi, lungs, pleura and diaphragm, and diseases of the heart. The authors have been adept in separating the chaff from the wheat, in surveying the great amount of literature and research that has appeared in the world's medical periodicals each year. Through six editions in twenty-one years they have kept step with the times. We would like to refer the reader to the preface of the first edition in order that students may see what the authors hoped to do, what they most assuredly accomplished, as Millet's 'Gleaners' in the field of fact that concerned them, the diagnosis of the diseases of the chest in the last two decades.

It was, indeed, unfortunate that Dr. Landis died during the early work of this edition. By his request, however, during a long illness his task was taken over by an able clinician, Dr. Simon S. Leopold, who as a tribute to the memory of Dr. Landis, took over the latter's role in the revision of the previous edition and rewrote the chapters dealing with bronchial asthma, bronchiectasis, lung abscess, cystic disease of the lung and the relation of the nasal and accessory sinus disease to infections of the lower respiratory tract. The chapter on electrocardiography and the cardiac arrhythmias has been rewritten by Dr. Thomas McMillan, who has also added the chapter on the X-ray study of the heart and great vessels, a study profusely illustrated by diagrams.

With the recent progress of thoracic surgery, more refinement in the diagnosis of pathologic conditions of the chest has become necessary. This necessity has been fully realized by the added procedures of diagnosis, namely diagnostic pneumothorax, bronchoscopy, bronchography, thoracoscopy, roentgenograms, oblique and lateral views of lesions that may be hidden by the heart shadow, mediastinum, spine and domes of the diaphragm. The edition is completely illustrated with reduced prints of the roentgenograms, with postmortem roentgenograms of injected lungs, bronchographic diagrammatic sketches, photographs, charts, tables, colored plates of disease conditions of the chest, photographs of pathologic cross sections, sagittal and cross sections of the torso, and electrocardiograms, thus catering to the visual memory of the students of diseases of the chest.

**Cancer Diagnosis and Treatment. A Handbook for Physicians.** Compiled and edited by the Committee on Cancer Education of the Colorado State Medical Society. Paper. Pp. 75. Denver. Colorado State Board of Health 1938.

This is a handbook in brief and condensed form offered to the physicians of Colorado by the medical society and the board of health of that state as a part of the educational campaign against cancer, a campaign which includes education of the physician in the technical aspects of modern diagnosis and treatment and of the lay public in the recognition of suggestive signs of early cancer and precancerous conditions. The material contained in the handbook is authentic in character, conveniently arranged (except for the absence of an index which would have improved even so small a handbook) and while brief, is sufficiently comprehensive to serve the needs of the general practitioner for whose use it is primarily intended. This booklet is significant not so much for what it contains, useful as that is

but for the fact that it is a joint educational effort by organized medicine and organized public health in Colorado. It is one of the self-imposed programs of self-improvement which characterize the medical profession and which seem to have escaped the notice of many of its self-appointed critics. Attention is called in the introduction to the educational programs of the American Society for the Control of Cancer and its Women's Field Army, which functions in each state under the direction of the state medical society's committee on cancer. Not only as a technical contribution to cancer control in that state but as a manifestation of educational mobilization of all community forces against cancer, this booklet commands attention. Readers outside Colorado would have appreciated some statement in the pamphlet as to its availability outside the state and, if so, at what price and from what source.

**Illustrated Primer on Fractures.** Prepared by the Special Exhibit Committee on Fractures in Cooperation with the Committee on Scientific Exhibit of the American Medical Association. Fourth edition. Cloth. Price \$1. Pp. 90 with 43 illustrations. Chicago. American Medical Association 1938.

In a new format, with an interleaving of blank pages for personal notes or drawings, there has now appeared a fourth edition of the popular *Primer on Fractures*. This is the product of the Special Exhibit Committee on Fractures of the American Medical Association under the chairmanship of Kellogg Speed, printed in cooperation with the Committee on Scientific Exhibit of the Association. The new volume fits any book shelf and can be carried in an automobile pocket for ready reference. In it are found descriptions of the elementary principles of fracture treatment, including emergency care for transportation, with brief explanations of cause, ordinary displacements and X-ray appearances of many of the fractures met in general practice, all illustrated by line drawings spread through the text. Plaster of Paris bandage making and use are stressed and sage advice is given for its employment. A list of splints and materials which can be easily carried in the doctor's automobile or an ambulance is given. The committee for the American Medical Association should be congratulated on this revision for its conservative yet up-to-date instruction, its orderliness and its presentation in a form better adapted than the previous editions for carrying and handling. Every medical practitioner should be armed with this valuable *vade mecum* which conveys so much elementary yet essential information on which he may rely.

**Corpus Iconum Morborum Cutaneorum.** Collected and edited by Louis Nékam, Senator and Professor of Dermatology and Syphilology, Royal Hungarian University, Budapest. Volume 1. Parts 1, 2 and 3. Cloth. Price 194 marks. Pp. 180, 464, 928 with illustrations. Leipzig. Johann Ambrosius Barth 1938.

At the ninth International Dermatologic Congress in Budapest, Sept. 13 to 21, 1935, it was decided to make a further issue of publications devoted to pictorial representations of dermatologic conditions. It was felt that such a publication would do much to produce a universal dermatologic nomenclature, to say nothing of its educational value. Professor Nékam agreed to assume this monumental task, although he had already devoted almost his entire time for two years to ensure the success of the congress. These three volumes are the fruits of these endeavors. He has been assisted in the publication by a staff of Hungarian, as well as by several German, Italian, English and French collaborators. It is unfortunate that the lack of space precludes mentioning them by name.

Part I, a book of 180 pages, is directed to the introduction. In this work it is not the desire to present a textbook but rather a collection of examples of skin diseases with their classification and nomenclature. A morphologic as well as an etiologic classification is submitted to the reader. A valuable table of synonyms assists the reader to a clearer understanding of dermatologic terms. Instead of long descriptions of each illustration with the illustration, 115 pages are then devoted to only a few salient words about each illustration, for this monument comprises 4,566 photographs collected from between 500 and 600 dermatosyphilologists from all over the world. Part I finishes with an excellent index, an item in which the average European volume is lamentably weak.

Parts II and III are devoted to the pictorial illustrations and they are grouped so that the interested reader has an opportunity

to study many variations of the various diseases as collected from different parts of the world. In part II, of 464 pages, is found an immense collection of photographs on syphilis, the related frambesia or yaws, and tuberculosis. For the mycologist there is an enormous material furnished on mycotic diseases with illustrations of their growth, on mediums, and photomicrographs of individual types of organisms. Occupational eruptions and disorders of internal secretion are also well represented.

Part III, of 928 pages, is the zenith of the great work, if this is possible. Much material is furnished to illustrate types of parapsoriasis, a disease difficult for even the dermatologist to classify properly, lymphoblastomas and neoplasms are fully illustrated in all forms and types. There are many excellent representations of the rarer malignant diseases, Paget's disease, Bowen's disease and various nevus conditions. Cutaneous fungous diseases of animals in their relation to man are also faithfully presented in this volume. Diseases of the appendages, hair and nails are presented. Part III also presents many cutaneous disorders in colors.

These three parts of volume V of the publications of the ninth International Dermatologic Congress, and in fact each one a volume in itself, are a monument to Professor Nékám, to the Hungarian school of dermatology and to Hungary itself. The cost of the preparation and production must have been enormous, to say nothing of the weeks and months devoted to it by what must have been loving hands, or it would never have been brought to fruition. Professor Nékám himself has furnished almost one fourth of the illustrations—the ones on fungi being notable.

These volumes are a credit to international dermatology, which knows no national boundaries. The illustrations are almost invariably of a high order and are printed on a fine glossy paper that takes them well. There are enough of them on each disease to make the volumes of highly educational value not only for the specialist but also for the general medical man interested in dermatology. An atlas of cutaneous diseases of this monumental type has never been attempted before, and it will be many years before any one individual so fortunately situated as Professor Nékám and his school of dermatology will attempt to emulate it. The printer and illustrator have done their work well, the type is clear, the format is excellent, and the binding, while not elaborate, is designed to wear well.

The three volumes are unhesitatingly recommended to medical schools, libraries, dermatosyphilologists and medical men in general.

**The Home Book of Medicine** By David Polowe M.D. Cloth Price \$2.75 1 p. 581 with 13 plates New York Greenberg, Publisher Inc. 1938

This book is an attempt at one of the most difficult feats in medical writing for the public, the production of a home book containing sound advice on what to do before the doctor comes, or what to do when there is no possibility that a doctor can be procured. In situations in which a doctor is readily available, such a book should limit itself to general questions of hygiene and healthy living, and perhaps emergency first aid. In that case it would be useless in remote places where medical aid is needed and there is no doctor within miles, or no way to communicate with a doctor in time. The old-time doctor book had detailed instructions for treating the sick without medical advice, the modern book of this type should eschew such suggestions. The volume under review gives the impression of a medical text somewhat written down to the supposedly lower intellectual level of the lay reader. Such writing misses the point. The lay reader is not less intelligent, by and large, than the medical reader. He is simply less well equipped with a background for the comprehension of medical literature. Merely setting before such a reader a somewhat simplified medical book does nothing for him except through its recital of symptoms to tempt him to self diagnosis and through the detailed outline of treatment to suggest that he and not his doctor should be responsible for therapy. To be specific, the chapters on immunity contain much material, such as that on agglutinins and opsonins, of no interest or importance to the lay reader and leave him confused rather than enlightened. The discussion of debridement under tetanus is out of place in a book for the layman. The anatomic chapters in the front of the book are inadequate but at the same time

contain much material of no interest to the nonmedical reader. The illustrations are obviously transplanted from medical text books. What does the lay reader know or care about the bones of the lower extremity, that there are sixty-two bones in the lower extremity, and the exact relationship of the sutures in the skull? The section on the "insanities" is sketchy, inaccurate and totally inadequate. The implication that cancer is a term applicable to all tumors benign as well as malignant, is unjustifiable and will go far to undo the efforts of medical societies and women's clubs, to dispel the unthinking fear of cancer and to cause people to deal boldly with precancerous states. Such subjects as fibro-neuromas, ganglionic cysts, "surgical conditions of the bones" and surgery of the nerves and blood vessels are unsuitable for discussion in such a book, the adequacy of the material itself can be imagined from the fact that the chapter on surgical conditions in adults takes just nine pages. These are but a few points among many. The book contains much good advice and many useful facts. This is readily apparent to the physician, but the book is not intended for the physician. Considering the book as a whole, one is forced to the conclusion that it will do little good in the ordinary home and may do much harm.

**The British Encyclopaedia of Medical Practice including Medicine Surgery Obstetrics Gynaecology and Other Special Subjects** Under the General Editorship of Sir Humphry Rolleston Bt. G.C.V.O. K.C.B. M.D. Volume VIII Leukaemia to Mucous Colic. Cloth Price \$1.75 Pp. 712 with 65 illustrations including 13 plates London & Toronto Butterworth & Co. (Publishers) Ltd. 1938

Volume VIII of the Encyclopaedia of Medical Practice proceeds from "leukaemia" to "mucous colic." It is interesting that these two terms should differ so greatly from the American spelling and usage of the same terms. En route from "leukemia" to "mucous colic" are such interesting main headings as the "lipoidoses," "liver diseases," "lung diseases," "the lymphatic glands," "malignancy," "massage," "meningitis," "mental diseases," "metabolism," "mouth diseases" and "motor neuron diseases." The cooperating writers are among the leaders of British medicine and the writing throughout shows the effect of fine editorial attention. Volume VIII is fully up to the standard of the excellent volumes which have preceded it.

**Sauglingskrankheiten** von Professor Dr. H. Finkelstein Fourth edition. Cloth Pp. 890 with 204 illustrations Amsterdam Elsevier 1938

This edition retains in general form the outline of the previous editions. The various chapters and subjects have, in the main, been revised, rewritten and brought down to date. A chapter on rickets has been added and the older chapters on vitamin deficiencies have been extensively revised. Some new tables have been appended and several color plates on rickets and the skin diseases have been added. The author has incorporated his latest researches on water balance in the chapter on nutritional disturbances and he has included in an outstanding chapter on eczema much of his experimental work on this subject. The literature is brought through the end of 1937. With the advent of the third edition, in 1924, it seemed that the author's book had reached the acme of perfection. Nevertheless in the present edition he has improved on previous editions of his masterful writings. Heinrich Finkelstein's work contains a storehouse of knowledge, replete with the author's large and unique experience. The larger type used in the fourth edition, as well as a better quality of paper, greatly improve the physical format.

**The Conquest of Cholera America's Greatest Scourge** By J. S. Chambers M.D. Professor of Hygiene and Public Health and Director of Student Health Service University of Kentucky. Cloth Price \$1.75 Pp. 366 with 40 illustrations New York Macmillan Company 1938

A most fascinating story that is as interesting as it is authoritative. There will be few readers who can lay this book aside until they have read the last page. The book deals with the epidemic of Asiatic cholera in the United States from its outbreak in 1832 to its conquest in 1892. The reader is taken in word, picture and map along the path of the disease from its first outbreak along the Atlantic coast to the interior valleys and the epidemic in the blue grass country. The second invasion and the gold rush of '49 furnish further thrilling chapters. The contributions of foreign and American physicians and allied workers are discussed and each is given the place and prominence deserved. This volume is a notable contribution to medical history.

**The Clinical Examination of the Nervous System** By C H Monrad Krohn MD FRCP Professor of Medicine in the Royal Frederick University Oslo Seventh edition Cloth Price \$3 Pp 319 with 111 illustrations New York Paul B Hoeber Inc 1938

In the review of the fifth edition of this book it was stated that the book could not be praised too highly, that it contains everything essential and states it in a clear manner, and that nonessentials are omitted. With seven editions in seventeen years its popularity is amply proved. The number of illustrations, mostly inserts and well chosen is greater than in previous editions. So much also has been added to the text that the maximum desirable size for a book of this kind has been reached. When a new edition becomes necessary the author should condense the material and decrease rather than increase the size of the book. It is extremely helpful for students, general practitioners and neurologists alike.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Malpractice Liability of a Corporation for Malpractice**—The New Castle Clinic was a corporation the directors of which were licensed physicians. It was described as "an operating force for a hospital" located in a building owned by the Clinic Realty Company. It employed the help in the building and collected all fees and charges for services rendered by the physicians who had offices in the building. The appellee injured his leg in an automobile accident and was taken to the clinic building. There the appellant physician, a director of the corporation, diagnosed the injury as a dislocation of the hip, which was reduced. The patient was then placed on a cot and returned in an ambulance to his home. Subsequently, it was alleged, other physicians discovered that there had been a fracture of the pelvis and hip socket. Permanent lameness and partial disability resulted. The patient then sued the clinic corporation and the appellant physician. The trial court gave judgment for the patient, and the case came before the Supreme Court of Indiana for review.

The complaint was based on the theory that the corporation was engaged in the practice of medicine and surgery and that it contracted to diagnose and treat the patient's injury. But, said the court, in Indiana it is unlawful for a corporation to practice medicine. Any contract, therefore, made in the name of a corporation, purporting to bind it to diagnose or treat ailments or diseases, is not only ultra vires but unlawful and against public policy. The right to practice medicine and surgery under a license by the state is a personal privilege. It cannot be delegated and a corporation or other unlicensed person may not engage in the practice of medicine by employing one who is licensed to do the things which constitute the practice of medicine.

If a licensed physician employs assistants who work under his direction as assistants in the practice of medicine or surgery, the rule of respondeat superior applies and there are cases, the court said holding that a corporation which has contracted to diagnose or treat disease is estopped from denying that a physician is its agent. It is undoubtedly true that corporations are liable under their ultra vires executed or partially executed contracts, and for the negligence of their agents and servants thereunder, where the contracts are within the apparent scope of their authority or where the other party to the contract could not be presumed to be cognizant of the invalidity. Difficulty arises however in applying the estoppel doctrine without doing violence to sound principle where the contracts involved are not only ultra vires but unlawful as against public policy. The complaint in the present case charged that the corporation contracted to diagnose and treat the plaintiff's ailments that it was negligent in performing the contract. The defense is that the corporation made no such contract because it had no power to make it. An estoppel would deny the corporation the right to assert illegality, notwithstanding there were no facts involved concerning which the patient was deceived or was without knowledge. There can be no estoppel, in the opinion of the

court, on such a basis. Since the corporation could not legally practice medicine, the patient was bound to know that whoever treated him was not acting for the corporation.

The patient came to the hospital, talked to the appellant physician and was treated by him with the assistance of two other physicians. Nothing was said as to whether the services were to be rendered by the physician or by the corporation. The physician was a stockholder and director in the corporation. The facts justify the conclusion that the corporation charged and collected for the use of its hospital facilities and equipment, and for furnishing the services of licensed and qualified physicians and surgeons. Under such a contract the duty of the corporation, in respect to the physicians or surgeons, would be complied with by using reasonable and ordinary care to employ reasonably qualified, reputable, licensed physicians. In such a case the physicians or surgeons are independent contractors. There was evidence from which the jury was justified in believing that, at the time the patient was treated by the appellant physician, there was a fracture of the hip joint and of the pelvis and that these fractures would have been disclosed by a reasonably careful examination of a roentgenogram, taken with ordinary care, or by a reasonably careful fluoroscopic examination. The roentgenogram taken by the appellant physician at the time of the treatment was destroyed because, he testified, he had spoiled it and it was no good. The appellant physician examined a roentgenogram taken by physicians who subsequently treated the appellee and admitted that it showed a fracture of the pelvis and that a roentgenogram taken an hour after the accident should have shown the same thing if the fracture were then present. The jury may have concluded, the court said, that the fracture was there and that the roentgenogram taken by the appellant physician would have disclosed it if taken and developed and examined with that degree of care which might reasonably have been expected from a reasonably careful physician under the standards prevailing at the time in the community. In the opinion of the court, the evidence was sufficient to justify the verdict against the appellant physician.

The judgment of the trial court against the physician was affirmed and the judgment against the corporation, for the reasons stated, was reversed.—*Ittman et al v Baker (Ind)* 15 N E (2d) 365

**Autopsies Liability for Autopsy Performed at Request of Coroner**—The plaintiff sued to recover damages for an unauthorized autopsy performed on his minor son. The county coroner, three physicians who performed the autopsy and an incorporated funeral home in which the autopsy was performed were joined as parties defendant. At the close of the plaintiff's evidence, judgment of nonsuit as to all defendants was entered and the plaintiff appealed to the Supreme Court of North Carolina.

The body of the plaintiff's minor son was discovered in a swimming pool in Greensboro, apparently drowned. The plaintiff lived in Wilmington. None of the next of kin of the deceased boy was in the county in which his body was found. The coroner was called in, and he, on finding no water in the lungs and the neck unbroken had the body removed to the defendant funeral home and called in the three defendant physicians to determine the cause of death. The evidence showed that the autopsy was carefully performed and that there was no mutilation of the body other than an incision 16 inches (41 cm) long, carefully closed and sewn which did not show when the body was clothed for burial. The marks on the body, according to the evidence, were but little more than those which would have been rendered necessary in the ordinary process of embalming. The autopsy revealed that the death was due to an acute heart attack. It was testified that the coroner had said "he had the autopsy performed to determine the cause of death, that he had no suspicion of foul play that no inquest was held." Admittedly no permission from the plaintiff nor any of the deceased's kin was asked or obtained. The plaintiff testified that he would not have given his consent if it had been requested and that the knowledge of the autopsy on the body of his son shocked and unnerved him equally with the news of his death.

The duties and powers of a coroner, the court said, are prescribed by law. No authority is given the coroner, in cases in which he does not suspect foul play and in which no inquest is held or jury summoned to cause on his own initiative an

autopsy to be performed merely to ascertain the cause of death of a person. The statute authorizes an investigation "whenever it appears that the deceased probably came to his death by the criminal act or default of some person," and in such case empowers the coroner "to summon a physician or surgeon and to cause him to make such examination as may be necessary whenever it appears to such coroner is proper to have such examination made." Furthermore, the court continued, the right to perform an autopsy in North Carolina is expressly limited by chapter 209, Acts of 1933, as follows:

The right to perform an autopsy upon the dead body of a human being shall be limited to cases specially provided by statute or by direction or will of the deceased cases where a coroner or the majority of a coroner's jury deem it necessary upon an inquest to have such an autopsy and cases where the husband or wife or one of the next of kin or nearest known relative or other person charged by law with the duty of burial in the order named and as known shall authorize such examination or autopsy.

It follows, said the court that an unauthorized autopsy to determine the cause of death when foul play is not suspected, though ordered by the coroner under color of his office, is in violation of the rights of the next of kin of the deceased and that the coroner is not protected by the official capacity in which he purports to act. The duty to ascertain the limits of his authority and to observe the law, particularly when the rights of others were affected was incumbent on the coroner. The general rule is that when an officer goes outside the scope of his duty he is not entitled to protection on account of his office but is liable for his acts like any private individual.

It also follows, the court said, that the physicians who performed the autopsy at the request of the coroner, on his request that this be done merely to determine the cause of death and without the consent of the next of kin, are equally unprotected from liability for an unauthorized invasion of the rights of those injuriously affected.

There was no testimony that the agents of the defendant funeral home did more than fail to offer objection to the action of the coroner by whom the body was brought to its home, and the court could not perceive how this evidence could be held sufficient to impose liability for an unauthorized autopsy performed by others and with which it had nothing to do.

The court concluded, therefore, that the judgment of nonsuit as to the defendant funeral home should be affirmed and reversed as to the other defendants.—*Gungahons v. Simpson et al* (N C) 197 S E 163

**Workmen's Compensation Act Extent of Loss of Vision, Use of Glasses**—The workman injured his right eye during the course of employment resulting in a 20/100 vision in that eye. With the aid of glasses the vision was normal. Liability was admitted by the employer and compensation was paid for several months. Then the employer's insurer served notice of discontinuance of payments and the workman instituted proceedings under the workmen's compensation act. The industrial commission affirmed an award of a referee based on a 75 per cent permanent partial disability of the right eye and the employer petitioned the Supreme Court of Minnesota for a writ of certiorari.

The question before the court was whether, in computing an award for a fractional loss of vision, such award should be based on the percentage of loss without the use of glasses or whether it should be based on the percentage of loss when such vision is aided by means of a corrective lens. Vision, the court pointed out, is measured by scientific methods. A test recognized by the medical profession for measuring visual acuity is known as the Snellen test and this test is used by the industrial commission as a standard in rating losses of vision. The court could find nothing in the workmen's compensation act to indicate the intention on the part of the legislature that disability after correction is to be the basis for awarding compensation where there has been an eye injury. If such had been the intention the act would have been drafted so to provide. The court could see no more logic in holding that the legislature intended to base disability in any eye case after correction than in holding that in a leg or arm case compensation should be awarded on the extent of disability after the attachment of a brace or any other appliance. The fact that glasses are required to restore vision was to the court evidence of the permanency of the injury and, whether artificial means may partially or

even wholly restore sight, it nevertheless cannot obliterate the effect of the accident causing the injury.

The court was not prepared to say that other tests may not be devised that will replace and improve the so called Snellen test and afford the medical profession and the industrial commission a more nearly perfect way of rating visual acuity. Until such a method presents itself, however, and is recognized by the medical profession as being as good or better, the commission, in the opinion of the court, was justified in using the Snellen test.

The decision of the industrial commission for the workman was therefore affirmed.—*Livingston v. St. Paul Hydraulic Hoist Co* (Minn.), 279 N W 829

**Hospitals Detention of Patients for Nonpayment of Bills**—The plaintiff sued the defendant hospital and its manager to recover damages for unlawfully detaining her in the hospital. At the close of the evidence the action against the hospital was dismissed but judgment was rendered against the manager. The plaintiff thereupon appealed to the Supreme Court of North Carolina.

The plaintiff testified that she entered the hospital for treatment December 7 and planned to go home December 14, that the manager, on being told that she did not have the money to pay her bill, informed her that she could not leave the hospital until the doctor's bill and the hospital bill were paid in full. She believed, she testified, what the manager of the hospital told her, and her departure from the hospital was thereby delayed for several days. No one undertook to restrain her, however, by any kind of force.

False imprisonment, said the Supreme Court, is the illegal restraint of one's person against one's will. It generally includes an assault and battery and always at least, a technical assault. Involuntary restraint and its unlawfulness are the two essential elements of the offense. When no force or violence is actually used, the submission must be to a reasonably apprehended force. The circumstance merely that one considers himself restrained in person is not sufficient to constitute a false imprisonment unless there is in fact a reasonable ground to apprehend a resort to force on an attempt to assert one's liberty. To constitute false imprisonment there must be an exercise of force, or expressed or implied threat of force, by which in fact the person is deprived of his liberty and compelled to remain where he does not wish to remain. The restraint of the person may be caused by threats, as well as by actual force, if the words are such as to induce a reasonable apprehension of force.

Applying these principles of law to the plaintiff's testimony, the court said, it was apparent that neither force nor threat of force was employed to prevent her from leaving the hospital, and though she testified that she thought she could not leave the hospital until the bill was paid nevertheless, without paying the bill, she departed from the hospital without restraint by word or act. For these reasons, the court concluded that the judgment of nonsuit as to the hospital was properly entered. That judgment was therefore affirmed.—*Hoffman v. Clinic Hospital Inc* (N C), 197 S E 161

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Unusual Forms of Atrioventricular Rhythms**—In the last two years Katz and Kaplan have encountered four cases of unusual atrioventricular rhythm. In a case in which there were carotid sinus hyperirritability and reflex stimulation the differentiation of reciprocal rhythm and the closely resembling condition of sinus bradycardia, nodal escape and interference dissociation with pseudoreciprocal rhythm could be demonstrated. The electrocardiograms of two patients showed variations in the PR (RP) interval, but the RR interval remained constant. The electrocardiogram of another patient showed a short PR interval and a prolonged QRS complex, with a shift in the pacemaker to the sino auricular node following an ectopic ventricular beat, from a patient with severe chronic cardiac disease.

**Environmental Temperatures and Heart Disease**—Bean and Mills studied the influence of temperature on coronary thrombosis and cardiac failure by a review of the literature giving the months in which the acute attacks occurred and by a survey of the records of all patients with noninfectious cardiac failure who were admitted to the Cincinnati General Hospital from Jan 1, 1920, through Dec 31, 1937. The time of onset of the acute attacks in these records was mentioned in 278 instances of 8673 consecutive necropsies. The data obtained show a marked seasonal swing in the frequency of attacks of coronary occlusion. They are almost twice as frequent in winter as in summer. An even greater winter peak is found in the frequency of onsets of noninfectious arteriosclerotic cardiac failure, which occurred about two and a half times more frequently in winter than in summer. Just why syphilitic cardiac failures pursue a course independent of temperature level is not entirely clear. It is probably because syphilitic cardiac disease progresses at a more steady and rapid rate, and therefore the effects of changing temperature produce a less noticeable effect. Greater frequency of infections, especially of the respiratory tract and heightened general body metabolism probably act together to increase the winter hazards of existence for cardiac patients, while the calm warmth of summer brings a period of relative safety. In stormy weather, fluctuations in temperature may produce a strain by means of little known vasomotor reflexes as in angina pectoris while walking in wind or cold weather. Migration out of northern cold and storms either temporarily or permanently is strongly indicated for every patient of limited cardiac reserve.

**Equine Encephalomyelitis in Man**—Feemster gives a chronologic review of the 1938 outbreak in Massachusetts of encephalitis in horse and man due to the eastern virus of equine encephalomyelitis. He states that it is impossible at present to estimate how many human cases of encephalitis due to the equine virus have occurred in the state during the outbreak. Some thirty-eight cases have been under investigation. Thus far the virus has been isolated in eight cases at postmortem examination. If the mosquito is the vector of the natural infection in horses, the spread of the disease in the state can easily be accounted for once a case is introduced. Some of the cases under investigation will have to be eliminated either because another diagnosis will be established or because evidence will not be sufficient to warrant the diagnosis of encephalitis due to the equine virus. As early as 1931 Meyer suggested the possibility of human beings contracting the equine disease. The disease in the severer form is sufficiently different from the usual varieties of encephalitis to be recognized clinically. If some of the milder cases under investigation prove to be due to the same virus, and particularly if the existence of subclinical infections can be established, the recognition of all cases will be difficult unless laboratory means of verifying the diagnosis can be found. The onset in infants was sudden, accompanied by fever, irritability or drowsiness, cyanosis and convulsions. In older children and in the one adult the symptoms were of slower onset, from four to ten days. Headache, frontal in character, and dizziness were the first complaints in the older patients. All patients were semicomatose to comatose on admission and the majority showed continued tremors or muscular twitchings. Rigidity of the neck was a constant feature, as was a tense anterior fontanel in the infants. The suppression of the cutaneous reflexes was constant in the comatose patients, while the Kernig and kindred signs varied markedly. The pupils reacted sluggishly to light. The temperature was invariably high, from 102 to 104 F, and in the fatal cases (twenty-five of the thirty-eight) continued to rise. When recovery took place the fever fell by lysis, becoming normal in four or five days. The spinal fluid showed increased pressure. When the patient lived for more than two or three days there was a drop in both the spinal fluid and leukocyte counts, with a change to the mononuclear type of cell. Convulsions and muscular twitchings marked the course of the disease. In the infants a peculiar edema developed about the eyes and in the upper extremities. Cyanosis was marked in all cases. Deep coma from which the majority of patients never aroused developed shortly after admission. Some cases suspected of being due to the virus have ended in complete recovery but it appears that others will show paralyses, mental changes and other permanent residuals. A number of problems with regard to the disease await elucidation. It is necessary to know whether other reservoirs besides the horse are important. It yet remains to be demonstrated satisfactorily that the mosquito transmits the natural infection among horses. The importance of other insects, especially the recently incriminated tick, as vectors of the disease awaits investigation. The need of having all cases of encephalitis reported to health departments is emphasized by the presence of the equine infections in human beings. The attack rate among horses was low (33 per cent) but the case fatality was high (more than 90 per cent).

**Typhoid Carrier Incidence in Mississippi**—Gray presents the results of a random typhoid carrier survey. It involved 18,577 people in sixteen counties in Mississippi. 1,547 of whom gave a history of having had typhoid as diagnosed by physicians. Those surveyed were classified by age and race as to the total

number in each group giving a history of typhoid. The percentages thus obtained were applied to the total age and race group populations of the state to find the total number of people now living in Mississippi with a history of typhoid. According to these calculations there are 183,230 people in the state with such a history. Of 244 persons with proved typhoid in Mississippi eight or 3.27 per cent of the group, became permanent carriers and were excreting *Bacillus typhosus* more than one year after onset. Applying this percentage to the total of recovered persons living in the state, 183,230 there are about 5,991 typhoid carriers in the state at present, or 288 carriers per hundred thousand of population.

### Roentgen Classification and Diagnosis of Silicosis—

Mitz classified, according to the criteria of Sampson, 167 veterans hospitalized for various types of silicosis. The classification is based on the x-ray observations. As the x-ray study of these cases progressed, it was observed that there was a paucity of information regarding the occupational history of the individual patients. In many instances short references were made to a single occupation of the silicotic veterans without indicating the other occupations in which they might have been engaged, the hours of employment, the concentration of the dust particles and other points necessary to establish a diagnosis of silicosis. The inference drawn from a careful study of the roentgenograms of these patients is that the essential requirement in making a diagnosis of silicosis is the correlation of the clinical history, physical changes, a detailed occupational history and the x-ray observations. It is unsafe to depend on any of these data singly; they must be correlated and a decision reached only after a careful study is made of all the data available in each case. The inhalation of silica dust produces certain x-ray changes characterized by an accentuation of the linear markings of the lungs. Such changes are not specific for silicosis, since they are also found in subjects who give a history of inhaling nonsilicicous dusts. Inflammatory processes, infections of various kinds and abnormal circulatory states may also produce x-ray densities which simulate the preliminary x-ray changes, accentuated linear markings found in the early stages of silicosis. It is only when fibrotic nodulations are found in the parenchyma and are present on the roentgenograms and there is a history of employment in a silicicous occupation together with evidence of clinical and physical signs of silicosis, that one is justified in arriving at a diagnosis of this disease. The roentgenologic classification of silicotic disease in the group of veterans according to the terminology of Sampson showed that 29.9 per cent

were classified as first, second or third degree silicosis, 11.4 per cent as silicosis with nontuberculous infection, 42.5 per cent as silicosis with tuberculosis and 15.6 per cent as silicotuberculosis. One case was diagnosed as asbestosis. The most common x-ray observations in silicosis with infection in the order of frequency were mottling, widening of the mediastinum, diffuse haze or shadow extending inward from the lateral pleura of the mid portion of the lungs, prominence of the linear markings, beading along the course of the linear markings, emphysema, discrete nodule formation and a combination of discrete and confluent nodular formation. Those in silicosis with tuberculosis were fuzziness and haziness of the outline of the silicotic nodule, fibrosis, caseation, mottling, emphysema, pleurisy and cavitation. In silicotuberculosis the most frequent x-ray observations were fuzziness and haziness of the outline of the silicotic nodule, fibrosis, mottling, caseation, emphysema, pleurisy and cavitation. Silicosis is difficult to diagnose when emphysema is a coexistent condition. Owing to its presence, certain of the diagnostic signs of silicosis may become obscured.

**Bilateral Pleural Collections of Fluid**—The simultaneous occurrence of a transudate on one side and exudate on the other is rare. Packard and Gordon encountered three such cases in a series of 228 patients with pleural effusions admitted to the Chest Department of the Jefferson Hospital during the last fourteen years. They had been receiving artificial pneumothorax treatments for unilateral tuberculosis, the effusions having developed as a complication on the treated side, the transudates occurred subsequently in the opposite pleural cavity, two without apparent cause. The possible mechanism in one case is discussed. While the etiology of this case is undoubtedly a factor in creating the background for the transudate in the right pleural cavity, the mechanism was essentially physiologic. It appeared that pulling and rotating of the mediastinum were caused by the artificially induced high negative intrapleural pressure on the left side. As a result blood and fluid were sucked from the fine capillaries areas of new growth beneath the pleura and other tissues into the right pleural cavity. Undoubtedly the pumping action of the paradoxically moving diaphragm as a secondary mechanism was largely responsible for aggravating the mediastinal condition. Thus it would seem that the greatest care should be taken in expanding forcefully any lung that has been contracted for a long time because of the possible influence on the opposite pleural cavity. In the management of bilateral collections of fluid the principles of hydrodynamics and aerodynamics are important. The combination of pneumothorax and thoracentesis seems desirable.

**Malaria Cured with Sulfanilamide**—Coggeshall effected a cure with sulfanilamide for Plasmodium knowlesi malaria in rhesus monkeys. The absence of demonstrable parasites in the blood smears after treatment with sulfanilamide, the inability to transfer infection by the subinoculation of blood or spleen to susceptible animals and the failure of the splenectomized monkeys to relapse is evidence that the infection was eliminated. As a final test for the eradication of infection all monkeys were reinoculated intraperitoneally with one million parasites. The

length of time after treatment varied from twenty-nine to ninety-one days. Each inoculation resulted in an infection followed by recovery from the acute attack in the nonsplenectomized monkeys. The three which had been splenectomized had severe and rapidly fatal infections. All the monkeys became infected when reinoculated. Only the three monkeys which were splenectomized died as the result of their infections. The fact that the remaining seven monkeys had mild infections followed by spontaneous recovery was indicative of a partial residual immunity in the absence of a latent infection.

**Epileptogenic Cortical Scars**—The surgical treatment of traumatic epilepsy is at present directed toward removal of the irritative focus. This German points out, requires accurate preoperative localization of the lesion. His report is based on the results in twenty-nine cases after intervals of from one to eight and a half years following cerebral surgical procedures for the treatment of epilepsy. In nineteen of the twenty-nine cases there was complete or partial relief from convulsive symptoms. Frequent major attacks continued in nine cases. The standard operative procedure of complete excision was followed in fourteen of the sixteen cases in which there were cortical scars. The results were satisfactory for eleven patients, four being completely relieved from convulsions and six definitely improved. Frequent major attacks continued in three and one patient died. Of the two remaining cases, lysis of meningeal adhesions was successful in one and failed in the other. Of the four cases of porencephaly, simple uncapping and lysis of adhesions were successful in two and failed in two. The operative procedures were somewhat more varied in the nine cases in which there was cortical degeneration. Complete excision was carried out in three cases with success in two. Incomplete excision was carried out in four cases with success in one and improvement in three. Lysis of meningeal adhesions gave only temporary relief (for one year) in one instance, and excision of motor areas (for the face and arm) failed to control convulsions in one. In spite of the lack of standardization of surgical procedures in the cases of degenerative lesions, favorable results were obtained in six of the nine cases. From these results it is evident that the type of surgical procedure, though important is not the only determining factor in prognosis. In the combined series a second operation with complete excision was performed in two cases because of failure following partial extirpation. The radical procedure was successful in one case that of a degenerative lesion and failed in the other that of a cortical scar. The type of pathologic lesion though probably not without significance was of only slight aid in establishing a prognosis. From a prognostic standpoint the age of the patient failed to show any significant correlation. The temporal span during which convulsive episodes had been present showed a definite prognostic correlation. In seven of the eleven cases of cortical scar in which results were satisfactory the duration of convulsions was not more than two years while in the four failures convulsions were present for more than two years. In four of the six cases of degeneration in which the results were satisfactory convulsions had been present for three years or less while in two of

the three cases of failure convulsions had occurred for more than three years. The group of cases of porencephaly was too small to justify statistical analysis. The maximal frequency of convulsions appeared to have no significant relation to prognosis. Analysis of the anatomic location of the lesion gave little evidence of prognostic significance. The parietal region was found to be the most frequent single site of all types of lesions, and the greatest proportion of satisfactory results was obtained in the group of parietal lesions. A definite traumatic basis was present in thirteen cases, while injury at birth was apparently responsible in seven cases. Previous cerebral operation was the presumptive factor in one case and thrombosis in another. In two cases porencephaly was probably related to prenatal factors, and in one case it was perhaps secondary to infection. No relation could be established between etiologic factors and prognosis. The pathologic lesions ranged from simple degeneration of ganglion cells, through degeneration with glial proliferation, to dense glial or fibrous scars. Definite glial scars were seen in the walls of porencephalic cavities.

**Physical Development in Mongolism**—Benda finds, after the clinical examination of 120 persons with mongolism, that the condition is present at birth. Therefore the influence which leads to the condition of mongolism is predominant during the prenatal period. After birth there are residuals of such an influence, and one finds remarkable retardation in development. Many mongoloid children die in the first years of life. If the child survives the first few years, he adjusts himself fairly well to the biologic conditions of life. Growth is slow but at a low normal level during the first nine years. Increase in height ceases early, and after the fifteenth year few mongoloid persons show further growth. Mongoloid children are usually underweight during the first two years of life. Many become overweight after the fifth year and dystrophia adiposogenitalis is frequent after puberty. The mongoloid skull is not microcephalic at birth but shows lack of growth. All mongoloid children appear microcephalic after six months. Persons with mongolism usually show early ossification and fusion of the epiphyseal lines, even when the condition is complicated by rickets. The investigation has proved that mongoloid deficiency is not a racial mutation but the result of a disturbance which becomes apparent during fetal development. The mongoloid appearance is due to a peculiar formation of the skull and has nothing to do with the Mongolian race or any kind of atavistic regression.

**Diabetes Mellitus and Hyperthyroidism**—When diabetes mellitus and hyperthyroidism coexist Foster and Lowrie believe that the diagnosis of diabetes mellitus is usually made first. Certain features during the course of the illness arouse suspicion

that thyroid disease may be a complicating factor. An inability to control the blood sugar and glycosuria with what seems to be a suitable diet and insulin dosage or the failure of a patient to hold his weight or to gain while consuming a diet adequate for either circumstance is significant. These patients also are prone to develop acidosis, especially if they are losing weight or are undernourished. A rapid pulse, intolerance to heat or bedclothes, restlessness, flushing, apprehension, a moist skin and eye signs are all aids to a correct diagnosis, particularly in the younger patient. Forty-two cases of diabetes associated with hyperthyroidism were found in the admissions to the Henry Ford Hospital from 1925 to 1938. During this period there were 214,223 new cases examined. Diabetes was present in 1,616 of these and a total of 1,607 operations for hyperthyroidism were done. Nine patients have died. They had an average survival period of four years and one month. Vascular disease was a primary or complicating factor in all the deaths. Toxic adenoma was present in six. Evidence is presented which would indicate that following thyroidectomy the carbohydrate metabolism was improved. The authors believe that the diagnosis of hyperthyroidism as a complication of diabetes mellitus is being overlooked. When hyperthyroidism is complicating diabetes mellitus, thyroidectomy is indicated. Vascular disease associated with hypertension, since insulin has been available, constitutes the major cause of death in this group. Acidosis is common but can be successfully combated by a high carbohydrate diet and adequate insulin.

**Testosterone Propionate in Functional Bleeding**—Geist and his colleagues used testosterone propionate in the treatment of twenty-five women with functional uterine bleeding. The bleeding was rapidly controlled in all but two of the cases. This improvement was correlated with definite changes in the endometrium, as revealed by suction biopsies performed at intervals before, during and after treatment. In all but four of the women there was no palpable organic disease. Small intramural myomas were present in these four. There were thirteen cases of menorrhagia, five of metrorrhagia and seven of menorrhagia with polymenorrhea. The ages of the patients varied from 24 to 39 years. The duration of abnormal bleeding varied from two months to ten years, with an average of two years. The monthly dosage varied from 300 to 1,000 mg. of testosterone propionate. The highest dosage given any single patient was 2,150 mg. over a period of three months. The testosterone propionate was administered intramuscularly in sesame oil in doses of from 5 to 100 mg. The intervals between doses are determined individually. Normal menses were established in eighteen cases and amenorrhea of one to five months in five. Endometrial biopsies performed during and after the period of testosterone propionate administration revealed disappearance of the secretory phase and inhibition of the proliferative phase, often with regression to the hypoplastic or atrophic state. Following the discontinuation of therapy, the inhibitory effects on the endometrium gradually disappear and normal estrogen and progesterone effects reappear. The authors suggest that the changes in the endometrium following testosterone propionate therapy are the end results of a primary inhibition of the gonadotropic factors of the hypophysis, causing suppression of the ovarian cycle, with consequent cessation of estrogen and progesterone production.

**Treatment of Acne Vulgaris with Testosterone Propionate**—Molitch selected twenty-two young men with acne vulgaris, otherwise healthy for his study. The lesions varied from the mildest to the most severe forms. All the subjects received three weekly intramuscular injections without any local treatment, internal medication or change of diet. Twelve of the patients received injections of the testosterone in sesame oil, whereas the remainder were given only sesame oil. No local or systemic reactions occurred in either group. The treated group was given injections for three months, the dose for the first month was 5 mg. for the second month 10 mg. and for the third month 25 mg. The control group received 1 cc. of sesame oil at each injection. About the same degree of improvement (from 50 to 60 per cent) occurred in the two groups. Seven additional men were treated locally with an ointment containing testosterone propionate with similar results. It is possible that acne vulgaris may be relieved by this product if an associated

hypogonadism is present. The high percentage of improvement obtained in both groups suggests that a definite psychogenic element was present in the subjects. No increase in the incidence of nocturnal emissions or erections was noted.

**Detection of the Virus of Poliomyelitis**—Kramer and his co-workers recovered four strains of poliomyelitis virus from the nasal washings and feces of human beings and one strain from a monkey killed at the height of the disease. Of the four human strains the first was isolated from the feces of a 14 year old child seven days after the onset of illness, the second strain from the nasal washings of a 6½ year old child five days after the onset of illness and the third and fourth strains from the same patient, a 2½ year old child, nine days after the onset of illness. The single monkey strain was isolated from the upper intestinal segment. The detection of the virus in the nasal washings of two additional patients during convalescence lends further support to the authors' belief that the virus of poliomyelitis is spread by human contact. The recovery of the virus from the feces indicates that the virus withstands the gastric acidity which under normal physiologic conditions tends to keep gastric contents relatively free of bacteria and that improper disposal of feces from patients with poliomyelitis may have serious consequences to the public health, particularly in smaller communities.

munities, in which inadequate sewage disposal may result in contamination of surrounding beaches or even local water systems

**Action of Snake Venoms**—Duran-Reynals tested the spreading factor in snake venom by mixing 0.5 cc of different dilutions of venom with 0.25 cc of diluted India ink and injecting this into one flank of a rabbit. On the opposite side 0.5 cc of saline solution in place of the venom was injected. It was found that the venom of several species of poisonous snakes acts to spread India ink through the skin. The spreading factor is most abundant in the venom of the Viperidae (rattlesnake) family and relatively scant in the venom of Colubridae (proteroglyphs (cobras) family and it is absent from toad venom. Extracts of the supralabial glands of harmless snakes contain only negligible amounts of the factor. Rattlesnake venom heated at from 65 to 100 C loses a large proportion of its toxicity but retains the ability to spread India ink. Rattlesnake venom that has lost its toxicity on standing or on heating markedly enhances the infection produced by bacterial or virus suspension in the rabbit skin. Antivenom serum inactivates both the toxic and the spreading factors of venom.

**Precipitinogen in Serum Prior to Rheumatism**—The evolution of a rheumatic attack involves three distinct clinical phases: (1) an acute respiratory infection usually of not more than three days' duration, (2) an afebrile symptom-free period which may vary somewhat but commonly lasts fourteen days, and (3) the period of acute rheumatism composed of one or more cycles of activity. Coburn and Pauli observed that serums taken at the height of an acute rheumatic attack showed definite precipitation with serums taken within a week before the onset of symptoms. Pairs of serums which reacted with each other were then tested separately against other serums from the same patient. The results of these observations showed that precipitation occurred only between phase 2 and phase 3 serums. In at least six other cases known positive phase 2 serums were tested against each other and known positive phase 3 serums were also tested in pairs. No reactions occurred between any of these combinations. This limitation of the reaction to the combination of phases 2 and 3 furnished a plan on which extensive investigations were based. Serums from phase 2 (and also, when available, from phase 1) were tested as potential antigens against serums from phase 3. A precipitin reaction occurred between serums taken just before and shortly after the onset of acute rheumatism. It recurs with repeated rheumatic cycles.

**Granite Workers' Nasal Resistance in Breathing**—The results of a nasal study that Urban made among 139 granite cutters indicate that the nose may play some part as a protective device in workers exposed to dust hazards. However this part appears to be slight and shows its effect only over long periods

of time. At best it is only one of the factors involved in silicosis. Since the great percentage of the granite workers die of an added tuberculous infection other factors such as personal habits, physical condition and infected contacts are more important than nasal efficiency.

**Urea-Splitting Bacteria and Urinary Calculi**—According to Chute urea-splitting bacteria are frequently found in association with and as the apparent cause of the formation of urinary calculi especially recurrent and multiple calculi. The importance of this fact is not generally recognized. A review of all patients with urinary stone entering the Massachusetts General Hospital during 1937 showed that more than half had an infection with a urea-splitting organism as the only apparent cause. The commonest organism (60 per cent) was the proteus bacillus then nonhemolytic streptococci staphylococci Bacillus pyocyanus Bacillus influenzae and Micrococcus flavus in order of frequency. Of the patients with recurrent stones 80 per cent

were infected with urea-splitting bacteria, and 67 per cent with urea-splitting bacteria had multiple or recurrent stones. Thus, recurrent or multiple stones and such infections go hand in hand. These infections, especially those due to the proteus bacillus are often difficult to cure. They are almost never eradicated permanently until existing stones and also stasis have been removed. Chronicity of infection lessens the chance of permanent cure. The use of ammonium chloride as a urinary acidifier in infections of this type is contraindicated. Sulfanilamide has been the most effective form of drug therapy.

\*Clinical and Hematologic Review of Sprue Based on Study of 150 Cases R. M. Suarez San Juan—p. 137

**Clinical and Hematologic Review of Sprue.**—Suarez believes that an accurate clinical diagnosis of sprue is extremely difficult, if not impossible, without the help of the laboratory. In his series of 150 cases all but two are native Puerto Ricans. There were more males (eighty-two) than females (sixty-eight). One third of the patients were less than 40 years of age. Young children and preadolescents and adolescents are frequently attacked by sprue, a point which might be helpful in distinguishing the disease from true pernicious anemia or Addisonian anemia. The general appearance of a few of the older patients, with premature graying of the hair and the color of the skin, renders them indistinguishable from sufferers from pernicious anemia. The loss of subcutaneous fat and the wrinkling and pigmentation of the skin, more marked on the arms and legs, are some of the few external evidences favoring a diagnosis of sprue. The spleen, frequently enlarged or palpable in Addisonian pernicious anemia, was invariably found to be small or of normal size in the present series. Furthermore, although purpuric or scorbutic spots were occasionally observed on the arms and legs of some of the older patients, in not a single case did the ophthalmoscopic examination reveal retinal hemorrhages. With the exception of one case (a patient whose marrow was probably in a hypoplastic state), in which the mean cell volume was found to be 89 cubic microns, the lowest mean cell volume in the series of 150 cases was 102 cubic microns, the highest 220 and the average for the series 123.6 cubic microns. The color index was found below 1 in twenty-three cases and as low as 0.7 and 0.64 in two cases. The highest color index was 2.2 and the average 1.22. The volume index was never below 1, the highest was 2.3 and the average 1.39. The mean cell hemoglobin varied between 26 and 59 micrograms, with an average of 36.6 micrograms. The lowest mean cell hemoglobin concentration was 20 per cent, the highest 45 and the average for the series 26.1 per cent. The hemoglobin ranged from 16.5 to 102 per cent, averaging 66 per cent, the erythrocytes from 690,000 to 4,410,000 per cubic millimeter with an average figure of 2,710,000. The lowest leukocyte count was 1,550, the highest 13,600 and the average 5,280 leukocytes per cubic millimeter. The author regards sprue as primarily a disease of the hematopoietic system and not of the gastrointestinal tract. Despite its low vitamin B content, concentrated liver extract was found to be highly beneficial in the treatment of sprue, including cases with spinal involvement.

The Principles of Criticism F. Kris and E. Gombrich—p. 319  
The Nescience of the Aranda G. Rohiem—p. 343

**Etiologic Factors of Stammering.**—Laif finds that claims to one universal treatment for all cases of stammering are not justified by actual results and that, whereas some disorders of speech yield to one kind of treatment, quite a large number of cases remain unaffected by it. The author attempts an analysis of a few etiologic factors in the onset and cure of stammering by presenting two simple cases from his clinical investigations. These cases illustrate that the causes of stammering and its treatment vary from one case to another. The first case shows that although stammering may have its inception in those factors (fear of parents, guilt because of masturbation, inferiority, imitation and fear of a stammering heredity) which may be regarded as more or less primary, other conditions, such as lack of steady control over breathing and voice and faulty habits of reading, may further complicate the etiology of the disorder during the course of its development. Consequently, no therapeutic measure can be really effective unless, along with the primary factors it takes into account secondary conditions. Besides the analysis of the second patient's difficulties (which were similar to those of the first patient) in a state of relaxation, the author also tried a few exercises of musical drill with him. In addition to this he was assigned a few tasks requiring delicate handling of instruments in the laboratory in order to help him overcome his sense of inadequacy in manual skill. The period of treatment lasted over eleven months after which the patient was completely cured. Oral or phonetic exercises were not resorted to during the entire course of treatment.

**Weil's Disease.**—During the last two years, Roberton treated four cases of leptospirosis. In addition to these he has had under his care three other possible but unproved cases. The diagnosis should escape no one when jaundice associated with nephritis and nitrogen retention follows an acute febrile illness in which headache, severe muscular pain and scattered hemorrhages have been well marked. In the very earliest stages the clinical picture is suggestive enough to make justifiable the use of serum before the diagnosis can be proved. Sudden onset of a severe illness, with headache (quite frequently meningeal signs), high fever, severe pain, great tenderness in the muscles of the extremities, hemorrhages from the nose and the gastrointestinal and urinary tracts and a most characteristic watery suffusion of the conjunctivae should make it possible for the condition to be suspected. If in the presence of these symptoms and signs there is the history of a possible source of infection to which the patient has recently been subjected, serum treatment should be instituted at once without waiting for the dia-

nosis to be confirmed by laboratory studies. A fuller and wider knowledge of the infection and its manifestations should bring to light other cases. Of the four proved cases of Weil's disease, three occurred as the result of bathing in one river. These three patients (boys) recovered. The fourth patient was infected from the same river, in which he worked.

**Stammering and the Allergic Diathesis**—Kennedy and Williams examined a consecutive series of 100 children who stammered. These children were from 5 to 14 years of age. Of the children examined eighty-one were boys and nineteen girls, eighty-nine proved to be right handed and eleven left handed, and a family history of stammering was present in sixty-five cases and absent in thirty-five. Fifty-two children gave a personal history of allergic manifestations. Migraine plus urticaria and/or asthma was complained of by thirty-two, eleven complained of urticaria alone, in eight there was a history of asthma plus eczema and/or hay fever, and one suffered only from eczema. Thirty of these fifty-two children also gave a history of "fastidiousness" with regard to food generally and dislikes or refusals of particular foods or gastrointestinal upsets after them. Of these fifty-two children with a personal history of allergy forty-eight also had a family history of allergy. In thirty-seven cases one or both parents exhibited allergic manifestations and in six a grandparent was the nearest sufferer. An aunt was the nearest relative in four cases and the allergic symptoms were observed in a sister of the child in one case. Thirty-three of the fifty-two children (including the four with no allergic family history) had a family history of stammering. Seven of the fifty-two children were left handed, six of these seven had a family history of allergy and two also a family history of stammering. In the forty-eight children who gave no personal history of allergic manifestations a family history of allergy was obtained in all except one. Fifteen of these children however, gave a history of "fastidiousness" with regard to food generally and dislikes or refusals of particular foods, or gastrointestinal upsets after them. One or both parents of thirty-seven of these forty-seven children suffered from allergy, a grandparent of five, an aunt of two and a sister of three. Thirty-two of the forty-eight children (including the one with no allergic family history) had a family history of stammering. Four of the forty-eight children were left handed and all had an allergic family history. Three also had a family history of stammering. The close and practically constant association of stammering and allergic manifestations in the personal and family histories of the stammerer, as revealed by the present investigation, rather favors the view that there is something more than a mere casual relationship between stammering and the allergic diathesis.

### Lancet, London

2 1395 1448 (Dec 17) 1938

\*Treatment of Rheumatoid Arthritis with a New Gold Salt S J Hartfall H G Garland and W Goldie—p 1410

**Late Results in Diverticulitis**—Lockhart-Mummery analyzes the late results of 136 cases of the more severe types of diverticulitis. Ninety-one patients were operated on and forty-five were not. The latter were treated with frequent doses of liquid petrolatum to keep the contents of the colon liquid. Many of them had further attacks but when they were careful to adhere to the regimen advised the attacks usually ceased and the patients remained in good health for long periods. Nevertheless, two of them died subsequently from the condition, one from sepsis and the other from a sudden perforation and acute peritonitis. Both patients had refused operation. In all the patients not operated on the diverticula have increased both in size and in number. Small diverticula have become large and fresh diverticula have appeared in previously free areas of the colon. This shows that the weakness of the musculature of the intestinal wall and the tendency to herniation of the mucous membrane once started cannot be arrested. There were fifteen deaths in the entire series directly attributable to diverticulitis. In thirteen

cases the abdomen was opened and after the adhesions between the affected part of the colon and other structures were freed the bowel was wrapped in omentum and sewn into place with fine catgut stitches and displaced into the left side of the false pelvis. The patients were saved a colostomy opening and have remained in good health for from six to fifteen years after operation. Three had occasional attacks of pain and tenderness during the first two years but after that no symptoms at all. One patient so treated developed an endocarditis eight years later but is still alive. Colostomy, usually a transverse colostomy, was performed in thirty-eight cases. Of these patients four died. The remaining thirty-four survived for long periods and have remained free from symptoms. There seems to be no doubt that colostomy is the safest and most satisfactory method of treating bad cases of diverticulitis in which medical treatment will not stop repeated acute attacks or serious complications have occurred or threaten. Twelve patients had perforation into the bladder followed by a vesicocolic fistula. Several were treated by colostomy, followed a year later by resection of the affected colon and closure of the vesical fistula. They did well with the exception of the patient in whom fatal endocarditis developed three years after closure of the colostomy. In seventeen cases resection of the affected portion of intestine with temporary cecostomy or colostomy was performed. Four of these patients died but the remaining thirteen made good recoveries and had no further symptoms referable to diverticulitis. These patients are the only ones that can be considered to have been cured in the proper sense of the word. Exploratory abdominal section was performed in forty-three cases (apart from other operations) with five deaths. Appendicostomy was performed in five cases, in these cases in spite of careful medical treatment and a petrolatum regimen acute attacks of diverticulitis recurred. Appendicostomy proved successful, in all but one the attacks eventually stopped and the patients have remained in good health since. In one case attacks of chronic obstruction recurred and a transverse colostomy was made and the appendicostomy opening was closed. Chronic septic foci elsewhere in the body developed subsequently in fourteen cases, which included seven cases of severe arthritis, four of endocarditis and one each of septic iritis, cerebral abscess and subacute combined degeneration of the cord. This suggests that the original diverticulitis was responsible for the foci, as none of the author's thirteen patients successfully treated by resection developed such foci.

**Fluid Balance in Meniere's Disease**—Cawthorne and Fawcett studied the effect of various salt and fluid intakes on the symptoms of Meniere's disease in eleven cases. All but one were affected to a greater or lesser degree by variations in the intake of fluid and salt. Any steps taken to favor the retention of fluid within the body resulted in an aggravation of the symptoms, whereas the reverse was true when excretion of fluid was encouraged. In nine cases this fluctuation of the symptoms was accompanied by variation in the hearing capacity, thus, when the symptoms were more marked the hearing was worse and vice versa. None of the patients under review tended to retain fluid unduly, although they were all sensitive to variations in the salt and fluid intake. It seems that imperfect functioning of the pressure regulating mechanism of the endolymphatic system places the affected labyrinth under the influence of any factors that may effect the secretion or absorption of endolymph on that side. It is not unreasonable to suppose that an increase of the fluid content of the body may favor an increase of the intralabyrinthine pressure. It is recommended that an antiretentional regimen should form part of the investigation of every patient with Meniere's disease.

**New Gold Salt for Arthritis**—Hartfall and his colleagues used methyl glucamide of aurothiodiglycolic acid the total gold content being 50 per cent, in the treatment of fifty cases of rheumatoid arthritis. The dosage has been approximately half that previously used with other gold preparations but the curative results have been equalled or surpassed. Toxic reactions occurred in a fourth of the patients.

**Effect on Kidney of Hypertension**—Hærner and her associates report studies on the question whether all types of arterial hypertension which persist for a sufficient length of time will necessarily react on the kidneys. They made experiments on dogs. The hypertension by section of the depressors was performed according to the method of C Højmans, that is, at one session and under morphine-ether anesthesia, they resected on each side the internal portion of the vagus nerve (corresponding to the depressor nerve) and the carotid branch. If this operation is carried out correctly and completely, it induces regularly a permanent arterial hypertension. After this intervention the animals were kept under normal conditions of life and their arterial tension was regularly controlled. After from eighteen to twenty-four months had elapsed a time that was judged sufficient for renal symptoms to develop the authors tested the renal function of the dogs. Summarizing the results of these renal tests they say that two years after hypertension had been induced by sectioning of the nerves regulating arterial hypertension the dogs retained a normal renal function. The hypertension of extrarenal origin did not influence the function of the kidney. Contradictory reports about the microscopic aspects of the kidneys in experimental chronic hypertension induced the authors to make microscopic studies. They performed a unilateral nephrectomy extirpating the right kidney in each of the animals. The animals became readily adapted to the unilateral nephrectomy and the microscopic examination of longitudinal and transverse sections of the extirpated kidney showed no lesion that could be attributed to hypertension.

- What Is Disclosed in Profile (Transverse) Poentgenography of Lung P Pruvost—p 223

**Pathogenesis and Treatment of Asthma**—De Bersaques and Berat stress the importance of the constitutional factor in the pathogenesis of asthma and show that an effective therapy of this disorder can be realized only when the complex problem of the asthmatic constitution becomes clarified. By objective and thorough examinations of forty asthmatic patients, they attempted to throw some light on this problem. In the clinical examinations of the asthmatic patients they gave attention to such factors as age, profession, pulse rate, blood pressure and the reflexes. Asthma occurs with equal frequency in the two sexes, but in women the appearance or disappearance of the asthmatic crises is influenced by menstruation, the menopause and pregnancies. They stress the neurovegetative instability, calling attention to the frequency of tachycardia and of exaggerated reflexes in asthmatic patients. Moreover, they show diagrams which indicate that the sphygmolability of asthmatic patients is much greater than that of other persons. In view of the great nervous instability of asthmatic patients, asthma has been designated as a respiratory neurosis. Psychic factors play a part for many asthmatic persons are psychopathic, and psychoanalytic methods effect cure in some cases. Further the authors report their observations on the chemical aspects of the blood and of the urine, on the leukocytic formulas on the basal metabolic tests and on the cutaneous reactions in asthmatic patients. Summarizing their studies on the pathogenesis they emphasize that asthma does not have a single cause but that three factors are of equal importance in the pathogenesis (1) the respiratory factor, (2) the instability of the neurovegetative system and

(3) the hepatic factor. In discussing the therapy of asthma they first take up the treatment. They prefer products containing 0.25 mg of epinephrine and from 0.03 to 0.04 Gm of epinephrine. Thus they avoid as much as possible the brutal and disagreeable vascular reactions and prolong the desired bronchial action. In the treatment during the periods between the attacks they take account of the aforementioned three pathogenic factors. They think that treatment with antiviral vaccine is useful in counteracting the respiratory factor. To modify the neurovegetative instability they recommend sedatives particularly the combination of belladonna, ergotamine and phenobarbital, and sympathicotropic preparations such as ephedrine. To counteract the hepatic disorders they recommend dietetic measures, choleretics and cholecystokinetics and they say that the antitoxic hormone of the liver (discovered by Sato) exerts a favorable action on the evolution of asthma. In the cases in which the existence of an allergen is definitely proved methods of desensitization are indicated. However, the authors think that such cases are rare, because hypersensitivity is the result of a constitutional status in which the liver plays an important part. Except in cases of established anaphylaxis, desensitization should be resorted to only after all other measures have failed.

- Powdered Buttermilk in Treatment of Acute Digestive Disturbances of Nurslings M Pehu and P Woringer—p 270

**Ocular Tests of A Hypovitaminosis in Children**—According to Crussade and his collaborators, the tests employed for the study of A avitaminosis can be classified in two groups: laboratory tests and clinical tests. The clinical methods are based on the ocular disturbances provoked by A avitaminosis. The authors disregard conjunctival or corneal xerosis and keratomalacia, because these disorders appear only in advanced insufficiencies. Of greater interest, because they appear earlier, are (1) the beginning xerosis revealed by the biomicroscope of Gullstrand and (2) beginning hemeralopia. They describe an adaptometer, which was devised by one of them (Thomas). In employing this adaptometer the child is placed in the dark chamber where it has to look at a strongly illuminated screen for two minutes in order to neutralize the influence of the external light. Then the child is left in absolute darkness for thirteen minutes. Following this the child looks at the lighted page of the apparatus. By means of a diaphragm and of filters, the intensity of the illumination of the lettered page is gradually increased. The minimum illumination necessary to recognize the letters indicates the threshold of contrast in the child. To determine the normal threshold, tests were made on fifteen children who were free from hepatic and ocular disorders and who had been treated for fifteen days with vitamin A. To verify the sensitivity of the apparatus, control tests were made on twenty-five other children. Finally the authors employed their method for the detection of a hypovitaminosis on 210 children of school age. The studies were made during the winter. On the basis of their investigations they reach the conclusion that their method meets the requirements of the Hygiene Committee of the League of Nations, that it is easily employed and that it is of great sensitivity. In subjects who are free from hepatic and ocular disorders, it permits the detection of an existing A hypovitaminosis. Its employment in children of school age revealed that latent vitamin A insufficiency is relatively frequent, especially among the poor classes, in which the children receive an inadequate and unbalanced diet. The authors think that it would be interesting to make control tests during the summer when because of the available vegetables and fruits the diet has a higher vitamin A content.

**Nocturnal Enuresis**—Wertheimer first describes observations on the pollakiuria of nurslings. He found that micturitions were most frequent when the nurslings were in dorsal decubitus, somewhat less frequent when they were in the vertical position and least frequent when they were in ventral decubitus. There was on the average one micturition each in thirty eight, fifty three and 104 minutes, respectively, depending on whether the nurslings were in the dorsal, vertical or ventral position. In view of the relatively frequent coincidence between pollakiuria and nocturnal enuresis, the author suggests that nocturnal enuresis is likewise favored by the dorsal decubitus, that is it is justified to suggest a "hyptiogenesis" (hyptios = lying on the back) of nocturnal enuresis. Moreover if pollakiuria can be reduced by ventral decubitus, the same position might be helpful in the treatment of nocturnal enuresis. The author reports the clinical histories of four children ranging in age between 3 and 11. In all of them the nocturnal enuresis was successfully counteracted by the ventral position.

**Vitamins and Ferments in Blood**—Wolf describes studies on the behavior of the vitamin content of the blood in high altitudes. He examined the vitamin content of the blood in healthy persons and patients on the day following their arrival from regions of low altitude and again after a stay of three or more weeks at the high altitude. He found that in the majority of patients with open pulmonary tuberculosis the vitamin A values of the blood were noticeably reduced but that after from three to five weeks in the high mountains a considerable increase could be observed. It is difficult to determine to what extent diet played a part in this increase, but that the high mountain climate as such played an important part is proved by the fact that even in cases in which the appetite was poor and nutrition difficult a considerable increase was observed. In healthy persons the vitamin A values of the blood were likewise higher after several weeks in the high mountains. Studies on the vitamin C content of the blood revealed that of thirty patients with pulmonary tuberculosis only nine had values that were too low, all others had high values the majority even saturation values. These observations contradict those of the investigators who conclude, from a reduced elimination in the urine, that deficiencies exist. The author's observations on the blood do not prove that in pulmonary tuberculosis and perhaps also in other infectious diseases the vitamin C consumption is increased. He suggests that the fever of the infectious process might cause a retention and thus the reduced elimination in the urine would not permit the conclusion that a hypovitaminosis exists. It was found also that the vitamin C values of the blood increase under the influence of the high mountain climate. He detected normal or slightly increased total cholesterol values in many of his tuberculous patients but he noticed a reduction in the cholesterol content of the serum in some of those with acute exudative processes. Like Loewy, he observed that the cholesterol values increased under the influence of the high altitude climate. Finally he gives his attention to the fat-splitting ferments, particularly lipase. On the basis of 250 tests of the lipase content of the serum he concludes that in the majority of cases the lipase values increase in the course of the stay at the high altitude. The height of the lipase titer to a considerable extent parallels the improvement in the pulmonary aspects. It is suggested that the increase in the lipase titer might be the manifestation of the immunity status of the tuberculous organism.

**Trichlorethylene in Allergic Dermatitis**—Ramel discusses the meaning of the term allergy in dermatology and mentions the various manifestations of cutaneous allergy such as urticaria, eczema and parakeratosis psoriasiformis. The latter type of disorder has characteristics of psoriasis as well as of eczema, without being identifiable with either of these dermatoses. As the cutaneous manifestation of an allergic mechanism of microbic nature, parakeratosis psoriasiformis appeared until now as the composite effect of a morbid "antigen-antibody" syndrome in which two elements were necessary but sufficient. Recent investigations, however, demonstrated that this allergic reaction can be subordinated to the specific action of a third element acting in the manner of a catalyzer. The author demonstrates this on the basis of the clinical history of a factory worker who came in contact with trichlorethylene in the course of his work. Renewed contacts with the trichlorethylene elicited new attacks. On the basis of observations made on this patient, the author concludes that the trichlorethylene acts indirectly in the manner of a catalyzer. By means of this catalyzer it is possible to elicit at will an allergic cutaneous reaction the direct and indispensable cause of which appears to be a microbic agent. The microbic agent in the reported case was a hemolytic streptococcus which was obtained from the patches of parakeratosis psoriasiformis reactivated by means of the trichlorethylene test.

\*Action of Vitamins on Hydræmia and Chloridæmia in Nurslings M Pincherle and G Gelli —p 504

**Vitamins for Hydræmia and Chloridæmia in Nurslings**—Pincherle and Gelli made determinations of hydræmia and chloridæmia before and after the administration of vitamins in a group of twenty normal nurslings from 5 to 7 months of age, who were placed in four different groups. Each group was made up of two breast fed infants and three artificially fed with pasteurized cow's milk. Infants in the first and fourth groups had a daily intake of 40 000 international units of vitamin A (first group) and of 0 001 Gm of vitamin D (fourth group) for fifteen successive days. Those in the second and third groups had a daily injection of 0 001 Gm of crystallized B<sub>1</sub> vitamin (second group) and of 500 international units of ascorbic acid (third group) for ten successive days. The amount of water and sodium chloride in the blood was calculated by Bang and Rusniak's methods, respectively. The authors found that before administration of vitamins the amount of water and sodium chloride is normal in the blood of breast fed infants and increased in that of infants who are artificially fed. Vitamins administered have no effect on hydræmia and chloridæmia in breast fed infants whereas they cause diminution of hydræmia and chloridæmia up to normalization of the elements in the blood of infants who are artificially fed. The authors believe that the disturbances of the amount of water and sodium chloride in the blood of infants who are artificially fed are due to a disequilibrium of the endocrine and sympathetic nervous systems from avitaminosis and that both avitaminosis and the endocrine and sympathetic disturbances are controlled by the administration of vitamins.

**The Postoperative Sickness**—According to Paschoud, the principal cause of the disturbances which constitute what Leriche termed 'postoperative sickness' is to be seen in venous stasis. Every surgical intervention through a transient and local influence on the defense mechanisms of the tissues affects three important factors: temperature, pressure and moisture. The lowering of the temperature in the course of the operation affects particularly the local circulation and in a case of

abdominal operations the portal circulation. In the author's experience this cooling process involves even the deeper liver tissues. However, when the operative field is irradiated with infra-red rays at a temperature of 50 C the tissues retain their temperature. Another important postoperative therapeutic measure in prevention of venous stasis and postoperative disturbances is the early postoperative activity of the patient. The infra-red rays are particularly useful in preventing vasomotor disturbances. Another effect of radiation is to be seen in hyperemia, which counteracts pathologic states resulting from venous stasis. Tissues subjected to the influence of inflammation, as in the case of appendicitis, cholecystitis, empyema or peritonitis, are not influenced to the same degree. The infra-red rays here affect only the circulation. The secondary hyperemia, result of the effect of ultraviolet rays, is effective for forty-eight hours after the operation and assures the best local stimulation of vasomotor function.

**Etiology of Megaduodenum**—Weiss reports six cases of megaduodenum in members of the same family in three generations. He considers the incidence of the condition in his cases as a hereditary anomaly. In five of the patients he was able to demonstrate other developmental anomalies of the bowel and the kidneys. His observations support the views of Melchior and Neil to the effect that congenital cases of megaduodenum remain symptom free for many years and exhibit first symptoms under the influence of some unknown cause. Megaduodenum is frequently overlooked, many of the cases are treated for other illnesses, while in still others the condition is discovered in the course of an operation. In the presence of mild disturbances of peristalsis the condition may be treated conservatively. Formidable manifestations require operative intervention. The condition is not improved by a gastro-enterostomy, the second Billroth operation with termino-lateral gastro-enterostomy or a duodenojejunostomy. The best results, according to the author, are to be obtained by the second Billroth procedure with  $\gamma$ -anastomosis after Roux. The author is of the opinion that a careful investigation of the family history in every case of megaduodenum would reveal hereditary characteristics.

Field Fever in Rural Practice W Lohmuller Jr—p 1993

**Field Fever**—Joerdens reports his observations on eighteen patients with field fever, a spirochetosis, which in previous reports has been designated also as "harvest" fever. Sixteen of the patients had done harvest work but only a few had worked in damp fields and meadows. One patient, a soldier, developed field fever twelve days after return from a furlough, during which he had assisted in harvesting. Another patient, a baker, had not done harvest work, but he had been bathing in a river of the region in which cases of field fever had occurred. The patients suddenly developed high fever, usually with chills, they complained of severe headaches, sensations of dizziness and pains in the limbs. Nearly all the patients were stuporous during the first few days and many had attacks of vomiting, abdominal pains and diarrhea. A characteristic sign at the onset of the disease is a conjunctivitis of varying severity. The blood pressure was low and this hypotension persisted in some of the patients after the discharge from the hospital. During convalescence, bradycardia was frequently observed. In two patients an exanthem resembling that of measles appeared, but it subsided again in the course of forty-eight hours. Serologic examinations of the blood proved positive in all cases. In one case *Leptospira* was cultured from the blood on the second day of the disease. All the patients recovered in the course of two or

three weeks. Six of them were treated with a field fever (rabbit) serum. Three patients were given one intramuscular injection of 10 cc each, in the other three the serum injection was repeated after two or three days. On the basis of his favorable experiences with the field fever serum the author recommends its use, particularly during the early period of the disease. He points out that Rimpau regards field fever as a nonicteric form of Weil's disease. Both disorders are spirochetal fevers and their clinical course is similar.

Three New Roentgenographic Methods That Are Important for Neurology B G Ziesdes des Plantes—p 619

Disappearance of Genuine Epilepsy After Epidemic Encephalitis A Werner—p 623

**Insulin Shock and the Eye**—Schmidt says that, since insulin has been introduced into the treatment of schizophrenia, numerous reports have appeared about changes that develop in different organs. Even ocular disturbances, particularly pupillary disorders, have been observed and so the author was induced to make studies on the eyes of schizophrenic patients during insulin shock therapy. His investigations were made on ninety-one patients in the course of 658 attacks of shock. To describe the behavior of the eye under insulin action the more clearly, he differentiates four stages. The first stage extends over the period from the introduction of the insulin to the onset of shock. The second stage is the period of shock which begins, according to the author's opinion, when the patient fails to respond to calling and pinching. The third stage is the period of deep shock during which all reflexes are abolished. The fourth stage covers the period from the administration of sugar to complete awakening. Summarizing his observations on the ocular changes during the various phases of insulin shock, the author says that all patients showed a loss of tonus of the external eye muscles during the third stage, impairment of the sensitivity of the conjunctiva and cornea during the second, the third and the beginning of the fourth stage, and pupillary changes during all four stages. In some of the patients there appeared during the first three stages peculiar positions of the eyes, during the first stage a horizontal nystagmus and during the second, third and fourth stages a hyperemia of the retina and of the choroid. The intra ocular pressure, the refraction, the oculocardiac reflex and the pressure of the retinal vessels showed no deviation from the normal. The reported changes prove that the eyes participate in the processes elicited in the organism by insulin shock. It is noteworthy that the manifestations on the visual organ are not uniform and that an alteration of the sympathetic equilibrium in a certain direction is not observable. None of the patients showed ocular changes traceable to the effect of insulin after the shock therapy was completed.

**Immunity Against Anthrax**—Ivanovics cites experiments by other investigators which proved that the capsule of anthrax bacilli has antigenic characteristics which differ from those of the body of the bacilli. It was demonstrated that the protective action of the serum was dependent entirely on its content in antibodies from the capsule and that the antibodies from the soma were of no importance in this respect. After reviewing immunization experiments with the R variant of the anthrax bacilli by Bail, the Stamatis and Sterne, Ivanovics describes

his own studies on the mechanism of anthrax immunity. He shows that the immunity of rabbits vaccinated with sterilized edema fluid has no connection with the antibody of the capsule. The capsule antibody could not be demonstrated in the blood of the animals so immunized nor was it possible to counteract the immunity of the animals with purified capsule antibody. Mice that were vaccinated with 1 cc of serum from an immunized rabbit showed hardly greater resistance against anthrax infection than the untreated controls. Rabbits can be successfully immunized with the noncapsulated R variant of the anthrax bacillus. The edema fluid from a guinea pig that has died after infection with the R variant likewise effects immunization in rabbits, in this edema fluid even the highly sensitive serologic examination fails to demonstrate the specific substance of the capsule of the anthrax bacillus. Mice could be immunized neither with edema fluid nor with large quantities of killed capsulated anthrax bacilli.

Clinical Differentiation of Cases with Incipient Renal Tuberculosis from Cases with Nonspecific Papillitis Necroticans H. Schneider—p 777

\*Operation for Coral Calculus K. Heusch—p 800

Hemorrhages from Kidneys Congested as Result of Constricting Vessels H. Schneider—p 804

**Operation for Coral Calculus**—Heusch believes that pyelotomy is preferable to nephrotomy but admits that in some instances, such as in cases of a parenchymal calculus or of a fixed coral calculus, an incision into the renal parenchyma cannot always be avoided. However, it is gratifying when even in these conditions pyelotomy can be done instead of nephrotomy. This applies even to calculi that are shaped like antlers. If the anatomic conditions favor a pyelotomy, neither the size nor the extensive ramifications of the coral calculus are a contraindication to pyelotomy. The conditions which favor pyelotomy in the presence of a large anchored coral calculus are (1) good mobility of the pedicled kidney and (2) considerable size and width of the extrarenal portion of the pelvis of the kidney. Under these conditions the technical measures consist in breaking up the easily accessible coral calculus and then removing the fragments. The author reports the clinical history of a woman, aged 43, in whom a large coral calculus was removed by pyelotomy. The kidney was exposed by a slanting incision into the flank. It was moderately adherent to the surroundings, but it was easily pedicled and lifted out. After the kidney had thus been exposed its pelvis was visible and this was opened by a long pyelotomy. After the pyelotomy opening had been spread apart by holding threads, the conical end portion of the coral could be extracted. An attempt to remove the remaining portions of the coral by means of the thumb and forefinger failed and so the calculus was crushed into several pieces and these were removed by means of forceps. The removal was controlled by the palpating finger. A thorough irrigation concluded the cleansing of the renal pelvis. A transrenal fistula was made and after the patency of the ureter had been tested the renal pelvis was sutured. The postoperative course was uneventful. The fistula closed quickly. An examination several months later proved that the patient was free from complaints and that the function of the kidney was excellent.

Tuberculosis in Malarial Patients Ya. M. Kaziev—p 60

**Tuberculosis in Malarial Patients**—According to Kaziev there exist in the literature two opposing views with regard to the antagonism of tuberculosis and malaria. A number of authors, including Schoenlein, Mutzner and Shirokogorov, point to the rarity of tuberculous lesions in malarial patients. Another

group of authors maintains the opposite, i. e. that malaria aggravates the course of the tuberculous infection. Among the 5,580 patients admitted to the tuberculosis dispensary of the region of Baku, where malaria is endemic, there were 342 malarial patients with pulmonary tuberculosis in various stages. The author studied the incidence of malaria in a group of 1,212 patients with open pulmonary tuberculosis. There were 338 (27 per cent) who likewise had malaria. Thirty-three had recently acquired malaria, forty contracted malaria in the past six months and forty-four within one year, while 254 (75.1 per cent) had malaria for more than one year. By careful study of their histories it was possible to ascertain that in 165 (48.8 per cent) malaria preceded tuberculosis, while in 173 (51.2 per cent) malaria was acquired after pulmonary tuberculosis. The similarity in the symptoms of the two diseases may lead to diagnostic errors. However, the diagnosis of malaria can be established on the history of typical malarial attacks which yielded to specific treatment. Fifty-seven per cent of the tuberculous patients presented a fibrous or fibrous productive form of pulmonary tuberculosis, while cavities were present in 60 per cent. The remaining 43 per cent included severe pneumonic, infiltrative and other forms of pulmonary tuberculosis. Observations of this group over a period of five years revealed progression of the tuberculous process in 112 (33.1 per cent), marked aggravation in twenty-two (6.6 per cent), a stationary course in forty-eight (14.2 per cent), improvement and arrest in 135 (39.9 per cent) and a complete arrest in twenty-one (6.2 per cent). A study of histories of 369 patients dying of pulmonary tuberculosis in 1934 and of fifty-eight dying in 1935 revealed that 17 per cent were also afflicted with malaria. In order to throw light on the course of tuberculosis developing in patients who had had malaria for a long time the author studied a group of 338 open cases of pulmonary tuberculosis. In 165 of these, malaria preceded tuberculosis by from three to five years. Sixty-four and two-tenths per cent of these presented a mild course with predominance of fibrosis. It appeared therefore that the course of pulmonary tuberculosis in old malarial patients runs a milder course. However, in 21.1 per cent of the cases there was a progression of the disease. In the reverse instance, that is, when a tuberculous patient develops malaria, the tuberculous process becomes aggravated. A study of such a group of 173 patients demonstrated that 57.2 per cent of these showed progression and 13.3 per cent remained stationary, while 29.5 per cent improved. On the basis of his observations the author cannot support the theory of antagonism between the two infections since more than one half of the cases in which two infections coexisted showed an aggravation of the tuberculous process.

**Determination of Hemoglobin in Undiluted Blood**—Hesse says that Philipsen suggested to him in 1935 that the hemoglobin could be determined in the undiluted blood by hemolyzing the specimen with saponin and simultaneously reducing it with sodium thiosulfate and then placing it into a wedge chamber of capillary height, the wedge of blood color can thus be compared with a standard color. On the basis of this suggestion a hemometer was developed and the exactness of the new method was tested in the laboratory in Copenhagen. The author describes and illustrates the capillary wedge hemometer. He shows that since the quantity of the blood specimen does not

have to be determined, the mouth pipet can be replaced by a hand pipet. By exerting pressure with the finger on the rubber rim, the first drop of blood can be drawn up and more blood flows after, until the anterior chamber is filled. The reagent, which is added, is a powder consisting of a mixture of saponin, sodium thiosulfate and sodium oxalate. By this addition the blood specimen is hemolyzed, reduced and stabilized. By experiments it was demonstrated that within certain limits the quantity of the powder is without influence on the results and for this reason exact measurement of the powder is unnecessary. As soon as the specimen is clear, the capillary chamber is filled, that is, by capillary attraction the blood runs under the wedge piece and the color can be compared at once. In a historical review the author shows that the principle of the capillary chamber was suggested at about the turn of the century but for technical reasons was not perfected. After describing the technical measures that were necessary to insure exact results, the author reviews comparative tests which revealed that the new wedge chamber hemometer for undiluted blood meets all clinical and many scientific requirements.

**Elimination of Cholic Acids in Healthy Animals.**—Josephson and his associates show that, although the elimination of bile acids after oral as well as after intravenous administration has been studied by several investigators some important aspects of this problem still remain unsolved. They decided to study the cholic acid content in blood and bile and to observe the correlation between the blood content and the secreted amounts. They wanted to determine the elimination rate for cholic acid in blood and bile in healthy cats and rabbits, since they intended to use these animals for investigations of the cholic acid elimination under pathologic circumstances. They also made an attempt to determine to what degree an injected amount of unconjugated bile salts could be conjugated in the organism. Further they compared the effects of the injection of cholic acid into a peripheral vein and into a vein of the portal system. Finally they studied the ways in which the bile acids are eliminated from the blood. The experiments revealed that, although absorption is effected for the greatest part in the liver, the walls of the blood vessels also play an important part in the absorption of the bile acids for the results obtained in animals in which the hepatic vessels had been ligated can be explained in no other way. The results after the injection into the portal vein are more difficult to explain. After this type of injection the liver cells suddenly are offered blood, which is a rather concentrated bile salt solution. The most probable explanation of the obviously delayed absorption of bile salts after injection of large doses into the portal vein seems to be either that the liver cells were intoxicated by this overwhelming bile salt supply or that their excreting ability was at once exhausted. In this manner they may become immobilized and the animals may behave like those in which the liver vessels are ligated. This explanation is supported by the fact that when small doses are injected intraportally the reaction was the same as after peripheral injection. Experiments with animals treated with india ink and thorium dioxide solution indicate that the delayed excretion after intraportal injection of large doses probably cannot be explained by a blockade of the reticulo-endothelial cells, since animals so treated reacted normally. The fact that the cholic acid content increases also in peripheral blood during the resorption of great amounts of bile salts from the intestine may have the same cause as the delayed absorption after injection into the portal vein. Bile acids given orally in large amounts, to obtain an abundant flow of bile, may have an effect quite the opposite to that desired if the supply has been too ample. If they are injected intravenously no risk of that type seems to exist. Discussing the observation that during the initial period of about thirty minutes after the injection of sodium cholate the bile acids are excreted in unconjugated form, the authors say that gradually more and more of the excreted acids were conjugated even when their concentration in the bile still was far above the normal. This demonstrates that the conjugation of the bile acids by the formation of their peptide linkage is a time-consuming process and therefore probably of enzymatic character. After citing observations by several other investigators the authors suggest that enzymatic powers may be the cause as well of the peptide synthesis as of the normally occurring synthesis of conjugated bile acids. The

reported experiments have shown that unconjugated bile acid, when rapidly excreted, may escape from this enzymatic power.

**Elimination of Cholic Acids in Experimental Jaundice.**—In this report the same investigators (Jungner, Rydin and Josephson) report their studies on the elimination rate when the tissues are more or less loaded with bile salts. They observed the elimination in previously jaundiced animals, in which they also had ligated the afferent liver vessels before the injection of the bile salt. In the summary they say that the elevation of the bile acids in the blood in obstructive jaundice found by other authors in dogs was confirmed in rabbits and cats. The fact that this elevation appears later in cats than in rabbits was explained by the different elasticity of the bile ducts of these two species. The authors also confirmed the observation of other investigators that the augmentation of the bile salts after cholate injections is much greater in these than in normal animals and that the elimination is greatly delayed. The elimination rate follows a typical curve. An approximate calculation of the total amount of cholates in the blood of the animals four minutes after the injection, however, shows that even in obstructive jaundice a considerable part of the supplied salt disappears from the blood immediately after the injection. In this short time scarcely any urine was formed and an excretion of bile salts through the kidneys could not have taken place. In the preceding paper they demonstrated that the rapid disappearance of cholates in healthy animals could depend not only on fixation in the liver but also on a surface adsorption on the walls of the blood vessels. In the animals with obstructive jaundice this surface adsorption did not take place, which was demonstrated by experiments on cats with both obstructive jaundice and excluded liver circulation. In these experiments the cholate quantity remaining in the blood was about the same as the injected quantity. It seems that the tissues and the walls of the blood vessels were saturated with bile salts. Compared with the experiments on animals with obstructive jaundice and maintained liver circulation, these animals demonstrated the capacity of the liver to fix bile acids even in severe jaundice. The cholic acid content of the blood of animals with toxic hepatitis caused by phosphorus and by carbon tetrachloride was found to be definitely higher than normal but not of the same magnitude as in obstructive jaundice. The elimination curve of injected cholic acids was different from the normal elimination as well as from that of the animals with obstructive jaundice. The first augmentation of cholic acid in the blood after injection was of normal magnitude but the subsequent decrease was delayed. The delay found in the excretion agreed fairly well with the results of the microscopic examinations. This indicates that in hepatitis of this type the tissues still have the ability to absorb the bile salts but that their excretion is diminished as a result of the injury to the hepatic parenchyma. Altogether it seemed that the cholate concentration of the blood after the injections was much more in correspondence with the condition of the liver than was the concentration before the injection. The values found after injection of small doses corresponded fairly well to those after large ones. For these reasons the authors believe that analysis of the cholate concentration in the blood of patients after injections of sodium cholate can serve as a functional test of the liver.

## PROSTATECTOMY OR TRANSURETHRAL PROSTATIC RESECTION?

A PLEA FOR THE SELECTIONIST

EDWIN DAVIS, M.D.  
OMAHA

Be not the first by whom the new are tried,  
Nor yet the last to lay the old aside  
—Pope

It is obvious that a literal interpretation of Pope's doctrine of conservatism universally applied would be a complete and effectual bar to all progress. Yet most persons would do well to plod the ultraconservative path, leaving the trial of the new to the gifted and venturesome few.

Overenthusiasm inevitably follows the discovery of a new therapeutic agent, particularly that discovery which tends to be startling or which carries with it a dramatic appeal. After overenthusiasm, in varying degree but in definite sequence, come publicity, commercial exploitation, incompetence and abuse, followed by poor results, recognition of defects and dangers, fear, decreased use and overcorrection, until, finally, such merits as may exist become recognized in their true light and the new therapeutic agent (drug or surgical method) reaches stability at its proper level of usefulness (chart 1). This process of trial and evaluation may require months or years. The pernicious practice of blood-letting persisted through the centuries. The changing attitude of the profession toward nephropexy a generation ago afforded a classic example of this cycle, with the exception that the vicious commercial exploitation feature was lacking, in that there were no kidney hammocks on the market. Mercurochrome, mandelic acid and fever therapy, each has had its fling and each its appraisal. A host of other remedies might be cited. The most recent conspicuous example is the magic medicine sulfanilamide, certainly a drug of most unusual merit, although falling somewhat short of enabling the internist to dispense with history taking and physical examination and seeming to be now on the downgrade.

The opinions and ideas concerning transurethral prostatic resection here presented, although based to some extent on personal experience and on the literature, are derived almost wholly from an impartial analysis of opinions contained in personal communications received from 100 American urologists of recog-

nized ability and integrity, arbitrarily and impartially chosen. Letters of inquiry written in an attempt to sense the present trend of opinion were sent during February 1938 to the fellows and active members of the American Association of Genito-Urinary Surgeons and to every tenth name included in the alphabetical roster of diplomates of the American Board of Urology. The list consisted of men of reputation and accomplishment, most of them well known through their writings and all of them competent and without cause for prejudice, although it happened to include those names which have been most conspicuously identified with the development and the popularizing of the transurethral method. I refer particularly to Caulk, T. M. Davis, McCarthy, Alcock and Bumpus. The inquiry was not a questionnaire as such but rather in the nature of a personal communication requesting an opinion. Those solicited were most generous and courteous in response, more than 95 per cent replying. This report consists of a summary and digest of, as well as interwoven quotations from, the first hundred replies received, after duplicate opinions from those associated in the same office or clinic were excluded.

### DIVERGENT VIEWS

By far the most striking impression which one receives as a result of reading these hundred letters is one of amazement that there should be such wide discrepancy in opinion. The transurethral method is extolled to the skies and condemned utterly. There are the extremists and the nihilists. There are those resectionists who recognize no contraindications and no limitations so far as the size of the gland is concerned, and there are those who refer to the transurethral method as "whittling" or "electrocution" and who will have none of it. Writing on this subject in the *British Medical Journal*, Walker<sup>1</sup> states that "in England, perhaps owing to our happy genius for discovering middle courses, these extremes of opinion are seldom encountered."

### CLASSIFICATION

An accurate classification of urologists based on technic employed is as impossible as it is purposeless. Nevertheless it is quite possible to draw certain general conclusions, based on table 1, showing three general groups of urologists, two of which are small minorities: (1) resection extremists, (2) prostatectomy extremists and (3) a large middle group made up of "selectionists." As indicated, there is some overlapping of groups, since even surgeons performing either a very large or a very small percentage of resections are necessarily also selectionists.

Owing to lack of space, this article is abbreviated here. The complete article appears in the author's reprints.

Read before the Section on Urology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

<sup>1</sup> Walker, K. M. Transurethral Resection of the Prostate. *Brit. M. J.* 1:901 (May) 1937.

*Panresectionists* — Included among the resection extremists, who employ this method in at least 90 per cent of cases, there is a small minority, totaling eight, designated panresectionists, who recognize no limitations with respect to the size or shape of the prostate and who perform prostatectomy only on very rare occasions for some mechanical lesion, such as urethral stenosis or ankylosis of the hip, or for the purpose of demonstration to students. Kretschmer<sup>3</sup> has "taken the prostates as they came, big little, hard and soft" and has "refused no patient relief from prostatic obstruction by the transurethral route, irrespective of age or physical condition." Others feel that size in itself is no contraindication. Alcock<sup>4</sup> believes that "the size of the gland has little if anything to do with the indication for prostatic resection" and even states that a large prostate is "easier (for him) than the small." For several years Sisk<sup>5</sup> has "used transurethral resection in almost 100 per cent of cases." Bunpus's<sup>6</sup> statement that "the first year we operated in all the county cases by resection just to prove that it was possible" suggests that perhaps the resectionist views the large prostate as a challenge to his ingenuity and skill. Another example of how far

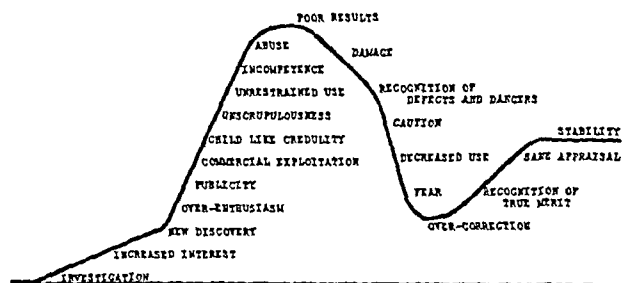

Chart 1—Trial and appraisal, the reaction of the medical profession toward anything new

one may be carried by his enthusiasm is afforded by Thompson's<sup>4</sup> suggestion for prostatic resection through a perineal incision in cases of difficult urethral instrumentation, causing one to wonder why the contraindication to complete clean enucleation of the gland through the existing incision

*Nihilists*—"The number of operations that should be handled with the resectoscope should be somewhere in the neighborhood of one hundredth of one per cent, or less." The point of view of this outspoken nihilist is shared by a small minority, although the entire group (numbering twenty-two) who limit their transurethral activities to "those conditions for which the punch operation was formerly indicated" are essentially nihilists so far as the cutting loop, as applied to benign hypertrophy, is concerned.

*Selectionists*—"Transurethral resection is the ideal method of dealing with obstructions which, by their nature, are unsuitable for enucleation." This concise and expressive statement by G. G. Smith<sup>5</sup> represents the opinion of many. Comments concerning the advisability of selection make up by far the most interesting and instructive material contained in the letters. Well over eighty letters expressing volunteer opinions on this phase of the subject are practically unanimous in favor of selection, although some only to a limited extent. Discrimination is evident among ardent resec-

tionists such as Nesbit and Hamer,<sup>3</sup> the latter of whom feels "that some conditions are more satisfactorily cured with more safety and less time by open operation than by repeated resections." "Obstructing prostatism merits discriminating allocation of method to case rather than case to method" (McCarthy<sup>2</sup>). "I am still selecting my cases for both methods of procedure" (Thomas<sup>4</sup>). Livermore,<sup>6</sup> who believes resection to be "the greatest advance in prostatic surgery since Hugh Young's monumental work," states that it is "not applicable in all cases" and suggests "a happy medium." Indicating his open-mindedness, Osgood<sup>3</sup> is "delighted to use the transurethral method for bars, vesical outlet constrictions and small median lobes," while Rathbun<sup>3</sup> considers resection to be "a very valuable procedure which has been considerably overdone." Chetwood,<sup>7</sup> summarizing over twenty-seven thousand cases of transurethral resection through questionnaire replies, concludes that "caution as well as restraint should be exercised" in transurethral operations, which "should be applied in a selective group of cases." Schmidt<sup>3</sup> believes that "many patients are best operated on by open prostatectomy." Since a number of these quotations are from ardent resectionists, further enumeration of the many opinions of this kind would seem to be unnecessary. It is important to note Walker's<sup>1</sup> statement that the majority of British urologists employ resection "in moderation."

Yet "selection" does not tell the entire story. As Alcock<sup>8</sup> mentions, there are certain well known operators who have devoted themselves almost exclusively to transurethral resection, perineal prostatectomy or suprapubic prostatectomy (for instance, Alcock, Young and Hunt) and have obtained conspicuously good results. Since this "certainly is not fitting the operation to the patient," it is obvious that a skilful and practiced few have succeeded in fitting the patient to the surgeon.

#### TREND

It is significant that of forty-one urologists making specific statements as to trend or tendency in their own work, eight (20 per cent) say that transurethral operations are showing an increase while with thirty three (80 per cent) the trend is toward a decrease. Included in the latter group are a number of formerly high percentage resectionists of wide experience. On the other hand, included in the former group are certain New Englanders of recognized conservatism, while Bugbee,<sup>3</sup> "with accumulated experience," has become "more and more enthusiastic." Another surgeon notes that his "enthusiasm is waning." Culver<sup>3</sup> has submitted accurate yearly figures, beginning in 1932, "with resections increasing from 70 per cent to a peak of 90 per cent in 1934 and then tapering off to 60 per cent in 1937."

#### PUBLIC DEMAND

"My impression is that the public is undergoing a change in opinion" (Hepler<sup>3</sup>). "Insistent demand for 'the needle treatment,' 'the electric method' and relief 'without cutting,' by patients, relatives and physicians, created by premature publicity and commercial exploitation and based on the original misconception that resec-

tion is a simple office procedure, without incision and without risk, has had its injurious effect. In this connection, credit should be given Lewis and Carroll,<sup>9</sup> who in 1933, "in the midst of the wild stampede in favor of resection," recognized the limitations and the dangers in connection with this procedure and had the courage to present an outspoken analysis advocating conservatism and caution. They said "It is not only erroneous but dangerously misleading to teach that prostatic resection is minor surgery." This public clamor and increased "prostate consciousness" have been fostered and developed not only by resection propaganda but also by misinformation given wide publicity in syndicated newspaper medical columns, by pernicious faker radio advertisements, and by silly and purposeless feature articles in popular magazines. For instance, under the title "No Cause for Alarm," Maxine Davis in the *Pictorial Review* for January 1938 devoted several columns to startling and lurid misinformation concerning the prostate gland, in an article well calculated to be the occasion for worry by the uninformed and to cause the intelligent reader to wonder how it happens that this author knows something of serious and dire consequence with respect to the prostate gland of which urologists who have devoted their lives to the study of this subject are not aware.

It seems, however, that the same urgent demand no longer exists, and that "the wave of propaganda in favor of resection which has swept the country" (G. G. Smith<sup>5</sup>) is tending to recede. In Shupe's<sup>3</sup> opinion, resection "has run its course, as far as its appeal to the public is concerned" and "patients do not request it any more." Geisinger<sup>3</sup> feels that "patients are now much less assertive" whereas "some time ago they were demanding resections with great unanimity." This author adds "I contributed my part to this overenthusiasm." Patch<sup>3</sup> thinks "that a saner outlook is being regained," and Bransford Lewis,<sup>3</sup> of "Moonlight and Roses" fame, makes the positive statement "We insist on making our own selection of method to the exclusion of the opinion of any one else concerned." "Less public enthusiasm" has been noted by Howze.<sup>3</sup> He says "This presumably is due to the fact that the patients do a great deal of talking among themselves and must tell each other of unsatisfactory results." Finally, selectionists now occasionally witness the spectacle of the patient who himself demands prostatectomy in order to "Have it over with." It therefore seems definitely established that "the stampede has run its course" and that the demand pendulum is swinging back.

#### TIME AND COST

"The question of hospital cost must be weighed against the possibility of recurrent hospitalization" (Randall<sup>3</sup>). It is the prevalent and accepted opinion among physicians and patients that the transurethral method materially lessens the period in the hospital and hence the cost. In view of the fact that herein lies the chief selling point, it is surprising to note that opinion on this phase of the question is by no means unanimous. Many dissenting voices arise, basing their contradiction chiefly on the "prolonged and trying period of convalescence after leaving the hospital" and the obvious fact that the necessity for multiple sittings unquestionably nullifies resection's chief advantage. For instance Green<sup>3</sup> says "The actual convalescence,

even though it is not in the hospital, is longer." Deming<sup>3</sup> believes that "by Hinman's<sup>11</sup> technic," including plastic closure of the prostatic capsule and the perineal incision, following perineal prostatectomy, "a large adenoma may be removed and a healed wound with normal urine obtained in a shorter time than with the transurethral method." "I still think that perineal prostatectomy gets the patient through the operation in just as short a time and with a much better functional result" (G. G. Smith<sup>3</sup>). As ardent and able a resectionist as Bumpus<sup>3</sup> concedes that "suprapubic prostatectomy makes a shorter stay in the hospital than multiple transurethral resections." The suggestion that a shorter period in the hospital, with a lower hospital bill, conserves the patient's funds with which to pay the surgeon hardly seems to have a proper place in a clinical discussion. Postresection complications, such as delayed hemorrhage and persistent residual urine, requiring repetition, necessarily tend to prolong the stay in the hospital and thus to minimize the chief advantage of resection. Making specific reference to the time consumed in the hospital, Turner<sup>12</sup> reported a series of 100 resections with an average

period in the hospital of thirty-five and one-half days. It is therefore evident that there are two sides to the time question and that the period associated with resection may not be the shorter when measured by duration of symptoms and, sometimes, even when measured by the time in the hospital.

#### ABUSE

"Unfortunately, like other procedures which have been rather extensively exploited, transurethral resection has fallen into the hands of incompetent and unscrupulous persons, who have caused a good deal of damage and discredit to what can be a good procedure. I think this is one of the great advances in the treatment of prostatic obstruction" (Lower<sup>3</sup>). Keyes and Ferguson<sup>13</sup> state that one dealer "has sold more (resection) instruments than there are urologists in the United States." Abuse includes (1) the employment of the resectoscope by those not properly qualified and (2) the performance of unnecessary operations, either because of poor judgment or for other reasons. "Untrained operators are doing too many financial operations" and "I sincerely believe that a great many people are being unnecessarily operated on, the chief reason being one that I hate to mention" are typical comments from well known urologists. "The procedure is being used for chronic prostatitis and other conditions which do not require any operative pro-

cedure” “I think that almost every one who has had the slightest symptoms arising from prostatic hypertrophy has been resected” “The introduction of the resectoscope has been responsible for the performance of thousands of unnecessary operations” In fairness, however, it should be pointed out that these typical criticisms, from men of national reputation, apply not to the method but rather to certain human traits The obvious and inevitable consequences of abuse are unnecessary deaths, unnecessary suffering, unnecessary expense and undeserved discredit to a very useful procedure

SKILL AND EXPERIENCE

All urologists agree that resection, aptly referred to by Hess<sup>3</sup> as “a specialty within a specialty,” is an undertaking for the expert In fact, majority opinion considers this method to be more difficult and complicated than suprapubic prostatectomy, as to both technical execution and after-care Twenty-one letters refer to this phase of the subject, most of them suggesting that “the attitude of the surgeon toward resection, as well as his mortality rate and end results, bears a direct relationship to his skill and experience” This is too obvious to require discussion Braasch<sup>3</sup> has observed that “the proportion of transurethral resections and prostatectomies done by the urologist varies directly with his ability and experience in this field”

TABLE 2—Comparative Mortality Rates (Davis)

	Total Consecutive Cases	Series Without a Death	Deaths	Mortality Rate
Perineal prostatectomy	741	121	20	2.7%
Transurethral resection	361	107	21	5.8%

Stevens<sup>3</sup> feels “very strongly that there is little done in the field of surgery which has so large a personal factor” and adds that “urologists inadequately trained in surgery will naturally pull hard for the transurethral method, although this by no means implies that all urologists favoring resection are poor surgeons” Bugbee<sup>3</sup> believes that “one should do several hundred resections before one is in any way able to master the technic,” and, confirming this statement, it is a matter of common knowledge that operators who have performed a large series of resections have reported a high initial mortality rate, later conspicuously lowered Obviously, transurethral resection cannot be learned through an apprenticeship or by observation As G G Smith<sup>6</sup> has stated, “Proficiency can be attained only through individual experience” Keyes and Ferguson, recognizing the value of resection, particularly for prostatic sclerosis, refer to the “yeoman resectionists” and to “the ease with which some do and others pretend to do this operation”

MORTALITY RATE

Obviously the mortality rate of transurethral operations varies in inverse ratio with the skill and experience of the surgeon and unquestionably may be made exceedingly low Summarizing mortality reports, Bumpus<sup>15</sup> concludes “It is evident that in the hands of the experienced the mortality should be less than 2 per cent,” whereas McCarthy<sup>2</sup> feels that “the mortality in competent hands should vary from 1 to 4 per cent” In Lower’s<sup>3</sup> opinion, “The greatest advantage of transurethral resection is that it carries a much lower

mortality” Barringer performs 60 to 70 per cent of resections because the “mortality is so much reduced,” in spite of the fact that “all in all the operation is not quite as effectual as prostatectomy” Many others comment on the conspicuously low risk of resection as compared with suprapubic prostatectomy In fact, this is generally accepted, although a discordant note is introduced by such statements as “the low mortality from resection in the hands of the average operator is due to the fact that many of his patients should never have been operated on” It seems very doubtful, however that the “average” resectionist actually has a low mortality rate Negley,<sup>16</sup> analyzing 400 operations on the prostate, half by each method, performed by various general surgeons and urologists in two large hospitals, one charity and the other private, found that the deaths following resection outnumbered those following prostatectomy three to one

A number of operators who use the perineal approach have reported mortality figures distinctly better than their own resection figures and comparing favorably with the figures reported by recognized resection experts My own opinion is in accord with that of McCarthy,<sup>2</sup> who believes that “the mortality of resection in skilled hands, while lower than suprapubic mortality, approximates that of perineal prostatectomy” Cecil<sup>3</sup> does not believe that resection “compares with perineal prostatectomy as to mortality” G G Smith,<sup>6</sup> who likewise has a lower prostatectomy mortality rate, considers that the resection mortality rate in the hands of the “great majority” is “perhaps 10 per cent” and adds that “hundreds of patients are being sacrificed every year by men who are endeavoring to learn the technic of transurethral resection” According to Randall,<sup>3</sup> “the resection mortality is certainly 10 per cent, probably higher” My own mortality rate for perineal prostatectomy, as indicated in table 2, is 2.7 per cent, as compared with a 5.8 per cent resection rate for a series combined with that of my colleague Owens

FUNCTIONAL RESULTS

“The patients seemed happy that they were able to void” and “were mostly satisfied with the result, indeed much better satisfied than I” This honest and delightfully concise expression by MacKenzie<sup>3</sup> of Montreal comes very near to telling the entire story Beer<sup>1</sup> is “impressed by the reports of large numbers of ‘resected’ patients who require continued treatment” and has “no doubt that most resected cases void more readily and have much less residual than prior to operation, but large numbers are not absolutely and definitely cured, as they are after a complete enucleation,” and “pyuria, frequency and dysuria often persist for months or permanently”

Of the hundred letters, fifty-five contain volunteer opinions with respect to the all-important question of the ultimate success of the operation as measured by the completeness and permanence of symptomatic relief Of these, sixteen (30 per cent) express satisfaction with the end result, although in a number of instances this opinion is qualified by such expressions as “if properly done” or “in properly selected cases” “I should say that the results are just as permanent and complete” is the opinion of Caulk,<sup>3</sup> while Crowell<sup>3</sup> believes “that the permanent results are just about as good”

15 Bumpus H C Present Status of Transurethral Resection of the Prostate J A M A 107 494 (Aug 15) 1936

16 Negley J C in discussion on Bumpus and Massey<sup>15</sup>  
17 Beer Edwin in discussion on Kretschmer<sup>10</sup>

The remaining thirty-nine letters (70 per cent) express varying degrees of dissatisfaction, although there is no general condemnation and no denial of a certain percentage of brilliant results. The general tendency is to place great emphasis on such items as continued pyuria, bladder irritability and urinary frequency, although the patients are able to void and are mostly without residual urine. Frequent reference is also made to such postoperative complications as hemorrhage, pelvic cellulitis, stricture, incontinence, late recurrence and infected residual prostatic tissue as a cause of impairment of general health on a focal infection basis.

It is unnecessary to state that many letters refer to patients reported cured by resection who had traveled to other clinics for relief by prostatectomy or local treatments of the bladder without the knowledge of the resectionist. Also a number of urologists report the necessity of subsequent prostatectomy in their own cases of unsuccessful resection. Under this circumstance Hepler's<sup>3</sup> patient inquired "Why didn't you do that in the first place?"

Hepler's<sup>3</sup> experience has been that many patients were not relieved of their prostatism even though there was no residual urine, and Qumby states definitely that "with the very large or badly infected prostate, we get better results from the open operation." Delzell<sup>8</sup> believes "that it is possible to perform resection in about 90 per cent of cases," although "practical results do not justify this operation in over 25 per cent." Beer<sup>10</sup> suggests that "mild prostatitis are frequently worse off after resection," on account of increased infection and urinary frequency following the removal of "some" of the prostatic tissue, despite the reduction in the amount of residual urine. The opinion of many urologists is expressed by Herman, who says that "few resectionists can employ the method as a routine with final results comparable to those obtained by selective methods." A new idea is brought forth by Paine<sup>3</sup> in the suggestion that "the new lease of life and the rejuvenation which elderly men seem to have after a successful enucleation of the prostate depends to a large extent on the removal of the focus of infection" as well as relief from residual urine. He believes that transurethral resection fails in this respect. Of 253 consecutive one year replies received from my own perineal prostatectomy patients in answer to the question "Do you consider yourself well, improved or unimproved?" 82.5 per cent classify themselves as well and 16.3 per cent as improved (table 3). Replies to the same question from a large series of one year resection patients should make an interesting comparison. Keyes and Ferguson say "One fears that ten years after operation, many of the patients may suffer recurrence such as occurs even after prostatectomy." Decidedly, the consensus is that enucleation is more dependable with respect to completeness and permanence of symptomatic relief.

#### MULTIPLE SITTINGS

"Surgeons should aim at a higher ideal" than to advise a certain operation knowing that "repetition may be necessary in order to effect a cure." Randall's<sup>3</sup> condemnation of multiple sittings is concurred in by all but two of the nineteen urologists who voluntarily refer to this phase of the subject, the general thought being that prolongation of the procedure tends to nullify resection's chief advantage. According to Hyde,<sup>3</sup> "there is less trauma to the patient, both physical and

mental, with prostatectomy than with multiple resections," and Bumpus<sup>3</sup> states that "suprapubic prostatectomy makes a shorter stay in the hospital than multiple transurethral resections." If resection is a more tedious ordeal for the patient than prostatectomy, as some urologists (including myself) think, this is doubly significant with respect to multiple resections, although "some patients prefer two, or even three, resections rather than undergo prostatectomy" (Livermore's<sup>6</sup>). Nesbit<sup>3</sup> believes that "the very large gland, which might require multiple resections may be removed as safely by perineal prostatectomy." Colston<sup>3</sup> writes "We are unanimous in condemning multiple resections."

#### THE OPERATION

"For the very large prostate, the 'whittling operation,' as some have called it, is not only inappropriate but even ridiculous, when in a few minutes the hypertrophied lobes may be enucleated in toto, with a permanent cure." By way of interpretation of this statement by Young,<sup>3</sup> I assume personal responsibility for the opinion that resection except in selected cases is infinitely more tedious and tiring and from the point of view of surgeon and patient alike, besides being more time consuming, less certain as to results and no less hazardous than perineal prostatectomy. In other

TABLE 3—Late Functional Results Following Perineal Prostatectomy\*

Patient's Own Opinion	Perineal Prostatectomy	Resection

Improved	16.3%	?
	98.8%	

\* Based on 253 consecutive questionnaire responses after one year.

words, as a result of the expenditure of greater effort on the part of both surgeon and patient, less has been accomplished. Therefore, since these advantages rest with perineal enucleation, the answer to the question as to wherein then lies the justification for routine resection is that certain skilful operators have succeeded in bettering their results of suprapubic prostatectomy by this method. In confirmation of the advantages of perineal enucleation as enumerated, Alcock<sup>8</sup> has graciously reiterated "If I could do a perineal prostatectomy as well as Dr. Young can, I would probably do all my cases by that method."

#### PRELIMINARY DRAINAGE

To the conservative and to those who have established conspicuously good records in prostatic surgery, the necessity for preoperative drainage is axiomatic. One might just as well seriously question the advisability of hemostasis. If one factor were to be named largely responsible for the dramatic lowering of the prostatectomy mortality rate from 40 per cent to practically nil, it would be this. Yet one notes a tendency among resectionists toward minimizing this essential process. For instance, Bumpus and Massey<sup>18</sup> go so far as to say that "transurethral resection has diminished the necessity for preliminary preparation in the majority of cases of hypertrophy of the prostate." A lessening of the drainage period has been urged by Kretschmer<sup>19</sup>

18 Bumpus H. C. and Massey B. D. Transurethral Resection Does It Require as Extensive a Preoperative Preparation as Prostatectomy? California & West Med 46: 89 (Feb.) 1937.  
19 Kretschmer H. L. Transurethral Resection Ann Surg 104: 917 (Nov.) 1936.

and others, although Davis<sup>20</sup> considers that "adequate preliminary treatment is of paramount importance continued until the renal function has become stabilized." Emmett<sup>14</sup> of the Mayo Clinic states that "drainage by catheter is employed only if nitrogen is retained in the blood," while Thompson<sup>21</sup> of the same clinic says "Let me reiterate that preliminary drainage is an absolute essential." For patients with only moderate amounts of residual urine and without impairment of renal function, it is conceded that preliminary drainage may be fairly safely dispensed with before either operation, whereas with a distinct increase in the blood nitrogen content the conservative surgeon would do well to omit this precaution before neither operation. In other words, drainage is essential for poor risks before either operation and for good risks before neither. The logical conclusion is that the duration of drainage should be fitted to the patient rather than to the operation. Personally, I much prefer to drain than be sorry and follow this procedure with all but conspicuously good risks.

The great increase in the number of resections as compared with the number of prostatectomies has been noted by many urologists and is generally recognized. Beebe<sup>1</sup> states that "few clinics in the first thirty years of this century were able to report over 1,000 cases in whom prostatectomy had been indicated and performed, whereas in the last five years a number of clinics have reported over 500 and some even 1,000 to 2,000 cases." This conspicuous increase is explained by the resectionists on the theory that patients now have less fear of prostatic operations and consequently seek relief earlier, but this belief is not shared by others, who claim that many of the operations are unnecessary. One writer suggests that "perhaps it is in such cases that preliminary treatment may be discarded." At any rate, it seems safe to make the statement that, with but few exceptions, the patient in no need of preprostatectomy or pre-resection drainage is in no immediate urgent need of a prostatic operation.

#### THE ESSENTIAL DIFFERENCE

As outlined in the preceding paragraphs, it is the opinion of the majority of urologists that the risk of resection is less than that of suprapubic prostatectomy and about the same as that of perineal prostatectomy (all in good hands), that the duration of the preliminary drainage should depend on the condition of the patient rather than on the method, that the actual procedure is more tedious and time consuming and that, in general, symptomatic relief is less complete and permanent than that following enucleation. The question which then naturally arises is "What is the essential difference between perineal prostatectomy and transurethral resection, and wherein lies the advantage of the latter?"

On the basis of mortality rate, the advantage of resection over operation by the suprapubic route is obvious, but the advantage over operation by the perineal route rests chiefly (if not solely) on the number of postoperative days in the hospital. My own average period of hospital care following perineal prostatectomy is twenty-one days, while Hinman,<sup>11</sup> following his method of plastic closure of the prostatic capsule and perineal incision, has reduced his average figure to seventeen days. He says that "the functional results (of his plastic

closure operation) are as permanent and as good as, or better than, results achieved by any other method." One may be certain that this is an accurate, conservative statement.

Emmett<sup>14</sup> has recently reported an average post-operative period in the hospital of eight days, "remaining almost constant, year to year," following resection at the Mayo Clinic. It would seem reasonable to consider this figure as a minimum average. Giving the full benefit of the doubt to the resectionist by omitting all consideration of later hospitalizations and subsequent "ambulatory treatments," and assuming that the eight-day patients, as well as Hinman's seventeen-day patients, are discharged permanently well, one must conclude that the essential difference, the best available figures for each method being compared, is nine days, which seems rather a cheap price to pay for dependability and permanence.

#### INCONTINENCE

If a substantial increase in the sales of the Cunningham incontinence clamp coincident with the advent of transurethral resection may be considered as an index of the number of cases in which incontinence results from this procedure, it may be stated that the frequency of this complication has been greatly underestimated. A communication from the Bard Company states that the estimated yearly sales of the clamp averaged from 100 to 150 during the ten years preceding 1928 and gradually doubled during the ensuing years to 1933, since which time precise figures are available, these being 384, 473, 720, 684 and 1,008 for the years 1933 to 1937 inclusive. On the basis of 432 for the first quarter of 1938, total sales for the current year should reach 1,700. It is "an ill wind that bloweth no man good."

#### CONCLUSIONS

My own thought has always been that the entire situation may be summed up concisely and fairly accurately by the statement that, whereas resection is the shorter, prostatectomy is both safer and surer. Sacrificing conciseness and brevity for greater accuracy, one may, in the light of information recently obtained, paraphrase this aphorism as follows:

Resection is usually shorter than prostatectomy, as measured by days in the hospital but not as measured by days of convalescence or by actual operating time.

Perineal prostatectomy is decidedly safer than resection in the hands of some surgeons (on the basis of their own resection figures), although there is no essential difference when the best available figures for each procedure are compared.

Prostatectomy by either route in good hands is surer than resection, in that the majority of surgeons agree that enucleation gives more dependable assurance of complete and permanent symptomatic relief.

Concerning resection, the extreme skepticism of one small minority (the nihilists) is balanced by the unbounded enthusiasm of another small minority (the panresectionists), while the great majority, exceeding 80 per cent, recognize both advantages and limitations and favor selection of cases, as determined largely by the size of the gland.

A skilful few, however, rather than fit the operation to the patient have succeeded in fitting the patient to the surgeon.

The choice as to the method of operation is individual so far as the patient is concerned and personal so far as the surgeon is concerned.

20 Davis, T. M. Transurethral Prostatic Resection with Report of 748 Cases. *South. M. J.* 28: 693 (Aug.) 1935.  
21 Thompson, G. J. Transurethral Surgery. *Texas State J. Med.* 32: 735 (March) 1937.

Patients are well served and good results obtained by both groups of skilful extremists

The mortality rate and the functional results of transurethral resection bear a definite relationship to the skill and experience of the operator

The consensus indicates that the public demand for transurethral resection is showing a tendency to decrease

The number of urologists who are tending to decrease their percentage of resections is distinctly greater than the number tending to increase this percentage

The chief if not the sole advantage of resection in the best hands over perineal prostatectomy in the best hands consists in the saving of from nine to fourteen days of postoperative hospital care

Abuse by the incompetent and the unscrupulous has caused undeserved discredit to a very valuable procedure

Transurethral resection, after passing through a typical trial and appraisal cycle, including both abuse and overcorrection, is now approaching the final stage of stability, with a clearly defined field of usefulness

It is my belief that these conclusions, which are not based on my own opinions, are essentially those which any fair-minded person would inevitably reach after reading the same hundred letters

#### SOME REFINEMENTS IN THE TECHNIC OF TRANSURETHRAL PROSTATECTOMY

REED M NESBIT, M D

ANN ARBOR, MICH

The purpose of this paper is to discuss some of the most serious complications which have tended to discredit transurethral resection and to suggest certain refinements in the technic of operation which have been demonstrated to avoid them. These complications are, first, infection and sepsis during the immediate postoperative period, second, traumatic stricture of the pendulous portion of the urethra, and, third, persisting urinary dysfunction, with cloudy infected urine, delayed urinary sepsis and occasional recurrent hematuria

Transurethral resection has become an accepted procedure by all urologists, but little agreement exists regarding the indications for and limitations on this operation. Many able and experienced surgeons believe that it should be performed only for small median lobe hypertrophies, median bars and vesical neck contractures. Other genito-urinary surgeons of equal experience and skill in prostatic operations feel that all obstructive lesions of the bladder outlet, regardless of size, should be dealt with by the transurethral approach. Surely the proponents of extreme conservatism are expressing honest opinions based on personal experiences, they cannot be accused of being entirely wrong in their views. Likewise the advocates of resection in all cases, such as Alcock Bumpus, Davis and Thompson, cannot be accused of being entirely wrong. Perhaps both groups are entirely right. Perhaps these divergent opinions are based on the experiences of men whose technical abilities with this

procedure are vastly dissimilar. Surely this operation, recognized by all as having a place in some cases, must be sound in principle. The inability of any able surgeon or group of surgeons to perform properly any sound operative procedure in all cases should not condemn that operation to the scrapheap. Neither should the superlative technical ability of a few surgeons give license to the universal practice of any difficult operation. Most urologists agree that transurethral resection is indicated in those cases in which complete removal of abnormal tissue can be accomplished. The great and outstanding exception to this rule is in cases of sharply localized early malignant changes in which certainly a perineal exposure with immediate biopsy and radical prostatectomy offers the best hope of survival from cancer of the prostate.

Since infection plays an important part in the morbidity and mortality of operation, its control and prevention are imperative. To perform a complete transurethral prostatectomy and then have the patient die of sepsis is an unhappy and sad commentary on the surgeon and the operation he has performed. It is probably true that sepsis occurs more frequently as a result of the introduction of bacteria which are entirely foreign to the patient than from organisms which the host brings with him when he comes to the surgeon. The careful preparation of the patient for catheterization or instrumentation and the aseptic care of catheters and drainage systems both before and after operation will, in a large measure, reduce sepsis to an unusual complication. It has been the practice at the University Hospital for the past four years to employ a closed, sterile irrigator drainage system for all patients requiring catheter drainage before operation, and its use is part of the postoperative routine. The entire system, wrapped in a sheet is sterilized in the autoclave. Each ward has an available supply. Catheters are introduced with aseptic technic, and the irrigating drainage system is immediately connected. The reservoir bottle is filled with 2 per cent boric acid solution in most cases. When the bladder is grossly infected, 0.25 or 0.50 per cent acetic acid is used. Frequent irrigations with this solution quickly clear up most severe bladder infections. The irrigator system is never disconnected when once put into use, the object being to provide drainage and to prevent the contamination of the bladder by accidental inoculation with organisms foreign to the host. The absence of sepsis which has resulted from the employment of these methods has justified a great enthusiasm for them.

The ultimate result of a perfectly performed resection has occasionally been marred by the development of urethral stricture. This unhappy sequel has been observed by all resectionists who have checked up on their patients but unfortunately has received practically no recognition in the literature. Bumpus aptly remarked that one had better perform some other type of prostatectomy than do a successful resection and then leave the patient with a lesion of the urethra infinitely more debilitating and difficult to treat than his prostatism.

Resectoscopes must of necessity have sheaths of large caliber, most instruments in common use being 28 or 30 French in size. Not all male urethras possess this caliber. Some urethras are normally small, some are small because of previous disease and many are limited in size because of the loss of elasticity which the urethra shares with other tissues in later life. This inelasticity is invariably confined to the penile portion. It has been

the practice of resectionists to dilate such urethras until they can accommodate the resectoscope. Some have even performed internal urethrotomy to attain the desired accommodation for large instruments. In either event the dilation has amounted to rupture or divulsion of the urethral mucosa, which can only result in stricture. Such an injury invariably occurs in the pendulous portion and at the penoscrotal angle where strictures are apt to contract rapidly and are notoriously hard to dilate. The anticipated success of resection has doubtless led to occasional unwarranted disregard of the urethra and irreparable result in some cases.

Fig 1—Irrigator drainage system

About a year ago Hugh Cabot suggested a method of averting this disaster to his colleague Dr. Thompson, who subsequently reported its use in one case.<sup>1</sup> In the discussion of Dr. Thompson's report, Dr. Cabot said, "There appears to be no doubt that stricture of the urethra and periurethral abscess with resulting fistula, most commonly at the penoscrotal angle, have been more than occasional complications of transurethral prostatectomy. It is of interest to recall that more than sixty years ago Bigelow encountered the same problem in his masterly reorganization of the operation of lithotomy which he transformed into litholapaxy. He insisted that large instruments were essential to success. Commonly enough, these could be passed but he laid down in one of his earlier papers the doctrine that, in the presence of a small urethra, litholapaxy should be done through a perineal urethrotomy and not through a divulsed urethra. Therefore, I make bold to suggest to the gentlemen of Dr. Thompson's generation, who are developing the operation of transurethral prostatectomy, that they abandon preliminary dilatation of the urethra, that if the instrument will not pass without difficulty they will be well advised to resort to a perineal boutonniere through which to carry out their operation. This wound will require no sutures, will not prolong convalescence and injury to the anterior urethra will be avoided."

Since the enunciation of these sound principles my associates and I have employed perineal urethrotomy in all cases in which the urethra has not easily admitted the free passage of a 30 French steel sound. We have

found it preferable to perform this simple procedure rather than meatotomy when the meatus is small, since even the most carefully managed meatotomy would occasionally result in stricture. Also in a few rare instances in which unusual maneuverability of the instrument was desired and the prostate was excessively long, we elected to make this approach even though the urethra could have easily accommodated the standard resectoscope.

A simple method of performing this procedure consists of introducing a grooved sound of 20 French caliber into the urethra. Gentle pressure on the handle of the sound allows its curve to project into the perineum, where, with its overlying structures, it can be grasped by the thumb and index finger of the left hand. An incision 2 cm long which passes directly down on the sound is now made. The cut edges of the urethral mucosa and the full thickness of the bulb are grasped in Allis forceps and transfixed by anchor sutures. Through this incision the resectoscope sheath is easily and safely introduced. At the end of the operation the catheter or Foley bag may be introduced either through the incision or through the entire urethra, depending on the amount of pre-existing urethral disease. With many showing inflammation of the pendulous portion of the urethra we have felt it desirable to avoid the danger of catheter trauma and have brought the catheter out through the perineal wound. When the catheter is brought out through the urethral meatus we usually take one stitch in the bulb at the site of the urethrotomy incision. A small gauze pack is then introduced into the wound and left in twenty-four hours. If the wound is not packed in this way the skin frequently closes by first intention and a small subcutaneous abscess is apt to develop.

The use of perineal urethrotomy would also permit the safe use of instruments of considerably larger size than those now available, since the bulb and membranous portion of the urethra have a lumen much greater than 30 French. Such instruments would be advantageous in many instances in which rapid resection or removal of large amounts of tissue is necessary. At our suggestion an instrument of 33 French caliber has been made available through the cooperation of Mr. Frederick Wappler. This instrument has been used in a considerable number of cases and the obvious anticipated advantages of its increased size have been realized. Using the standard size McCarthy resectoscope we have regularly been able to remove 1 Gm of tissue a minute in the average case, while with the larger instrument we have found that about 2 Gm of tissue a minute is the average.

During the past year perineal urethrotomy has been performed in 11 per cent of all resection cases. In no instance has the procedure resulted in any complication,

Fig 2—Anchor suture through urethral mucosa and bulb

<sup>1</sup> Thompson, C. J. Perineal Prostatic Resection. *Proc. Staff Meet. Mayo Clin.* 12: 360 (June 9) 1937.

either immediate or remote, that has in any way contributed to postoperative morbidity or discomfort to the patient. On removal of the catheter all but two patients have voided part of their urine from the incision. Many have had completely healed wounds in three days. The longest period of perineal drainage was fifteen days. Complete wound healing occurred in an average of nine days in the entire series. Postoperative check-up examinations on the majority of these patients have shown absence of any evidence of stricture in the region of the bulb, and in most instances one could scarcely see or feel any evidences of the urethrotomy scar.

During the early days of resection there appeared authoritative statements saying that the enlarged gland would shrink in size if one but removed the tissue actually giving rise to obstruction, channelizing the prostatic urethra. Experience has shown that this advice was wrong, in that a gland so resected not only fails to shrink but frequently acts as a focus for urinary sepsis. The researches of Reuben Flocks<sup>2</sup> have been of tremendous importance not only in providing an understanding of the pathologic anatomy of prostatism but also in explaining the reasons for many of the postoperative complications which have tended to discredit this operation. Flocks has shown that about 90 per cent of the hypertrophic mass of tissue derives its blood supply from the urethral arteries, which enter the prostate in the region of the internal sphincter and course distally in the substance of the lateral lobe. In transurethral resections these vessels are cut across and thrombosed at their point of entry into the gland. If the tissue supplied by these vessels is not removed at operation, it necessarily undergoes varying degrees of devitalization and may become infarcted throughout a considerable area. Patients harboring such septic infarcts may suffer recurrent obstruction, persisting abnormalities of urinary function, urinary sepsis and delayed hemorrhages. Their primary need for prostatectomy has not been supplied, and relief from the disability is dependent on the completion of the prostatectomy by either the transurethral route or some other. Thus the researches of Flocks, as well as clinical experience, have abundantly demonstrated that transurethral resection must be, in fact, transurethral prostatectomy. Surgeons who perform this operation must be sufficiently aware of their own technical limitations to employ it only when the gland is of such a size that more or less complete removal of tissue can be expected.

The limitations of this presentation do not permit a description of our technic of transurethral prostatectomy. However, one feature of the technic, which we believe is essential to complete removal of the gland, will be discussed. I refer to third dimensional perception. The instruments which are regularly used to perform this operation provide only visual perception of two dimensions. Perception of the third dimension can be obtained only through the sense of touch by rectal palpation, enabling one to estimate accurately the amount of tissue which must be excised. Pressure exerted upward or medially by the examining finger also aids materially in bringing tissue into the path of the cutting loop or blade of the instrument. Guided thus by the sense of touch as well as by sight, one can avoid the dangers of cutting too deeply in vulnerable areas and can carry resection of tissue accurately down to the readily recognized capsule of the gland.

In the past it has been our practice to perform rectal palpation at numerous times during the course of operation. While the actual cutting maneuvers were being carried out an assistant constantly maintained digital pressure over the area of excision, guiding the operator as to the thickness of the prostatic mass as well as warning him against dangerous areas. Feeling the necessity for simultaneous palpation and cutting by the operator as an added factor of safety as well as of accuracy, we suggested that our instruments be modified to permit this refinement in technic. Such modifications of the resectoscope have been ingeniously worked out by Mr. Wappler, so that the operator can now work entirely with one hand, leaving the other hand free to guide safely the excision of tissue. The use of this modified instrument not only has permitted a refinement of our technic from the standpoint of accuracy and safety but also has permitted an increase in the speed of resection without danger.<sup>3</sup>

#### SUMMARY

Transurethral prostatectomy, when properly performed, shows to advantage over other types of prostatectomy in that it carries a very low mortality rate, the morbidity is less and the period of hospitalization is greatly reduced. An important advantage to the patient is that he is saved the distress and discomfort attendant on the operative wounds incident to open operations.

Transurethral prostatectomy is a sound procedure demanding a high degree of technical skill for its proper execution. Any surgeon possessed of this skill can perform the operation with the expectation of obtaining excellent postoperative results. Such a surgeon will recognize the limits of his own dexterity and perform the operation in only those cases in which he can expect to perform a more or less complete prostatectomy. Other cases he will reserve for more appropriate surgical procedures. His dexterity, skill and experience may warrant his performing resection in 100 per cent or, perhaps, in only 10 per cent of cases.

The able resectionist will guard his patients against morbidity and mortality from needless loss of blood and from sepsis, since these complications have been largely eliminated by modern methods. He will prevent traumatic stricture occurring as a devastating sequela of an otherwise satisfactory prostatectomy.

The able resectionist will continue to bring relief to increasing numbers of sufferers, many of whom will continue to be his medical colleagues.

Refinements in our technic and improvements in our armamentarium have increased the scope of transurethral prostatectomy and have tended to decrease the limitations on it.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. DAVIS AND NESBIT

DR. H. C. BUMPUS, JR., Pasadena, Calif. Dr. Nesbit emphasized the efficacy with which sepsis can be avoided by using a closed irrigating system both before and after operation. I have employed such a system for five years and have had a minimum of febrile reactions. Formerly, when bladders were irrigated at stated intervals, the introduction of organisms foreign to the host was the rule, for the distal end of the catheter was invariably contaminated. The insurance of good functional results depends on the removal of all the obstructing prostate, not just a portion of it, and this must be done without producing other obstruction in the form of urethral

<sup>2</sup> Flocks, R. H. Arterial Distribution Within the Prostate Gland. Its Role in Transurethral Prostatic Resection. *J. Urol.* 37: 524-548 (April) 1937.

<sup>3</sup> Nesbit, R. M. A Modification of the Stern-McCarthy Resectoscope Permitting Third Dimensional Perception During Transurethral Prostatectomy. *J. Urology* to be published.

stricture Dr Nesbit's report of successfully employing Dr Cabot's suggestion of working through a perineal incision is valuable. This procedure insures against strictures of the anterior part of the urethra, which in the past have been a serious complication of resection. The perineal approach has the added advantage of making it possible by passing a larger caliber instrument to shorten the duration of the operation by more rapidly removing portions of the obstruction. Dr Nesbit's modification of the resectoscope that permits the palpation of the gland while it is being operated on will appeal to all who have formerly depended on the finger of the assistant. Dr Davis presented a poll of what men throughout the country think about transurethral prostatic surgical procedures. The conservatism of this method rather than the enthusiasm for an ingenious instrument and the desire to develop a personal technical skill with it, to my mind, is impressing the urologist more and more. I am in a more fortunate position than Dr Davis in that I have seen prostatectomy under what may be called the three periods during the last twenty-five years under standardized conditions. The first period was before it was possible to estimate preoperative risks by determinations of the blood nitrogen level. The second period may be designated as that in which combined preoperative tests plus the splendid and perfected operative technique developed by Dr Hunt at the Mayo Clinic seemed to have made suprapubic prostatectomy as safe an operation as is humanly possible. Finally, I have participated actively in, the third period of prostatic surgery and can, in retrospect, judge the progress made. When there is available a method of relieving prostatic obstruction that results in less than 2 per cent mortality in patients over 70, may I submit in defense of myself and the other seven members of what Dr Davis calls the totalitarian group the question whether we must apologize for our belief that if the urethra will admit the instrument the gland can be successfully and satisfactorily removed.

DR ALFRED I. FOLSOM, Dallas, Texas. Dr Davis would have one believe that in the days of perineal prostatectomy and suprapubic prostatectomy these two procedures were handed down as Minerva was, "full panoplied from the head of Jove," perfect in all their details. Let no one hark back to the good old days when everything was perfect, because things were not perfect at all. I want to emphasize what Dr Davis said. Prostatic resection is going to become, in an increasing degree, a specialty within a specialty. I do not agree with Dr Davis that it is much more tedious and tiring for the patient, because it isn't, so far as my observations go. It is a highly technical procedure and therefore ultimately is going to rest in the hands of the few surgeons who have a particular type of skill and a particular type of nervous system which will allow them to piddle at this job, because it is a piddling operation. It is a nerve racking and a trying thing to the operator. I would infinitely rather do a suprapubic prostatectomy than a prostatic resection. I have been doing prostatic resections now for seven years and I have had satisfactory results. Is there any reason why I should continue this policy if I were not getting satisfactory results? If all these horrible bugbears that have been depicted were materializing, is there any reason why I should continue this rather than go back to the good old halcyon days of suprapubic prostatectomy, when I had no trouble whatever? Hunt a number of years ago reported from the Mayo Clinic on suprapubic prostatectomy that after 70 the mortality jumped amazingly, and that has been every one's experience. Gundersen reported 100 cases of resection in men over 70 with a mortality of something like 2 per cent. That statement alone is enough to satisfy those who are not convinced that there is real merit in this operation. I have used Dr Nesbit's procedure, it is amazing how nicely it works, and it does give one an amazing movability of the instrument.

DR SIDNEY OLSEN, San Francisco. There are definite indications for the various procedures. The prime factor is the vesical type of obstruction, whether it is a bar of the median lobe or of the posterior commissure or a generalized contraction of the neck, such as one sees with the ring type of hypertrophy and occasionally with malignant change. With the intravesical and the intra-urethral type of enlargement one has another consideration to make. Infection is the big factor, and if its likelihood both before and after operation can be cut down, a lot will have been accomplished. I would ask Dr Nesbit if

he has been trying drainage through the perineum, as he does with external urethrotomy prior to or at the time of resection. Another infection that sometimes prolongs the illness is vesiculitis, which is commonly overlooked. I use vasoligation as a routine to cut down the likelihood of epididymitis, therefore I feel that a course of massage sometimes is indicated following the resection, to clear up some of the pyuria. One of the shortcomings of transurethral resection is that with early carcinoma that can be palpated through the capsule one naturally will think of a perineal procedure for biopsy at least, and probably complete enucleation of the prostate and capsule. But many times a nodule of carcinoma is situated in one of the hyperplastic lobes, and in the transurethral resection one does not always penetrate so deeply as to pick it up. However, with a perineal operation the chances are that one will be able to pick up such a small nodule, at least in cutting through the capsule or in removing the gland in toto. I feel that any type of prostate can be removed by the perineal route unless the patient is physically unable to get in the proper position.

DR B. H. HAGER, Los Angeles. Drs Davis and Nesbit have given a comprehensive analysis of the present day attitude toward prostatic surgical measures. Conflicting views are naturally in evidence, some of which are none too charitable and argue for an unbiased evaluation. I am sure it is not the intention of the speakers to convert urologists to any single procedure. There is no denying that all methods of approach to the removal of the prostate have decided merit. The remarkable results and low mortality from the various techniques now employed are established facts. To adapt a procedure to the patient rather than the patient to the procedure may not always be regarded as good surgical judgment, however, it becomes a matter of personal judgment, based on training, experience and dexterity. In the hands of experts in their respective fields, the choice of operation apparently offers no problem. For the less specialized the greatest good will come from the selection of the method most suitable to the patient and the operator's skill.

DR N. G. ALCOCK, Iowa City. If one is going to relieve obstruction one has to take out tissue. The argument is that with prostatic resection that can be done. Dr Nesbit has made a great contribution to this very thing by using the larger instrument, so that it can be done in a shorter period. I prefer never to operate on a patient for more than forty-five minutes at a sitting. In the average case one should remove from a gram to a gram and a half a minute, and with the larger instrument I know it can be done much more rapidly than that. In fifty consecutive operations done in April and the first part of May the average amount of tissue removed was 31 Gm., which is getting fairly close to taking out the entire prostate. Of course that excludes cases in which one removes only 8 or 10 or 12 Gm., which I think it only fair to exclude because one wouldn't have done a prostatectomy in them. Of these fifty patients there were eight, or 16 per cent, over 80. There are two things that I want to know about any series of prostate operations that are reported: (1) the age in the decades, and (2) the mortality rate in the decades. I believe that if one takes patients with prostatic disease as they come the average age is going to be close to 73. Of these fifty there were eight, or 16 per cent, over 80, and there were 75 per cent over 70. I also want to know how many patients died during the period this series covered. When I had done 1,500 of these operations, eighty-eight patients had died, but during that period I had had 129 deaths among patients who had not been operated on. Knowing those two things, one can visualize the type of series under consideration and get some gauge of the value of the procedure. I think the physician should be privileged to do the operation that he can do best for the patient, and I hope the time never comes when a bureau in Washington or elsewhere is going to tell me what I am going to do for my individual patient. As urologists we are not going to settle this question of perineal operations or suprapubic prostatectomies or resections. The one who is going to decide that is the general practitioner who takes care of the patient after we get through with him.

DR A. B. CECIL, Los Angeles. For years I have been reporting a mortality rate of less than 2 per cent with Young's perineal prostatectomy. One thing that resectoscopy has done has been to bring out the frightful death rate of suprapubic

prostatectomy, a thing never known before. In various clinics throughout this country it has varied from 17 to 90 per cent. All perineal operations such as median perineal prostatectomy, Young's perineal prostatectomy and Chetwood's perineal incision had a low death rate, but with Dr Nesbit's operation the external sphincter must be carefully guarded or incontinence of urine will follow. Incontinence of urine does not follow Young's perineal prostatectomy because, as I have previously pointed out before this section, in this operation the external sphincter is carefully preserved. I see no sense in doing median perineal prostatectomy by means of a resectoscope when one can by Young's method easily expose the prostate and enucleate the obstructing adenoma, which in my hands has required on an average only twelve minutes. I am sure that perineal resectoscopy is an unsurgical procedure and is not the high type of operation which urologists have been trained to perform and which has raised this section to the high position which it occupies. I see nothing remarkable about Dr Thompson's mortality rate, but I should like to ask why his statistics are all for patients over 70 years of age. I should like to ask what happened to patients under 70. Again one hears about hospitalization. When I speak of hospitalization I am speaking of hotelization and all other "izations" until the patient is well, and I am not speaking of persons as cured who are in danger of hemorrhage or embolus or who have burning for months or even years afterward. I am talking about patients who are out of danger and have normal functional results. Furthermore, I have had to reoperate in but one case in the many years that I have been doing Young's perineal prostatectomy.

DR EDWIN DAVIS, Omaha: I congratulate Dr Nesbit on his convincing presentation. If I were to presume to criticize any one, it would be that small minority of physicians who refuse to recognize any indications for resection rather than the small minority who refuse to recognize any limitations. I believe there is no essential disagreement. Let each do that which he does best.

## TREATMENT OF GASTROINTESTINAL TUBERCULOSIS

LEO L. HARDT, M.D.  
MORRIS WEISSMAN, M.D.  
JOHN S. COULTER, M.D.  
AND  
KARL J. HENRICHSEN, M.D.  
CHICAGO

This study comprises a group of patients known to have active, far advanced pulmonary tuberculosis complicated by intestinal tuberculosis.

In evaluating the various types of medical treatment suggested for the cure of intestinal tuberculosis, it is necessary to assume that the patients under observation are suffering from active intestinal tuberculosis. It is not our aim in this paper to discuss in detail the methods used in arriving at a clinical diagnosis; they will be submitted for publication at a later date. These methods of diagnosis were followed in approximately 553 cases over a period of five years. Fifty-five patients came to autopsy, and of these the diagnosis was correct for 86.4 per cent. Two of those who survived had tuberculous ulcers of the sigmoid flexure at the onset of treatment, as demonstrated by our proctologist, Dr Clemens Martin. These ulcers were completely healed during the course of treatment (table 1).

The literature makes no mention of any specific drug therapy in the treatment of intestinal tuberculosis, but

in general the high vitamin, high mineral diet has been advocated. Calcium therapy, intravenous, intramuscular or oral, has been recommended by some authors and heliotherapy, with or without emphasis on the diet, by others.

Ringer and Minor<sup>1</sup> in a study of thirty cases of tuberculous diarrhea in 1922 reported encouraging results with from 5 to 10 cc of a 5 per cent solution of calcium chloride given intravenously at frequent intervals.

Later Roberts<sup>2</sup> concluded from his experience with calcium chloride given intravenously in more than seventy cases that the beneficial results justified the use of calcium chloride as a standard treatment, along with heliotherapy and dietetic treatment, for practically all patients showing evidence of gastrointestinal involvement.

Cantarow<sup>3</sup> in 1931 suggested that calcium therapy for the diarrhea of intestinal tuberculosis might be beneficial through its inhibitory effect on peristalsis, through its possible beneficial effect on the local inflammatory process and through its local or general dehydrating effect. In any event, it has a tendency to relieve abdominal pain, intestinal bleeding and diarrhea in most cases.

From the many authors that could be cited concerning the efficacy of calcium therapy one would be led to believe that the two general factors involved are (1) the pharmacologic action of calcium and (2) the replacement of the calcium lost through the dehydrating action of the diseased intestinal tract, together with mineral loss through the sweat glands. Hardt and Palmer<sup>4</sup> through their experiments on intermittent heat sweats emphasized the possible demineralization in tuberculosis. Then Hardt and Sharer<sup>5</sup> reported an appreciable loss of calcium and considerable loss of chlorides through the sweat glands by normal subjects during intermittent periods of sweating.

Bauer, Salter and Aub<sup>6</sup> suggested the intravenous use of calcium to relieve certain types of intestinal and cholecystic pain.

A deficiency of calcium in the circulatory fluids leads to increased excitability of the neuromuscular system, as seen, for example, in tetany. According to the Council on Pharmacy and Chemistry, the administration of calcium salts decreases the neuromuscular irritability in such cases.

Although the diet outlined by us is adequate in calcium for the normal person, it may prove deficient because of the extra losses of calcium from the tissues through the bowel and sweat glands. The good results obtained with calcium therapy may be largely due to the replacement of calcium in the tissues, together with the pharmacologic action of calcium.

The work of Wolbach and Howe<sup>7</sup> indicates that the respiratory and the gastrointestinal tract are more susceptible to infections when there is a vitamin A deficiency. Excessive vomiting and diarrhea, in addition

to other processes interfering with metabolism of fats, might readily lead to a vitamin A deficiency<sup>8</sup>

It has been established by the literature and our clinical experience that deprivation of vitamin B<sub>1</sub> results in anorexia and gastrointestinal hypotonicity. McCarrison<sup>9</sup> as early as 1921 observed intestinal stasis and a degeneration of Auerbach's plexus in animals on diets deficient in vitamin B and diets deficient in vitamins A and B. Russell<sup>10</sup> was able to overcome anorexia by injecting units of crystalline vitamin B<sub>1</sub>. Glassberg<sup>11</sup> stated that in treating uncomplicated malnutrition he has found vitamin B concentrate helpful in enhancing appetite. Vorhaus<sup>12</sup> suggested that so-called secondary beriberi might readily be encountered in association with chronic tuberculous gastro-enteritis. He also found that, when vitamin B<sub>1</sub> deficiency is responsible for anorexia and weakness, response usually follows the

administration of 150 international units of vitamin B<sub>1</sub> daily for two weeks, when the presence of severe deficiency from vomiting diarrhea or gastrointestinal disease renders absorption of the vitamin by oral administration inadequate, he advised the use of crystalline vitamin B<sub>1</sub> solution made especially for parenteral injection.

The Council on Pharmacy and Chemistry<sup>13</sup> states that vitamin B<sub>1</sub> may be of value in correcting and preventing anorexia of dietary origin in certain cases.

The importance of vitamins C and D in the healing of intestinal ulcerations was suggested by Grant<sup>14</sup> in 1926 in her work on guinea pigs. McConkey,<sup>15</sup> in 1929, applying the same principle to patients suffering from

intestinal tuberculosis, used cod liver oil and orange or tomato juice and reported encouraging results. An increased need for vitamin C seems definitely indicated. Faulkner and Taylor<sup>16</sup> studied fifty patients with various infectious diseases who were known to be on diets otherwise adequate in vitamin C, in the presence of chronic, active infection such as advanced pulmonary tuberculosis, additional doses as large as from 300 to 500 mg. were required to bring the blood value up to normal and maintain it there. Radford, de Savitsch and Sweany<sup>17</sup> studied the effects of vitamin C in a series of 111 tuberculous patients. There seemed to be a slight improvement in the blood picture of those treated with daily doses of 250 mg. of crystalline vitamin C over the control group and to a slight extent over those receiving 500 cc. of orange juice daily.

Direct exposure of the skin to ultraviolet rays from the sun or from artificial sources results in the formation of vitamin D within the organism, but the Council on Pharmacy and Chemistry does not recognize statements or implications that vitamin D has all the beneficial effects of exposure to sunshine. Since it has been shown by Tonney, Hoeft and Somers<sup>18</sup> that the ultraviolet content of sunshine in Chicago during October, November, December, January and February is seldom sufficient to produce a minimum erythema dose, it became necessary to resort to artificial radiation instead of natural sunlight in our series of cases. The dose was the same as that adopted by Coulter and Carter<sup>19</sup> in the treatment of pulmonary tuberculosis with ultraviolet radiation. The radiation from both natural and artificial sources was administered by a modified Rolher method to secure a faint erythema over increasing areas of the body, starting at the feet.

Erickson,<sup>20</sup> in a study of eighty-one patients treated with ultraviolet rays at Saranac Lake, N. Y., found that 24.7 per cent had entire relief from symptoms, 47 per cent were much improved, 13.5 per cent were less though definitely improved and 14.8 per cent were unimproved. Some systemic improvement occurred in 85 per cent. The patients were followed for an average of from twelve to eighteen months after symptoms had ceased.

In a series of 360 patients treated with artificial heliotherapy Brown and Sampson<sup>21</sup> found that 24 per cent were apparently cured, 25 per cent were markedly improved and 33 per cent were slightly or considerably helped, while 18 per cent obtained no benefit. In other words, 82 per cent showed signs of improvement.

It is reasonable to assume that when pulmonary tuberculosis is complicated by intestinal tuberculosis a relative avitaminosis and a demineralization are likely to exist. Therefore the need of a high vitamin and high mineral diet for the relief of intestinal involvement becomes apparent. It was our object to give a practical application of the value of a high vitamin, high mineral smooth diet, of calcium therapy and of heliotherapy. We arbitrarily limited our study to patients who had been under treatment for six months or more. The

groups were treated as follows To study the comparative efficacy of the methods we divided our patients into eight groups

Group 1-A was given the high vitamin, high mineral, smooth diet, plus ultraviolet radiation

Group 1-B was given the same diet as group 1-A, without the radiation

Group 2-A received calcium gluconate 15 grains (1 Gm) by mouth a half hour before meals, plus the diet, plus ultraviolet radiation

Group 2-B received the same treatment as group 2-A except for the ultraviolet rays

Group 3-A received 10 cc of a 10 per cent solution of calcium chloride intravenously twice a week, plus the diet, plus ultraviolet rays

Group 3-B received the same treatment as group 3-A except for the ultraviolet radiation

Group 4-A received 10 cc of a 10 per cent solution of calcium gluconate intramuscularly two or three times a week, plus the diet, plus ultraviolet rays

Group 4-B received the same treatment as group 4-A except for the radiation

All patients were advised to keep the abdomen warm by wearing a flannel abdominal binder Those suffering from constipation were advised to use liquid petrolatum or plain agar as occasion demanded Those with severe diarrhea were given bismuth preparations and opiates as a temporary measure to control it Incidentally, we found that proper care of the mouth is useful from the standpoint of prophylaxis This fact was arrived at in a careful study of fractional sputum examinations in a series of twenty-one cases We were able to show definitely that chewing paraffin and expectorating for one half to three quarters of an hour cleanses the mouth more thoroughly than the use of ordinary mouth washes A detailed report will be submitted for publication at some future date

The diet was smooth and of high vitamin, high calory and high mineral content In cases of excessive perspiration or those of prolonged vomiting or diarrhea, we increased the mineral content by administering from one-half to 1 teaspoonful of table salt in twenty-four hours As a diet we feel that the one outlined by Bergen and Sister Victor<sup>22</sup> is of value in the treatment of intestinal tuberculosis as well as other chronic infections of the bowel The general plan of the diet we administered was similar to that described by these authors Calcium and phosphorus in adequate amounts were supplied by milk, while vegetables, fruits, meats, liver and eggs contributed the required iron Vitamin B, the appetite-stimulating vitamin, was afforded by brewers' yeast tablets, bananas oranges and tomatoes, while milk butter and green vegetables furnished the necessary vitamins A and D Cod liver oil furnished an additional amount of vitamins A and D Each patient was advised to reinforce the diet by taking from 4 to 6 ounces (120 to 175 cc) of orange juice and the same amount of tomato juice daily, in order to get an additional supply of vitamin C (Mimeographed copies of our diet list will be furnished on request)

In paralleling the pulmonary and intestinal pictures we aimed to obtain a common measure of the abatement or aggravation of the symptoms Therefore in evaluating the pulmonary progress of our patients, we found it convenient to deviate from the strict National classi-

fication, without essentially violating its principles We have classified the pulmonary state of our patients as "improved," "stationary" or "worse" "Improved" is a designation applied to states from arrest to quiescence By "stationary" we refer to that vague state of abatement of symptoms attended with a fair degree of comfort but with no pronounced tendency to definite arrest, recovery or aggravation Admittedly, the personal equation will enter greatly into the evaluation of that state, hence it is a somewhat defective classification "Worse" is self explanatory

We have also taken into consideration the various surgical measures employed so far as the pulmonary condition is concerned and have tabulated them in order to determine whether or not the surgical procedure may have some bearing on the improvement not only in the pulmonary but also in the gastrointestinal condition (table 2)

The criteria of gastrointestinal improvement are based on comparison of the symptoms, physical appearances and laboratory examinations, including x-ray and proctoscopic studies and complete analysis of the blood, before treatment is instituted and six months or more after treatment

TABLE 2—Collapse Therapy Its Apparent Bearing on the Treatment of Gastrointestinal Tuberculosis

Group	Gastro Intestinal Condition Improved	Collapse Therapy	Gastro Intestinal Condition Stationary	Collapse Therapy	Gastro Intestinal Condition Worse	Collapse Therapy
1 A	14	10	6	6	3	1
1 B	23	19	7	4	9	3
2 A	22	19	2	2	1	1
2 B	27	23	9	7	8	6
3 A	20	13	2	1	2	1
3 B	18	16	3	0	9	4
4 A	19	17	3	2	3	1
4 B	20	17	3	3	3	2
	163	134	37	25	38	19

In brief, the general group of gastrointestinal symptoms at the onset of treatment includes loss of appetite, nausea, vomiting, abdominal pain, diarrhea or constipation or diarrhea alternating with constipation and loss of weight or failure to gain weight The criterion of improvement is a marked decrease in the frequency as well as in the duration of the symptoms, or their complete amelioration, together with a decided gain in weight or at least a failure to lose weight In a number of instances the gastrointestinal improvement apparently exceeded the pulmonary improvement Improvement in the abdominal condition is characterized by diminution or absence of rigidity and lessening or disappearance of local tenderness Slight to moderate localized abdominal abnormalities may persist even after a marked gain in weight and a complete disappearance of symptoms X-ray evidence of lessened irritability of the bowel usually accompanies symptomatic improvement and diminution of physical signs This has been demonstrated in a number of instances by x-ray examination of the gastrointestinal tract six months or more after medical treatment has been instituted The proctoscope has been of value in two instances in which definite ulcers which could be seen in the lower portion of the bowel before treatment was begun had entirely healed after six months' medical treatment The blood picture failed to show any definite changes characteristic of improvement In fact, in every group there was a

<sup>22</sup> Bergen I A and Mary Victor Sister Diet in Intestinal Disorders I A M A 97: 151 (July 19) 1931

slight tendency for the red blood count to decrease during the six months or more of treatment

The cases studied for this report numbered 238. In reviewing table 3, we find that patients receiving calcium by mouth, intravenously or intramuscularly, with or without ultraviolet radiation, showed a more definite trend toward improvement than did groups 1-A and 1-B, who did not receive calcium. Calcium taken by mouth was as effective as that received intravenously or intramuscularly. The patients receiving calcium gluconate or calcium chloride plus ultraviolet radiation seemed to show a higher percentage of improvement than those on a diet, without calcium, plus radiation. Patients who did not receive ultraviolet radiation, groups 1-B, 2-B and 3-B, showed a lower percentage of improvement than the corresponding groups receiving radiation. Except in group 4-B, in which the improvement was practically equal to that in group 4-A, ultraviolet irradiation apparently decreased the

A high vitamin, smooth, high mineral diet is not as effective alone as with either ultraviolet irradiation or calcium therapy or as ultraviolet irradiation with calcium therapy.

Collapse therapy is an aid in the treatment of gastrointestinal tuberculosis, probably through the improvement in the pulmonary condition and the resulting decrease in the number of bacilli in the sputum.

Cleansing the mouth by chewing paraffin and expectorating for one half to three quarters of an hour after clearing the lungs by coughing is a practical measure in the prevention of intestinal tuberculosis as well as in its active treatment.

#### ABSTRACT OF DISCUSSION

DR DESCUM C. MCKENNEY, Buffalo. In the proctologic service of the Buffalo City Hospital there were 115 patients with pulmonary tuberculosis in various stages, and all with positive sputum were given a sigmoidoscopic examination regardless of intestinal symptoms, and in only four were ulcers found. As many of these patients had gastrointestinal symptoms, it shows that the sigmoidoscope is not of great value in making a diagnosis and also that lesions are situated higher up. In the treatment of gastrointestinal tuberculosis it is difficult to evaluate the worth of the different agents used. The authors have employed the well recognized treatment of high caloric, high vitamin and low residue diet and enhanced the treatment by adding calcium therapy, which they have found of still greater value with ultraviolet radiation. Dr Aitken of the Niagara Sanitarium believes that intestinal tuberculosis is practically always due to pulmonary tuberculosis with cavitation and has stated that since the use of collapse therapy in about 70 per cent of all his cases intestinal disease has been rare except in terminal cases, and that, when present, collapse therapy usually clears it up quickly. My experience parallels his. For acute painful conditions in the anorectal region, such as fissure and abscess, emergency surgery must at times be done. For the best results in less acute conditions, essential surgery should be postponed until the intestinal condition shows improvement, the criterion of which is pulmonary improvement. As in both these conditions there is an avitaminosis and demineralization, the authors' suggestion as to correction should improve surgical prognosis greatly. McConkey, in persistent diarrhea, gives intravenous calcium chloride until relief is obtained and also gives 2 Gm of bone phosphate four times daily to those who usually do not respond well to treatment when they cannot take a quart of milk daily. Intestinal tuberculosis begins in the ileocecal region, no doubt because of the narrowing of the bowel and resulting concentration of ingested tubercle bacilli. The authors' method of mouth cleansing should sidetrack the flow and be a valuable prophylactic measure. When the sputum becomes normal the intestinal condition improves.

DR HARRY GAUSS, Denver. As a preliminary to treatment it is important to decide just what is meant by "intestinal tuberculosis," because there exists a contradiction as to the incidence of this disease. There are, on the one hand, autopsy statistics from such excellent sources as Brown and Sampson, Schweigert, Schwatt and others, who state that from 50 to 80 per cent of those having pulmonary tuberculosis have intestinal tuberculosis. However, common clinical experience looks askance at these figures. At the Trudeau Sanatorium a careful study was made for the incidence of intestinal tuberculosis. In a study of some 1,800 patients with pulmonary tuberculosis they were able to demonstrate clinically intestinal tuberculosis in about 8 per cent of the patients. Yet from the same institution come autopsy statistics to prove that 50 or more per cent of those having pulmonary tuberculosis also have intestinal tuberculosis at the time of autopsy. It is evident that we are dealing with two different concepts, a pathologic and a clinical one. The pathologist is talking about anatomic alterations he finds at the autopsy table, which at times may be nothing more than terminal manifestations of the disease, whereas the clinician is talking about a symptom complex which produces morbidity and which he is

symptoms or at least kept them stationary in the larger percentage of cases with or without calcium therapy.

The pulmonary picture to some extent paralleled the gastrointestinal picture. If cases of improved and stationary pulmonary tuberculosis are combined, the number compares favorably with that for a combination of cases of improved and stationary gastrointestinal disease. Patients who received pulmonary collapse showed a relatively greater percentage of intestinal improvement than those who did not receive it. To sum up, of the entire series of 238 patients 163 showed gastrointestinal improvement. Of the improved group 134, or 82.3 per cent, had had collapse therapy. The disease was stationary in thirty-seven, of whom twenty-five, or 67.8 per cent, had had collapse therapy, while of the thirty-eight who were worse only nineteen, or 50 per cent, had had collapse therapy.

#### CONCLUSIONS

Calcium given by mouth, intravenously or intramuscularly appears to have definite therapeutic value in the treatment of intestinal tuberculosis. One method of administration has no particular preference over another.

Ultraviolet irradiation plus calcium therapy seems to have a slightly more beneficial effect than calcium therapy without irradiation.

called on to treat. In Denver we have set up criteria for the determination of intestinal tuberculosis. First, we observe that in adults it occurs usually in those having far advanced pulmonary tuberculosis. Some of the common signs and symptoms are diarrhea, cramps after eating, nausea, abdominal tenderness, pain over the colon and sometimes abdominal rigidity. Some of the x-ray manifestations are spastic filling defects of the ascending colon and increased irritability of the large bowel, and stasis of the small bowel. With the stasis goes segmentation and some dilatation, together with some gastric retention. However, all these signs and symptoms are merely manifestations of increased irritability of the colon and small bowel, and nothing more, and since many other conditions may produce manifestations of increased irritability, such as irritable colon, intestinal parasites and mucous colitis, it is necessary to exclude by careful differential diagnosis all the other things a patient may have, to make sure we are dealing with intestinal tuberculosis and not some other incidental digestive disturbance.

DR CLEMENT L. MARTIN, Chicago. The study just presented adds valuable data to the therapy of tuberculous enterocolitis. It is only by the comparison of this with similar studies that current therapy can be accurately evaluated. Of paramount importance is the question of diagnostic criteria. Agreement must be reached on what constitutes a sound basis for diagnosis. As to proctoscopic examination, it is of little consequence in this disease in institutional cases, diagnosis was made on the basis of the proctoscopic observations in only about 3 per cent of this series. Of course it is higher in the far advanced cases, being 25 per cent in one series of this particular group reported by me several years ago. In general, however, this examination is not particularly helpful in the diagnosis of institutional cases, in too many the disease is above the reach of the proctoscope. If ulcers are seen, it gives evidence of great value and then a direct diagnosis is generally possible. On the other hand, it is of great importance in the differential diagnosis of ulcers in the terminal bowel in ordinary practice. My own experience urges me to emphasize that, outside of institutions for the tuberculous, ulcers visible with the proctoscope are usually not tuberculous. If they are tuberculous, the pulmonary disease is nearly always so advanced and easily diagnosed by roentgenogram that mistakes should be rare.

DR MORRIS WEISSMAN, Chicago. Dr Gauss's suggestions concerning the diagnosis of intestinal tuberculosis are well taken, however, this paper covers treatment only. I should like to amplify a few points that were brought out. Not infrequently in the course of our study we were called on to decide whether a given toxic state was pulmonary or intestinal in origin. The final decision rested on repeated physical examinations over an extended period. Thus we were able to observe the current changes in the physical signs in either system. Quite often the two did not parallel. Not uncommonly the lungs would show improvement in the disease process while the intestine would simultaneously show progression, or vice versa. The more favorable intestinal course observed in the pulmonary collapse cases, while largely accounted for by the removal of a toxicity-generating focus and thus enhancing the defensive body mechanism, may also be due to the fact that those cases very likely are recruited from a class of people who have ample defense mechanisms to begin with, and thus the intestinal involvement is seldom of the fulminating type. In some cases, then, the improvement in the two conditions is merely parallel rather than interdependent. Concerning the general efficacy of the treatment as observed by us it may be stated that even in the cases in which a downgrade course proved inevitable, an amelioration of the distressing symptoms was generally noted. The study bearing on prophylaxis was based on the generally accepted belief that intestinal tuberculosis results from the repeated swallowing of sputum. Anything that would reduce the bacillary content of the sputum would thereby prove good prophylaxis. Paraffin showed the greatest reduction in the bacillary content and hence proved to be an ideal cleanser. There remains to be seen whether the feces will actually show a reduced bacillary content following repeated cleansing of the mouth by paraffin. Should it prove so, we may perhaps look toward a reduction in the incidence of intestinal tuberculosis by the use of paraffin as an oral cleansing agent.

## THE ERYTHROCYTE IN SICKLE CELL ANEMIA

MORPHOLOGY, SIZE, HEMOGLOBIN CONTENT,  
FRAGILITY AND SEDIMENTATION RATE

L. W. DIGGS, M.D.  
AND

JUANITA BIBB, A.B.

MEMPHIS, TENN.

In the rapidly expanding literature relating to sickle cell anemia, which now includes more than 140 articles there are numerous descriptions of erythrocytes, the most important of which are in the articles by Emmel,<sup>1</sup> Sydenstricker, Mulherin and Houseal,<sup>2</sup> Huck,<sup>3</sup> Hahn and Gillespie,<sup>4</sup> Hein, McCalla and Thorne,<sup>5</sup> Graham and McCarty,<sup>6</sup> Sharp and Schleicher,<sup>7</sup> and Vaubel.<sup>8</sup> In this paper we shall attempt to combine the observations of others with observations which we have made while studying forty-seven patients with active sickle cell anemia at the John Gaston Hospital in Memphis.

### MORPHOLOGY

When whole blood from a patient with sickle cell anemia is sealed under a cover slip and examined immediately, it is noted that most of the cells are round or oval and that there is a variable number of irregularly shaped cells and elongated and narrow cells with round or pointed ends. As the preparation stands for a period of hours, the carbon dioxide content of the drop increases, the cells expand and their capsules are placed under tension. The cells undergo a series of progressive transformations in shape and structure from round discoid forms to bizarre, multipointed forms (figs 1 and 2). This change may begin during the first hour after the blood is drawn, but as a rule the metamorphosis takes place at a maximal rate in from two to six hours and is usually complete within twelve to twenty-four hours. If the blood is rendered anoxic by placing a tourniquet around the arm or finger for five minutes or longer, the erythrocytes will undergo changes in shape faster than if venous or capillary blood is removed without stasis.<sup>9</sup>

If cells in a given microscopic field are watched during the transformation from one form to another, it is noted that the structural alteration proceeds in various ways. The most common manner of change, which has been well described by Emmel, Hahn and Gillespie and Vaubel, is pictured in figure 1. First there are a thickening of the cell on one side of the disk and a corresponding thinning out of the disk on the opposite

side The diameter of the cell becomes greater, and the margins of the thinned-out portion become scalloped and shortly afterward pointed. Coincidentally the thickened part of the cell becomes elongated and pointed filaments protrude from its ends and sides. In some cells the area of increased density appears in two places, and in occasional cells there are three foci of hemoglobin

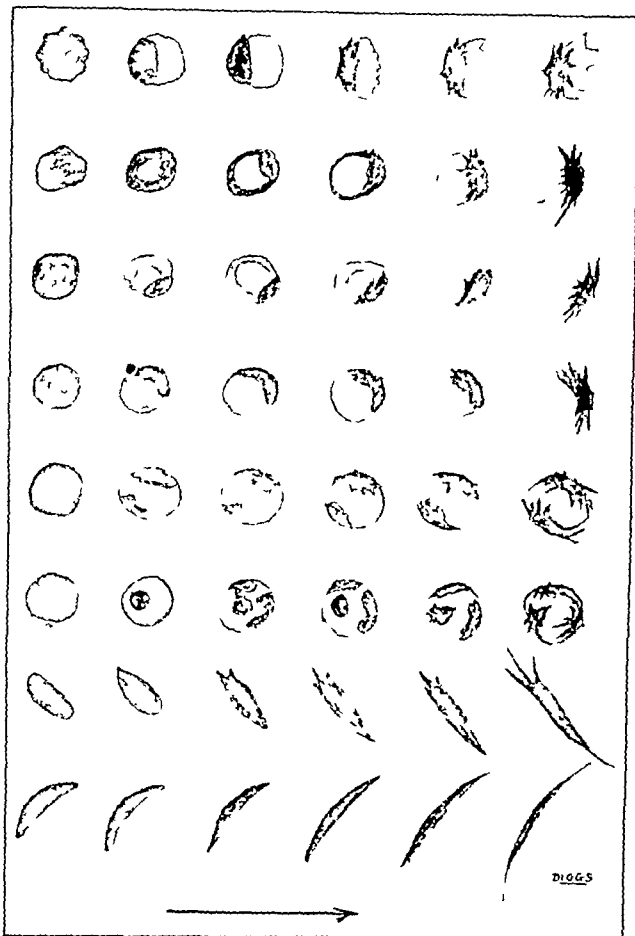

Fig 1—The sequence of morphologic changes in the erythrocytes in sealed moist preparations

condensation, each of which becomes pointed and separated from the others by a thin web of nonrefractive stroma (fig 1). The change from a round cell with even hemoglobin distribution to a many-pointed form, thick in one portion and thinned out like a fish fin in another, takes place within two to four minutes. After the cell has undergone this explosive sort of transformation, there are no further changes for many hours.

Some of the round and oval cells before changing their shape undergo active kneading movements for minutes or hours, rounded elevations appearing on their surface in one place and retractions of surface occurring at others. Finally sharp spicules appear, after which the movements cease as if the restrained forces within the cell had been released. In other cells there is no visible movement or shift in hemoglobin, but barbs of cytoplasm gradually protrude from the surface, giving a cocklebur effect and resembling exaggerated crenation. Graham and McCarty<sup>6</sup> described and illustrated a form of change in which practically all the cells have a needle-like form. We have observed this type of change in a few instances

but have never been fortunate enough to observe cells during their transformation from round to acicular types.

In all the forms of metamorphosis that we have observed, the points, filaments and sheets of cytoplasm that extend beyond the surface are mainly in the plane of the disk rather than perpendicular to its surface (fig 2). Occasionally cells in rouleau formation change their shape without changing their relationship to one another, and in this case the transformed group appears as a stack of needles.

Erythrocytes that are elliptic or of oat or crescent shape at the time the preparation is made do not undergo changes in shape similar to those described for round and oval cells. These cells have evidently already passed through the process, have lost their filaments and finlike appendages and have become irreparably changed in shape. In moist preparation, on standing, they merely protrude one or a few pointed filaments from their ends, or the points already present become longer (fig 1).

Cells which have undergone structural changes previously described (fig 2) are collectively called "sickled cells," although the term in a descriptive sense is inapplicable to any except the cells that are narrow, pointed and curved.

Fig 2—Erythrocytes in sealed moist preparations. Camera lucida drawings.

When blood in sealed moist preparations is exposed to the air by simply lifting the cover slip and immediately replacing it, the cells which have sickled in the bizarre manner will immediately revert to the round form. Oat and crescent shape cells on exposure to air become less pointed and may become elliptic but do not round up.

All the cells, regardless of shape, will become hemolyzed or will round up if left in the sealed moist preparation for days.<sup>5</sup> Some of the bizarre sickled forms will suddenly lose their hemoglobin and leave at the point where they formerly were a faintly visible ghostlike circle. Other cells undergo a slow degenerative change. The finlike appendages disappear, and

Fig 3—The sequence of morphologic changes in sickled erythrocytes on standing for days in sealed moist preparations

the pointed filaments become shorter and more blunt. Occasionally the filaments break off or little globules form along the filaments, which break off singly or in chains. Granules and vacuoles appear in the cytoplasm, the cells become more pale and the margins less refractive, the diameters decrease and the cells become more spherical (fig 3). Ultimately there is nothing left but amorphous debris.

Cells in moist preparation stained with dyes such as vital red, brilliant cresyl blue and methylene blue show structural transformations similar to those found in unstained preparations.<sup>10</sup> Cells containing reticulum do not sickle as readily or in as bizarre a form as do the more mature cells. Nucleated red blood cells undergo changes in shape even less readily, but they do sickle. The erythrocytes in blood mixed with oxalate, citrate or saline solutions likewise undergo the same type of changes, but if the blood is diluted much the process takes place more slowly or not at all.

Erythrocytes placed in a saline citrate solution in a test tube, sealed with liquid petrolatum and allowed to stand will undergo changes similar to those just described. In order to prevent the cells from rounding up on exposure to air, solution of formaldehyde is added before examination.<sup>11</sup> Red cells exposed to

carbon dioxide in hanging drop preparations or in test tubes undergo similar structural changes.

The erythrocytes in the stained smears of blood from patients with sickle cell anemia resemble those found in moist preparations immediately after the preparation is made (fig 4). Fish fin and multipointed shapes, which are characteristic of the moist preparations after standing, are not seen in their complete form in stained smears, but semblances of these forms can be found on searching. This indicates that at least some of the cells were sickled in the circulating blood and when smeared became fixed by drying before they had a chance to round up completely.

The type of cell which is most characteristic of sickle cell anemia and which is rarely observed in any other condition is the hyperchromatic, elongated form, pointed at each end and curved in the middle (fig 4). These cells may be as long as 50 microns and as narrow as 1 or 2 microns, but the majority are from 10 to 20 microns long and from 2 to 4 microns in their widest diameter. In some smears the sickled cells show degenerative changes in the form of vacuoles or granules and irregularities of margin of the moth-eaten type. Small bacillus-like rods of hemoglobin are found in the smears, which are evidently broken-off bits of cytoplasm from the elongated filaments.

The number of typically sickled forms in stained smears is highly variable with different patients. In numerous patients there are no forms sufficiently typical to warrant the diagnosis of sickle cell anemia.

Fig 4—The shape and relative size of erythrocytes in stained smears

from the structure of cells alone. Elliptic and oat shape cells are more numerous in the stained smears than are cells shaped like a sickle, but these forms may likewise be few. There is no sharp line of demarcation between the round, the oval, the blunt elliptic, the elongated elliptic, the elongated with one and with two points and the curved cells with double points

<sup>10</sup> Hansen Pruss O C J Lab & Clin Med 22 311 315 (Dec.) 1936

<sup>11</sup> Beck J S P and Hertz C S Am J Clin. Path 5 325 332 (July) 1935

(fig 4) It is a matter of opinion in counting the percentage of sickled cells, exactly how many there are. The percentage of sickled erythrocytes in cases recorded in the literature and our series is given in figure 5. We have had the opportunity of following a number of patients with sickle cell anemia at frequent intervals for a period of years and have observed that the percentage of double-pointed cells is fairly constant in a given person month after month. That this is not invariably true was shown in Emmel's case,<sup>1</sup> in which there were numerous sickled cells on one occasion and few on another. The percentage of sickled cells is not related to the severity of the anemia.

Haden<sup>12</sup> has recently called attention to a type of abnormality in which there is a central elevation, giving the appearance of a dot within a ring, to which he gave the name "Mexican hat." We have gone back over our slides and have without exception found this form in large numbers in smears from patients with sickle cell anemia. In some smears there are as many as ten or more of these forms to an oil immersion field, and in practically every field there are one or more cells of this type. We have on searching found similar cells in smears from patients with pernicious anemia, hemolytic jaundice, erythroblastic anemia and leukemia but have not observed this form in normal blood. It is possible that this abnormal area of increased density is related in some way to the sickle cell phenomenon and corresponds to the area of increased density seen in most preparations at the beginning of the sickling process.

The size of the round erythrocytes in sickle cell anemia is highly variable. Cells range in size from those as small as platelets to those as large as neutrophils. It is impossible to measure accurately the diameters of cells in smears from patients with sickle cell anemia in which there are many elliptic or oat and sickle shape cells, but with smears from patients with few cells of these forms Price-Jones curves can be made with a fair degree of accuracy. Haden<sup>12</sup> reported no significant abnormality in diameter of erythrocytes or in thickness

Fig 5—Frequency distribution curves according to the number of nucleated red blood cells per hundred white blood cells, the percentage of reticulocytes and the percentage of sickled red blood cells in stained smears.

of cells in two white patients with mild sickle cell anemia whose spleens had been removed. Wintrobe<sup>13</sup> reported the mean diameter of round cells in two cases of sickle cell anemia as 8.6 and 9.2 microns. Sharp and Schleicher<sup>7</sup> gave values for three cases as 8.6, 8.1 and 7.8 microns, respectively. The mean diameter was determined for ten of our patients in whose smears there were less than 5 per cent elongated cells. Thin dried smears made by the cover slip technique were used.

One thousand cells were measured in each case, an eye piece micrometer with graduations at intervals of 0.7 micron being used. The mean diameters were 7.8, 8.2, 8.4, 8.5, 8.5, 8.8, 8.9, 9, 9.5 and 9.5 microns. The average mean diameter was 8.7 microns. The average mean diameter of erythrocytes of five medical students used as controls was 7.6 microns. The frequency dis-

Fig 6—Erythrocyte diameters in sickle cell anemia (Price-Jones curves).

tribution curves of erythrocyte diameters and the composite curves for the ten patients with sickle cell anemia and the five controls are given in figure 6. From these observations it is obvious that there is in sickle cell anemia marked anisocytosis, and the average diameter is greater than normal.

Smears from patients with sickle cell anemia also show striking anisochromia. Diffusely basophilic cells are the rule. Howell-Jolly bodies and nuclear fragments of various types often are found. Stippled cells are seen sometimes and Cabot's rings rarely. Nucleated red blood cells with pyknotic nuclei and red-staining cytoplasm are demonstrable in practically all smears at all times, and occasionally the nucleated red blood cells are more numerous than the white blood cells. The frequency distribution of patients according to the number of nucleated red cells per hundred white cells in stained smears is given in figure 5. The number of immature red cells increases during the febrile sickness and decreases when the clinical symptoms subside. In occasional smears true megaloblasts are seen. Pointed and sickled nucleated red blood cells in various stages of maturity are sometimes found, which proves that the extrusion of the nucleus is not the explanation for the sickling phenomenon.

The percentage of reticulocytes is increased. In our series of forty-two cases in which reticulocyte counts were done, the average reticulocyte percentage was 15. We have seen reticulocyte counts as high as 87 per cent and have often observed counts above 25 per cent. The frequency distribution of patients according to reticulocyte count in our series and in the cases reported in the literature is given in figure 5.

In tissue preparations fixed in formaldehyde the erythrocytes are usually greatly elongated and oat shape, but curved, angular and bizarre forms are also

12 Haden R L and Evans F D. Sickle Cell Anemia in White Race. Improvement in Two Cases Following Splenectomy. Arch Int Med 60 133 142 (July) 1937.  
13 Wintrobe M M. Medicine 9 195 255 (May) 1930.

seen The sickling is less striking in tissues fixed in Zenker's solution A good way to demonstrate the presence or absence of sickling in tissue preparations is to grind up bits of tissue in a mortar and examine drops of this material microscopically The sickling is demonstrable in all tissues but is most marked in sections from the spleen or bone marrow The smaller blood vessels appear to be distended by sickled cells, and it is possible that the abnormal shape of the cells and their great length interferes with the free circulation of blood and is a factor in the production of thrombosis, which is a common feature of this disease<sup>14</sup>

Erythrocytes of the double-pointed type have been observed in the urine, cerebrospinal fluid and fluids from the serous cavities We have also observed three patients with sicklemia who had no true sickled forms in the stained smears of their blood, yet who had in their pleural or ascitic fluid typical sickled cells which would not round up on exposure to air Evidently these cells, under the conditions of anoxemia in a body cavity, had undergone the bizarre type of change, had lost their finlike appendages and multiple points and had become irrevocably sickled This together with the morphologic evidence is fairly reliable proof that the sickled cells in the stained smears of sickle cell anemia were first bizarre in shape and that the true sickled cell is a degenerative form

MEAN CORPUSCULAR VALUES

The mean corpuscular values reported in the literature are few, and the statements made concerning the mean corpuscular volume, mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration are not in agreement We determined the red cell count, hemoglobin content and volume of packed red blood cells of thirty-eight patients with sickle cell

Fig 7—Mean corpuscular values in forty four cases The position of the mean is indicated by the white line

anemia The total number of determinations was 100 When more than one determination was made on the same patient, the average values were taken as representative Pipets and counting chambers certified by the United States Bureau of Standards were used The hemoglobin content was determined by the acid hematin method, with instruments standardized each quarter by the oxygen capacity method of Van Slyke

14 Diggs I W and Chung R E South M J 27 939 845 (Oct.) 1934

The determinations of cell volume were made by mixing 10 cc of venous blood with 20 mg of dried potassium oxalate and centrifuging in a 15 cc graduated centrifuge tube in a size 2 international centrifuge until there was a constant pack The factor 1.09 was used to correct for shrinkage due to the dried oxalate

The frequency distribution of mean corpuscular values for thirty-eight cases of sickle cell anemia in our

Fig 8—Fragility of erythrocytes in hypotonic solutions in fifteen cases of sickle cell anemia and in seven cases of sicklemia.

series and for six cases reported in the literature are given in figure 7 The average mean corpuscular volume in the forty-four cases was 90 cubic microns, the average mean corpuscular hemoglobin 29 micrograms and the average mean corpuscular hemoglobin concentration 32 per cent

Reliable standards for Negroes are not available, but we have found for a small number of healthy Negroes employed in the hospital values comparable to those for white persons In a control series of determinations made on forty white male medical students by Dr R M Moore in this clinic with our instruments and methods, the average mean corpuscular volume was found to be 86 cubic microns, the average mean corpuscular hemoglobin 29 micromicrograms and the average mean corpuscular hemoglobin concentration 33 per cent These figures are essentially the same as those reported by Wintrobe<sup>15</sup> From these observations the conclusion is drawn that the erythrocytes in sickle cell anemia are usually of the normocytic, normochromic type, with a tendency toward macrocytosis

There was no apparent correlation between the mean corpuscular volume, the mean corpuscular hemoglobin or the mean corpuscular concentration and the reticulocyte count, the number of nucleated red blood cells, the percentage of cells sickled in stained smears, the severity of the anemia or the mean cell diameter

FRAGILITY TESTS

The erythrocytes in sickle cell anemia are more resistant than are normal cells to hypotonic saline solutions The reported fragility tests showed a few instances of normal or of decreased resistance, but the fifty-two reports available in the literature showed that, on an average, hemolysis began in a 0.38 per cent solution of sodium chloride and was complete in a 0.28 per cent solution The results obtained when the fragility

15 Wintrobe M M J Lab & Clin Med 17 899 912 (June) 1932

of the erythrocytes was tested in fifteen of our cases are given in figure 8. In these cases the average values were 0.34 and 0.11 per cent, as compared with 0.42 and 0.32 per cent for the controls. We have confirmed the observation of others that some of the erythrocytes in some of the patients with sickle cell anemia will retain their hemoglobin in distilled water. The increased resistance of the erythrocytes in sickle cell anemia to hypotonic saline solutions is probably explainable by the ability of these cells to alter their shape without placing their membranes under sufficient tension to cause hemolysis.

The fragility of erythrocytes in association with the sickle cell trait in the absence of anemia has been determined in few instances. Cooley and Lee<sup>16</sup> reported no difference in the fragility of the erythrocytes of children with and without the trait. Graham and McCarty,<sup>9</sup> on the other hand, stated that "in a series of 24 meniscocytic bloods we found an average range of hemolysis from 0.39 to 0.19 per cent NaCl and concluded that the resistance was definitely increased." We determined the resistance of the erythrocytes to hypotonic solution in seven cases of sickle cell anemia, using as our end point for complete hemolysis the level at which no cells containing hemoglobin appeared in the sediment on microscopic examination (fig. 8). The average values for this series were 0.35 and 0.2 per cent, whereas in the control group they were 0.39 and 0.27 per cent.

In order to test the resistance to mechanical trauma of the erythrocytes in sickle cell anemia, a hinged board was attached to the shaking device on a manometric Van Slyke machine. Glass tubes containing the oxalated or defibrinated blood to be tested were attached to this board and shaken at the rate of 250 vibrations per minute. It was found that this type of trauma over

*Resistance of Erythrocytes in Sickle Cell Anemia*

Experiment	Hours of Shaking	Percentage of Erythrocytes Destroyed	
		Patients with Sickle Cell Anemia	Controls
L O & L W D	6	62	44
A M C & J B H	8	68	44
L O & A L	7	47	30

a period of hours was not sufficient to cause an appreciable difference in the red cell count or in the cell volume in blood from normal persons or from patients with sickle cell anemia. However, by adding fifty glass beads to each tube and passing carbon dioxide gas continuously through the column of gas above the blood during the process of shaking, the cells were destroyed in appreciable quantities. The carbon dioxide served the dual purpose of making the cells larger and therefore more fragile and of causing the round cells in the blood of sickle cell anemia to become sickled. In three experiments performed under these conditions the cells were destroyed more rapidly in the blood from patients with sickle cell anemia than in that from the controls, as shown in the accompanying table. Determinations of cell volume during the shaking experiments showed values comparable to the red cell counts. Microscopic examination of the specimens of blood containing the sickled erythrocytes revealed more fragments and cellular debris than did microscopic examination of normal blood.

#### SEDIMENTATION RATE

Little information is to be obtained from the literature concerning the sedimentation velocity of erythrocytes in sickle cell anemia. The sedimentation rate was determined for twenty-three of the patients in our series. The total number of determinations was forty-nine. Oxalated blood and 5 cc Cutler tubes were used; the readings were made at five minute intervals for one hour. In four instances the sedimentation rate was 5 mm or less in one hour, and in fourteen instances the rate was less than 10 mm in one hour. Repeated examinations of the sedimentation rate for the same person at different times revealed variable rates, although the degree of anemia did not significantly change. Increased rates could usually be explained by some demonstrable abnormality, such as active tuberculosis, salpingitis or badly infected ulcers of the legs, but in some cases there was no obvious cause for the increased rate. The fact that the sedimentation rate may be normal in spite of severe anemia indicates that the increased rate in these cases is due to some complication, whether it is clinically demonstrable or not. Since the sedimentation rate may be normal in the presence of marked anemia, it is obvious that correction factors based on the degree of anemia are not applicable in this disease.

#### ABSTRACT OF DISCUSSION

DR EDWIN E. OSGOOD, Portland, Ore. The authors have probably given the best summary of the status of the erythrocyte in sickle cell anemia to date. Their study demonstrates that the disease is a normocytic anemia, as the few cases which I have had an opportunity to study in the North seemed to indicate. I should like to ask how they differentiate anemia due to other causes in a Negro with the sickle cell trait from true sickle cell anemia. They have shown that the sickle cell trait is common in Negroes, and it would seem that if such a Negro had anemia of another cause the problem of differential diagnosis would be more difficult. The authors did not have time to stress the differences between ovalocytosis, or familial poikilocytosis, as I prefer to call it, and the true sickle cell phenomenon. Familial poikilocytosis occurs just as commonly in white persons as in Negroes but has no association except an accidental one with anemia. It is relatively common, and the cells may superficially resemble sickle cells in Wright's stain. However, in Wright's stain they are really sausage shaped and the ends are rounded rather than sharply pointed, as so well illustrated for sickle cells. The number of poikilocytes does not increase in familial poikilocytosis in an atmosphere of carbon dioxide or on standing in a moist cover slip preparation as does the number of sickle cells. Dr Warren C. Hunter of the University of Oregon Medical School has studied a considerable family showing familial poikilocytosis, one of whom had anemia due to sinus infection. If these criteria are kept in mind, the differentiation should offer no difficulty.

DR L. W. DIGGS, Memphis, Tenn. The blood smear of sickle cell anemia in which there are few sickled cells may resemble that of other types of hemolytic anemia or secondary anemia, but there are numerous points of differentiation. In the first place one can usually find, on searching, typical oat and crescent forms, which are rarely observed in other blood dyscrasias. The white blood cell count is increased, and there are thrombocytosis and evidence of abnormal regeneration of the bone marrow. The reticulocytes are increased. The erythrocytes are more resistant to hypotonic salt solutions than are normal cells. There is jaundice of a retention type with a negative reaction to the direct van den Bergh test and urobilinuria. The history of chronic anemia and of recurrent febrile illnesses with severe pains anywhere in the body, usually in the joints, bones or abdomen, is fairly characteristic. Important physical characteristics are jaundice, cardiac enlarge-

<sup>16</sup> Cooley, T. B. and Lee, Pearl. Sickle Cell Phenomenon. *Am J Dis Child* 32: 334-340 (Sept.) 1926.

ment, hepatomegaly and ulcers of the legs. In the early stages the spleen is enlarged, but later there is splenic atrophy. As a rule, patients with sickle cell anemia are tall and slender, with long extremities. In some cases roentgenograms reveal a thickening of the skull, with perpendicular striations and patchy osteoporotic and osteosclerotic changes in the long bones. The clinical symptoms and signs together with the laboratory data constitute a definite syndrome, yet sickle cell anemia is often mistaken for other conditions. In practice, sickle cell anemia is not confused with other types of anemia but with acute febrile diseases, such as rheumatic fever, acute arthritis, osteomyelitis, appendicitis, pericarditis, catarrhal jaundice, meningitis and typhoid. In the presence of the sickle cell trait without anemia the erythrocytes appear to be normal in the stained smears, but in moist preparations they assume multipointed and finlike forms. With the elliptic cell trait (ovalocytosis) the erythrocytes are elliptic in the stained smears and do not undergo changes in shape in moist preparations. Pollock and Dameshek and also Cardozo have recently described a third type of abnormality characterized by the presence of elliptic cells which in moist preparations protrude points from their ends and become oat shaped. This type of ovalocytosis closely resembles the sickle cell trait but should not be confused with it.

## GASTROINTESTINAL SYMPTOMS IN DISEASE OF THE BRAIN

HARRY GAUSS, M.D.

DENVER

Gastrointestinal symptoms may arise from sources outside the digestive tract. They may arise from disease within the brain.

The interpretation of abdominal pain is a perennially interesting subject. The topic never grows old, nor can it be said that the subject has ever been fully analyzed and filed away in medical archives. Every new or improved diagnostic agent that is developed renders finer methods available for the interpretation of abdominal pain. Thus the electrocardiograph has helped to establish the fact that certain types of so-called acute indigestion, both fatal and otherwise, are actually coronary disease with referred abdominal pain. In a recent paper I<sup>1</sup> discussed the mechanism by which coronary disease causes acute abdominal pain.

The abdomen has been properly called the barometer or spokesman of the body. The abdomen calls attention to trouble but it does not locate it. The task remains for the physician, who must bear in mind that the responsible organ may be located anywhere in the body. The severity of the abdominal pain is no guide to the location of the causative agent. The most violent type of abdominal pain may arise from causes within the abdomen as in the case of biliary colic, or from causes outside the abdomen as in the case of referred pain from coronary disease. Likewise mild abdominal pain may arise from causes originating either within or outside the abdomen.

Elsewhere I have discussed some common causes of referred abdominal pain. I have pointed out that gastrointestinal symptoms may arise in the psychic apparatus,<sup>2</sup> in the pelvis<sup>3</sup> or in the renal system,<sup>4</sup> as

well as in the cardiovascular system.<sup>1</sup> It is my purpose in this paper to discuss the brain as a source of gastrointestinal symptoms.

My attention was directed to the brain as a cause of digestive disturbances by a patient who manifested vague gastrointestinal symptoms suggestive of gallbladder dyspepsia for a number of months and who subsequently was found to have a pituitary tumor.

**CASE 1—Gallbladder dyspepsia syndrome from pituitary tumor with recovery.** I. S., a man aged 39, who came under observation March 6, 1934, complained of abdominal pain, fullness after meals, bloating and belching, accompanied by a sensation of oppression in the epigastrium. These attacks were precipitated by the eating of fried foods, greasy foods, eggs, smoked meats, coffee and some other foods. At times he experienced sinking spells in the abdomen and general weakness.

The patient was well nourished, weighed 154 pounds (70 Kg.), and was 5 feet 7 inches (170 cm.) tall. His pulse rate was 80, the temperature 97 F., the respiratory rate 14 and the blood pressure 110 systolic, 60 diastolic. The eyes reacted to light and in accommodation. The throat was clear and the tonsils were out. The heart and lungs were normal. In the abdomen the pain was indicated along the costal margin. The liver and spleen were not palpable.

The urine and blood were normal. Analysis with the Ewald test meal showed an absence of free acid and a combined acidity of 12.

X-ray examination of the stomach and intestine revealed nothing unusual about these organs, the gallbladder, however, was poorly visualized and filled and emptied slowly.

A diagnosis was made of gallbladder dyspepsia and achylia gastrica. Treatment for these conditions was prescribed. However, the patient did not improve. On the contrary, he became worse. Three months later, violent headaches and impaired vision developed. An x-ray examination of the skull showed an erosion of the sella turcica, which suggested the presence of a pituitary tumor. An intracapsular enucleation with resection of the capsule of the pituitary tumor was carried out by Dr. A. W. Adson of Rochester, Minn. The microscopic diagnosis of the removed tumor was chromophobe adenoma.

Subsequently the patient had a protracted convalescence with a gradual return of vision of both eyes. The gastrointestinal symptoms subsided after the operation and have not returned. Eighteen months later the patient was able to resume part of his work, and he has since been free from the digestive disturbances.

Stimulated by this experience I made a study of some histories at the Colorado General Hospital of patients with brain tumor who presented gastrointestinal symptoms. In this study I was aided by Drs. J. R. Jaeger and Abe Ravin. These nineteen histories, with the one just given, are presented in condensed form in the accompanying table. Most of the patients entered the hospital in the stage of advanced brain tumor formation, when the neurologic signs and symptoms overshadow the gastrointestinal symptoms, nevertheless the digestive symptoms were noted. However, it is in the early stage of brain disease that the presenting symptoms are apt to be largely digestive. It is at this time that the possible relation of the digestive syndrome to the brain should be kept in mind if an early diagnosis is to be arrived at.

A study of my cases as well as of the literature indicates that certain diseases of the brain are apt to produce digestive disturbances. These are brain tumor, other expanding intracranial lesions, syphilis, epilepsy and migraine. These lesions of the brain produce three types of gastrointestinal syndromes: (1) the dyspepsia syndrome, with nausea, vomiting and abdominal pain, (2) the acute paroxysmal attack which occurs in epi-

From the Department of Medicine, University of Colorado. Read before the Section on Gastro-Enterology and Proctology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

lepsy, migraine and syphilis and (3) the syndrome of peptic ulcer and other erosions of the upper part of the intestine

#### DYSPEPSIA SYNDROME

Dyspepsia occurs in some instances of brain tumor and other expanding intracranial lesions. The word dyspepsia is employed here in a broad sense to designate a variety of symptoms commonly encountered in

Fig 1—Normal skull of an adult showing an average occipitofrontal diameter, the well defined sella turcica, the usual suture and blood vessel markings and the customary density of the cranial bones. (The roentgenograms and their interpretation were made by Dr. F. A. Schmidt of the University of Colorado.)

patients presenting the abdominal distress syndrome. The following symptoms have been observed: abdominal pain, abdominal consciousness, nausea, vomiting, loss of appetite, morbid hunger, capricious appetite and a dislike for certain foods. In the early stages of brain tumor the patient may present a syndrome strongly suggestive of gallbladder dyspepsia or food allergy. Patient 1 stated that his abdominal distress was aggravated by the eating of fried foods, eggs, smoked meats and coffee.

Nausea and vomiting occur in many cases. They were the commonest of the digestive symptoms in my series. Jaeger<sup>6</sup> has observed that persistent vomiting may be the only indication of an intracranial lesion in the early stage. Disturbances of the appetite may present bizarre pictures. The appetite may be increased, diminished or capricious. Spiller<sup>7</sup> recorded a case of glioma of the pons in which intense hunger was a prominent symptom. Watts<sup>8</sup> described a man with a tumor of the right frontal lobe which began with the sudden appearance of a ravenous appetite. Patient 2 exhibited a capricious appetite. On arising he experienced "morning sickness." He could eat nothing before 10 a. m., when his appetite returned, after which he became ravenously hungry. He died of cerebellar medulloblastoma.

Abdominal pain occurs in some cases and may manifest itself as epigastric distress, pain in the right upper quadrant, diffuse abdominal cramps or a dull umbilical

pain. The pain is commonly recurrent but may be constant and may have no relation to the gastric cycle.

Recently Wechsler<sup>8</sup> reported a series of fourteen cases of disease of the brain in which abdominal pain was one of the presenting symptoms. The pain was often cramping, it involved all portions of the abdomen, sometimes it was associated with nausea and vomiting and it occurred without any relation to the gastric cycle.

These symptoms of dyspepsia which occur in disease of the brain raise the question whether it is possible for intracranial lesions to affect the gastrointestinal tract and so produce the symptoms of abdominal distress.

Wechsler expressed agreement with Watts and Fulton<sup>9</sup> that the irritation of the autonomic representation in the brain points to the probable explanation of the abdominal distress that occurs in disease of the brain and that most evidence points to the premotor area of the cortex, the hypothalamus and the vagus as the regions responsible for abdominal pain. The abdominal pain, however, is mediated by way of lower levels or centers, hence, while abdominal distress does occur in disease of the brain, it has no localizing value diagnostically.

#### PAROXYSMAL ATTACKS

Paroxysmal disturbances of the abdomen are apt to occur in epilepsy, migraine and syphilis.

In epilepsy the abdominal attack occurs during the aura, after the convulsive attack or as an equivalent of the convulsion itself. In so-called abdominal migraine the digestive disturbance occurs as an equivalent of the headache. In neurosyphilis sudden attacks of violent pain occur in the upper part of the abdomen, the so-called gastric crises.

Fig 2 (case 1)—Increase in the occipitofrontal diameter, flattening and enlargement of the sella turcica and erosion of the posterior clinoid process.

During the visceral type of epileptic aura, gastrointestinal symptoms occur commonly. Epigastric distress occurs as a painful burning sensation, sometimes there are peristaltic unrest, nausea, vomiting, cramp, salivation, dryness of the mouth, intense thirst and urge to defecate. During the convulsion involuntary

defecation may occur, while at other times abdominal distress may occur as an equivalent of the convulsion itself

The work of Penfield and Gage,<sup>10</sup> of Sherrington<sup>11</sup> and of Watts and Fulton suggests that there is a sensory autonomic representation for the gastrointestinal tract in the cerebral cortex, which accounts for

There are numerous theories to explain migraine. Recently the allergic basis has been strongly advanced. Some writers, however, agree with Critchley and Ferguson<sup>13</sup> that the case for the allergic nature of migraine has been overstated.

Bassoe<sup>14</sup> has pointed out that, just as in epilepsy gastrointestinal symptoms may become the equivalent

Summary of Twenty Cases of Brain Tumor Presenting Gastrointestinal Symptoms\*

Case	Patient	Sex	Age Years	Lesion	Neurologic Symptoms	Gastrointestinal Symptoms	Condition on Discharge
1	I S	♂	39	Chromophobe adenoma of pituitary body	Bilateral hemianopia pallor of disks headache impaired vision	Abdominal pain fullness after meals bloating belching, dislike for certain foods	Improved
2	I B	♂	15	Medulloblastoma of cerebellum	Impaired vision, tremor of left arm exaggerated reflexes bilateral papilledema, nystagmus	Loss of appetite in morning morning sickness nausea, vomiting, polyphagia in afternoon	Died
3	M P	♂	42	Glioma of right frontal lobe	Impaired vision headache loss of memory muscular tremors choked disks	Loss of appetite nonprojectile vomiting, nausea cramps	Died
4	J O	♀	6	Glioma of medulla	Internal strabismus headache nystagmus loss of hearing ataxia facial paralysis on the left side	Projectile vomiting cramps	Improved
5	S B	♂	48	Tumor of right frontal lobe	Muscular weakness dizziness headache loss of memory ataxia papilledema tingling of fingers	Projectile vomiting nausea epigastric distress	Unimproved
6	J W	♀	37	Meningioma on left side	Headache impaired vision ataxia vertigo loss of hearing nystagmus exaggerated reflexes	Nonprojectile vomiting bloating symptoms accentuated by eating epigastric distress	Died
7	M B	♀	11	Astrocytoma of cerebellum	Choked disks ataxia muscular weakness headache convulsions impaired vision	Nonprojectile vomiting, nausea abdominal cramps	Improved
8	N A	♀	7	Glioma of cerebellum	Headache weakness of left arm ataxia	Nonprojectile vomiting foul breath constipation cramps	Unimproved
9	P P	♀	7	Glioma of medulla	Nystagmus, exophthalmos ataxia bilateral papilledema headache	Nonprojectile vomiting nausea loss of appetite abdominal pain cramps	Unimproved
10	D O	♂	4	Cerebellar tumor	Headache convulsions inability to walk ankle clonus nystagmus	Nonprojectile vomiting loss of appetite constipation	Unimproved
11	J J	♀	1½	Ependymoma of cerebellum	Choked disks ataxia exaggerated reflexes retarded growth	Constipation foul breath distention	Died
12	R H	♂	10	Cerebellar tumor	Loss of vision, ataxia internal strabismus headache dizziness	Nonprojectile vomiting cramps abdominal pain	Died
13	W B	♂	38	Tumor of third ventricle	Choked disks ataxia vertigo convulsions headache	Nausea vomiting abdominal cramps	Died
14	P H	♀	30	Glioma of pons	Headache tremor on right side ataxia dizziness impaired hearing nystagmus	Projectile vomiting anorexia epigastric distress	Died
15	L L	♂	34	Infundibular ependymoma	Impaired vision dizziness headache pain and cramps in legs	Nonprojectile vomiting nausea constipation abdominal distress	Died
16	S W	♀	43	Oligodendroglioma of left frontal lobe	Convulsions headache weakness impaired vision confused state	Projectile vomiting nausea abdominal distress anorexia	Improved

18	M W	♂	72	Glioma of right frontal lobe	Tremor of left hand and leg bilateral papilledema ataxia headache weakness loss of memory	Projectile vomiting pain in upper part of abdomen	Improved
19	A L	♂	53	Tumor of left frontal lobe	Headache falling vision vertigo confused state ataxia bilateral papilledema	Loss of appetite gaseous eructations nausea vomiting epigastric fullness bloating	Unimproved
20	A H	♀	33	Meningioma on left side	Convulsions involving right side headache loss of memory confused state bilateral papilledema	Epigastric sensory aura preceding convulsions	Improved

\* A craniotomy with attempted resection of the tumor was performed in all cases except 5 and 17

the abdominal pain and other symptoms that occur in epilepsy of cerebral origin

Migraine has been described by Riley<sup>12</sup> as a periodic incapacitating headache culminating in nausea and vomiting, often preceded by visual disturbances followed by sleep and occurring against a background of relatively perfect health

of the convulsive seizure, in migraine paroxysms of abdominal pain may be substituted for headache

In abdominal migraine the abdominal pain may become so acute and sharply localized that it simulates acute abdominal disease calling for surgical intervention. Many futile operations have been performed because of the acuteness of the abdominal pain and of the impressions of the existence of so-called acute surgical abdomen

Blitzsten and Brams<sup>15</sup> reported a series of thirty-two surgical cases in which it was later shown that the abdominal pain was an expression of abdominal migraine. Similar reports have been made by Woltman,<sup>16</sup> by Bassoe and by Pollock and Barborka.<sup>17</sup>

Migraine, like epilepsy, is considered by many writers to be an expression of fleeting cerebral pathologic changes and the abdominal pain as resulting from local changes in the brain.

Perhaps of all the cerebral lesions which produce paroxysmal abdominal pain the gastric crisis of neurosyphilis is the best understood. The patient experiences a sudden attack of violent pain in the upper part of the abdomen. The pain radiates in all directions. Commonly it is associated with nausea, vomiting and severe prostration. The attack is variable in duration, lasting from hours to days, and it disappears as suddenly as it came, only to reappear later.

#### PEPTIC ULCER AND EROSIONS

According to Cushing<sup>18</sup> and others, a relation seems to exist between tumors of the brain, peptic ulcer and other perforations of the upper part of the intestine.

Harvey Cushing has given emphasis to this neurogenic theory of peptic ulcer. He demonstrated that a clinical and experimental relation exists between disease of the interbrain and ulcers of the upper part of the alimentary canal. His attention was directed to the neurogenic relation by the disturbing experience of having three patients die from perforation of the upper part of the intestine soon after what appeared to be a successful operation for the removal of an intracranial tumor. He observed eight other patients in whom

and Brown<sup>21</sup> Cushing's views on the neurogenic basis of peptic ulcer are by no means universally accepted. However, the association between tumors of the hypothalamus or its pathways, as well as experimentally produced lesions of the diencephalon, and hemorrhagic ulcers and perforation of the upper part of the intestine cannot be ignored.

Fig. 4 (case 13).—Ventriculogram showing a marked enlargement of the lateral ventricles of the brain as well as of the third ventricle indicative of an internal hydrocephalus. The cranial bones present the beaten silver appearance.

Fig. 3 (case 9).—Enlargement of the occipitofrontal diameter widening of the suture lines and accentuation of the impressioes digitatae or beaten silver appearance of the cranial bones. These signs are considered to be indicative of intracranial pressure. The sella turcica is normal.

intracranial lesions were found to be associated with gastric ulcers. Similar observations have been reported by Grant,<sup>19</sup> by Masten and Bunts<sup>20</sup> and by Vanzant

#### SUMMARY

1. Gastrointestinal symptoms may arise from sources outside the digestive tract.
2. They may arise from disease within the brain.
3. Gastrointestinal symptoms are apt to occur with tumors of the brain, other expanding types of intracranial lesions, epilepsy, migraine and syphilis.
4. Three gastrointestinal syndromes are apt to be produced by the intracranial lesions: (1) the chronic dyspepsia syndrome, (2) the acute paroxysmal attack and (3) the peptic ulcer syndrome.
5. The chronic dyspepsia syndrome includes abdominal distress, nausea, vomiting, and changes in the appetite. This occurs most frequently in association with brain tumors.
6. The acute paroxysmal attack is manifested by sensory and motor disturbances. It occurs in cases of epilepsy, migraine and syphilis.
7. Peptic ulcer and other erosions of the upper part of the intestine occur with tumors and other expanding intracranial lesions.
8. There are no pathognomonic abdominal signs or symptoms of intracranial origin.
9. The following symptoms, however, if otherwise unaccounted for, should suggest the possibility of a lesion in the brain: persistent vomiting, projectile vomiting, bizarre disturbances of the appetite, abdominal distress with or without nausea and vomiting without relation to the gastric cycle.
10. A study of the literature seems to indicate that there is present in the cortex a motor autonomic representation, both inhibitory and stimulating. The prob-

able course of this pathway is from the cortex to the hypothalamus, to the red nucleus, to the substantia nigra and to the vagus. Likewise there is present a sensory autonomic representation. Irritation of these pathways is believed to occur in cases of intracranial lesions, thus producing the symptoms.

11 The differential diagnosis between gastrointestinal disease and referred abdominal symptoms originating in disease of the brain is made from a careful consideration of both systems, aided by neurologic and x-ray examinations.

12 Although digestive symptoms may suggest the presence of an intracranial lesion, they are mediated by way of lower levels and hence have no localizing value.

13 There is no royal road to an easy differential diagnosis of acute abdominal pain.

Republic Building

#### ABSTRACT OF DISCUSSION

DR. EDWARD G. BILLINGS, Denver. Gastrointestinal syndromes often arise as a result of some extragastrointestinal disturbance. Disorders of the central nervous system must always be considered and therefore a neurologic study never omitted from the usual examination. However, if the physician stops here he will fail to elicit the true etiology in more than half the patients with symptoms referable to the alimentary system. In the medical clinic of the University of Colorado, in which all gastrointestinal complaint problems are examined, more than half of the patients, ranging in age from 12 to 50 years, with symptoms referable to the alimentary system have neither demonstrable gastrointestinal nor central nervous system disease. In these individuals the gastrointestinal system tends to participate more than the average in their emotional lives. As a result of the motility and secretory phenomena concomitant with the emotivity, symptoms and signs arise which are in truth but a type of "organ language" by which the personality protests to the stresses and strains of life. Nausea and vomiting are often the equivalents of disgust and aversion, anorexia and inappetence may be related to a disorder of mood, abdominal discomfort, ranging from the more vague and insignificant to the most acute and disturbing, is frequently the result of real gastrointestinal participation in such total personality reactions as tension, anxiety and fear. In these personality or psychogenically determined problems, attention to the patient's complete complaint, the setting in which it began, and its evolution in terms of personal and situational factors are the very foundation of the symptomatic, supportive, sublimatory and causal therapies, which in our experience have led to most gratifying results in terms of alleviating the gastrointestinal symptoms of these patients. Dr. Gauss has pointed out that gastrointestinal symptoms may be some of the protean expressions of disturbed functions of the central nervous system. Thus I strongly emphasize but in so doing wish to express that "the mere fact that a gastrointestinal disorder is carried on by neurogastrointestinal processes does not make that disorder nonmental."

DR. THEODORE L. ALTHAUSEN, San Francisco. It has often been said that there is no such specialty as gastroenterology, because a gastroenterologist has to be too well versed in diseases of the kidneys, the chest, and so on. This morning Dr. Bishop told us about the connection between cardiology and gastroenterology, and now Dr. Gauss is adding the study of neurology as a prerequisite for the practice of gastroenterology. To the three syndromes that Dr. Gauss mentioned I should like to add a fourth one, to which I called attention several years ago in the *American Journal of Digestive Diseases and Nutrition*, namely that of functional insufficiency of the liver in diseases of the central nervous system. An instance of gross pathologic changes involving the two organs is Wilson's disease, found chiefly among workers in manganese mines. In this disease there is cirrhosis of the liver associated with degeneration of the lenticular nuclei. In a series of 156 patients without clinical evidence of hepatic disease who were studied by means of liver function tests diseases of the central nervous system proved to be a significant source of potential error. It was

puzzling that the diseases of the central nervous system associated in patients with hepatic insufficiency were not of any one particular type. There were patients with tumors of the brain, with encephalitis, with multiple sclerosis, and others who unaccountably gave positive results with two or more liver function tests. Fernbach pointed out that patients with disorders of the central nervous system are often hypersensitive to insulin. This might invalidate liver function tests based on carbohydrate metabolism, however, it was found that dye excretion tests were equally affected by diseases of the central nervous system in these patients, so this isn't the whole explanation. Hess and Goldstein, Siedhoff, Richet, Jacquelin and Joly, and Crandall also found hepatic insufficiency, as evidenced by the results of several function tests, in various diseases of the nervous system.

#### EPIPHYSITIS OF THE CAPITELLUM OF THE HUMERUS

JOSEPH F. ELWARD, M.D.

WASHINGTON, D. C.

The pathologic process known as epiphysitis or osteochondritis is thus entitled because it involves primarily the articular extremities of bones and for the further reason that the epiphysis is frequently detached or destroyed during the progress of the disease. Osteochondritis and epiphysitis are practically identical, the age incidence of activity of the centers of ossification constituting the distinguishing factor. Accordingly, when the center of greatest activity is situated in the epiphysis, epiphysitis results and, when it is located in the centrum, osteochondritis occurs. Although characterized by a similar course in all the epiphyses, the disease manifests itself in each at the age period of

Fig. 1 (case 1)—Nov. 24, 1930

most rapid growth. Hence it has been described by certain writers as osteochondritis of the centers of growth or ossification. Proponents of the infectious theory of the still highly controversial etiology define epiphysitis as a form of acute osteomyelitis in which the focus of infection centers in the epiphyseal cartilage while it exists, and therefore as a malady most frequent in children and adolescents which it is in fact.

The earliest description of the condition properly classifiable as epiphysitis was that contributed in 1869 by Paul Vogt<sup>1</sup> on epiphysitis of the tibial tubercle, which was described both by Osgood<sup>2</sup> and by Schlatter<sup>3</sup> in 1903 and which has since been called Osgood-Schlatter's disease. König<sup>4</sup> in 1887 contributed a description

and by Calve<sup>7</sup> and Perthes<sup>8</sup> in turn in 1910, where upon it received the title of Legg-Calve-Perthes' disease. However, ever since Perthes' classic description in 1913 the disease which he finally denominated osteochondritis deformans juvenilis has been known generally by his name. Meanwhile, as Overton<sup>9</sup> said, Sever<sup>10</sup> had in 1912 contributed an original account of a related disease of the os calcis, which he called apophysitis.

In 1914 Freiberg<sup>11</sup> reported illustrative cases of a disease of the epiphysis of the head of the second metatarsal bone which he designated infraction, although it was later found that neither the anatomic examination nor the clinical evolution confirmed the radiographic appearance of fracture. Thereupon the more appropriate term of osteochondritis of the metatarsal heads, or metatarsal epiphysitis, was substituted. Thus, as Mouchet<sup>12</sup> remarked, the description by Freiberg ante

Fig 2 (case 1) —Feb 27 1931

of a condition marked by the appearance of free joint bodies, which resulted from pathologic compression fracture of dead epiphyses, with formation of a wall of bony debris which interfered with bony substitution and induced a process of delimitation, osteochondritis dissecans. In 1908 Kohler<sup>5</sup> published a description of the tarsal scaphoiditis which is now known by his name

Fig 4 (case 2) —April 24 1937

dated by six years that of Kohler relative to an identical disease of the metatarsals sometimes known as a second Kohler's disease.

Vertebral epiphysitis was first described by Scheuermann<sup>13</sup> in 1921 and osteochondritis of the vertebral body by Calve<sup>14</sup> in 1925. In the same year, Buchman<sup>15</sup> differentiated vertebral epiphysitis from tuberculosis of the spine, to which it bears a similar clinical aspect and from which it is distinguished chiefly by its immediate and favorable response to treatment.

In the foregoing brief historical survey, only the commoner and more familiar disorders of the epiph

Fig 3 (case 1) —June 1 1937

A peculiar disease of the hip with distinctive signs which served to differentiate it sharply from tuberculosis of the hip joint was reported first by Legg<sup>6</sup> in 1909.

uses have been considered. These are, in the approximate frequency of their occurrence, osteochondritis deformans juvenilis coxae, epiphysitis of the tibial tubercle, epiphysitis of the tarsal scaphoid, epiphysitis of the head of the second metatarsal bone, epiphysitis of the vertebra and osteochondritis dissecans.

However, while it may involve almost any bone, the disease occasionally is observed to appear in regions which seldom or never exhibit its characteristic lesions. Foremost among these usually exempted locations one may place the capitellum of the humerus. In fact, a meticulous search of the literature on the subject and

history were irrelevant. Anteroposterior and lateral roentgenograms (fig 1) showed increased subcortical radiability of the capitellum, indicating possible early inflammatory change. Another roentgenogram (fig 2), taken Feb 27, 1931, showed the capitellum markedly irregular and definitely fragmented. June 1, 1937, a roentgenogram (fig 3) showed the epiphysis solidly united with the diaphysis. There was no roentgenographic evidence of old or recent injury or disease. The patient had excellent dietetic and hygienic care from birth and received no specific treatment, since no radical change in his regimen was necessary. Use of the arm was allowed within the limit of comfort. The symptoms gradually subsided without complications or sequelae. The patient is now 15 years old.

extensive inquiry in person and by correspondence have elicited references to only four instances in which the capitellar epiphys of the humerus was affected.

The first of these cases was contributed by Panner<sup>16</sup> in 1927, Krebs also reported a case in 1927, and Smith<sup>17</sup> contributed a third case in 1928. I am indebted to Dr. Thomas A. Groover for the privilege of reporting the fourth case, hitherto unreported.

A boy aged 8 when first seen, Nov. 24, 1930 complained of slight pain and limitation of motion in the right elbow. There was no account of an injury. The family and the personal

To these unique cases is added a fifth, lately encountered in my own practice.

A boy aged 8, seen first April 24, 1937, had a history of a slight injury sustained several days previously. The chief complaint was pain in the left elbow with limitation of motion. A roentgenogram (fig 4) revealed an intact cortex and a marked increase in subcortical radiability. October 9 a second roentgenogram (fig 5) showed fragmentation, with a definite break in the continuity of the cortex. Roentgen study April 24, 1938 showed the capitellum markedly fragmented (fig 6). This patient has received no specific therapy, since his hygienic and dietetic regimen is satisfactory and no modifications have been deemed requisite.

The accompanying table is believed to be complete and gives the site of involvement, the name of the

physician who described or reported the case and the date. The use of proper names in connection with this condition is believed to be nonscientific and nondescriptive and serves no useful purpose.

1726 Eye Street, Northwest

#### ABSTRACT OF DISCUSSION

DR CARL H PARKER, Pasadena, Calif. I want to add one point to the discussion of this interesting condition. Recently I had the opportunity of studying an epiphysitis of the base of the first phalanx of the great toe. I found it in the acute stage, because the patient had stepped on a nail which penetrated the sole of the foot in that region and it was a question whether the condition was an infection or an epiphysitis. It proved to be an epiphysitis. In talking with

Fig 5 (case 2)—Oct 9 1937

the patient I found that she had had symptoms of Osgood-Schlatter disease. A roentgenogram of her knee showed typical Osgood-Schlatter disease on one side. Further study of the patient disclosed that she had an epiphysitis of the tuberosity of the ischium. The condition was bilateral. There were typical changes though the patient had been entirely without symptoms in this region. In these cases it may be

Fig 6 (case 2)—April 24 1938

worth while to make a survey to find instances of multiple epiphysitis, which are not often reported because many of them are symptomless.

DR JOHN PIERSON, Baltimore. Hypothyroidism is a condition which should always be considered in a discussion of the multiple bone lesions which have just been described. This disease frequently produces a granular appearance in one or more epiphyses, which changes may closely simulate those produced by epiphysitis or osteochondritis dissecans.

## PHYSIOLOGIC MOVEMENTS OF THE GASTROINTESTINAL TRACT

AS RECORDED BY THE ROENTGEN KYMOGRAPH

WENDELL G SCOTT, MD

BRUCE KENAMORE, MD

AND

J W LARIMORE, MD

ST LOUIS

Roentgen kymography has been accepted as a diagnostic method in the clinical study of heart disease. The procedure was later applied to the study of the peristaltic movements of the stomach, duodenum, small intestine and colon by Stumpf, Weber and Wetzl,<sup>1</sup> Schilling,<sup>1a</sup> Dahm<sup>2</sup> and Wetzl.<sup>3</sup> Our purpose in this paper is to report and in general to confirm their observations. In doing this we have borrowed freely from their publications and personal communications.

The principles and technic of roentgen kymography must be clearly understood in order to interpret the films, or kymograms, as they are called. The multiple slit kymograph is the achievement of Pleikart Stumpf, who introduced it in 1928<sup>4</sup> and perfected it by 1931.<sup>5</sup> The apparatus is relatively simple and commercially available (fig 1). The essential part is the grid, which is made of a large sheet of lead one-sixteenth inch thick. Narrow, horizontal slits are cut in the grid 12 mm apart. The opening in each slit is 0.35 mm wide. The patient stands with the abdomen against the grid during a single, continuous exposure of one minute for recording the movements of the stomach, thirty seconds for those of the duodenum and six minutes for those of the colon. During the exposure the x-ray film moves slowly down behind the fixed grid. It moves a distance slightly less than the space between two slits, actually 11.5 mm. By this method the movements, or changes in position, of multiple points on the border of the stomach or intestine are recorded simultaneously on the x-ray film as it is moving down behind the grid. The points on the stomach, the change in the position of which with peristalsis is recorded, are those which overlap the slits in the grid. Thus each frame (the space between two white lines on the kymogram) is the record of the excursion of one point at the edge of the stomach as it changes position during the passage of a peristaltic wave. The rapid movements of the stomach are recorded as horizontal or oblique lines, while slow movements are recorded as rounded curves. Areas without movement are recorded as straight perpendicular lines. The width of the slits, their space apart, the time of exposure, the movement of the film or grid and other technical factors vary among roentgenologists.

From the Edward Mallinckrodt Institute of Radiology, Washington University School of Medicine.

The time of occurrence of movements at different parts of the stomach, intestine or esophagus is readily determined, as all movements that are an equal distance above a white line at the bottom of a frame are recorded at the same instant. For a more detailed

Fig 1—Diagram of roentgen kymograph. The patient stands next to the grid and during a single continuous x-ray exposure of one minute for gastric films (thirty seconds for small intestine and six minutes for colon) the film slowly moves down behind the fixed grid a distance slightly less than the width between two slits. The roentgen kymograph records simultaneously the movements of multiple points on the border of the stomach. These points are the small areas on the gastric silhouette that overlie the slits. Thus the alterations in gastric form resulting from peristaltic activity are recorded in wave form. Each frame is then a record of the change in position of one of these small areas during the passage of a peristaltic wave.

description of the technique and principles of kymography, the reader is referred to the publications of Scott and his associates<sup>6</sup> and that of Hirsch.<sup>7</sup>

#### ESOPHAGUS

The movements of the esophagus have been studied most extensively by Dahm.<sup>8</sup> The esophagus is constantly moved by the transmitted pulsations from the heart and great vessels. These movements can be recorded in detail on a kymogram made while the patient swallows a contrast meal. By analyzing the shape and size of the imparted esophageal movements it is possible to determine the position of the great vessels and cardiac chambers that form the posterior portion of the cardiac silhouette. For example, that portion of the esophagus which is in contact with the aorta will have transmitted aortic movements registered over its border. That part of the esophagus immediately adjacent to the auricle will have auricular movements, and the lower portion, which is in contact with the ventricle, will exhibit ventricular movements. Such kymograms are called esophageal cardiograms.

In studying the peristaltic movements of the esophagus, Dahm<sup>8</sup> measured the speed of progression of peri-

staltic waves. He found that fluids descended more rapidly than a peristaltic wave could pass down the esophagus. A solid bolus of food was aided in its passage by the peristaltic movements. Pastes descended at the rate of about 13 cm in three minutes and peristaltic waves at about 5 cm in three minutes. Fluids descended at the rate of 156 cm in three minutes.<sup>1a</sup> The tonus of the esophagus determines the shape and form of the food bolus. The kymogram is ideal for recording the degree of tonus and peristaltic activity of the esophagus by an objective picture. For this reason it may be used to follow the improvement following treatment of cardiospasm and achalasia. It has been used to record the movements of swallowing and the antiperistaltic movements which occur in stenosis of the esophagus resulting from various causes.<sup>8</sup>

#### STOMACH

The peristaltic waves vary from person to person and in the same person at different times. They are influenced by the type and consistency of foods, by the state of health, by acidity and by psychic phenomena. As a rule the movements are the same under the same physiologic conditions. Because of the wide variations in the normal gastric movements, it is more difficult to recognize abnormal motion from the gastric kymogram than from the cardiac kymogram. It is a basic kymographic principle that only pathologic lesions that alter the physiologic movements of an organ or structure will record kymographic waves varying from the normal. The kymographic studies of the stomach should not be

Fig 2—Roentgen kymogram of a partially filled normal stomach to demonstrate the movements of the rugae. They are best visualized in frames 1 to 4. The rugae move at the same time and proceed in the same direction as those of the walls of the stomach. In this frontal projection the amplitude of rugae movement is least in the central portion of the stomach and most near the periphery. With the passage of a peristaltic wave the space between the folds of mucous membrane becomes less and the folds narrower. Only the large waves on the border of the stomach are peristaltic waves. The small serrations are the result of the respiratory movements of the diaphragm.

undertaken alone but should be part of the general roentgenologic investigation. The kymograms are simply a detailed photographic record of the movements transiently observed on the fluoroscopic screen.

8 Dahm Max. Zur Frage einer Antiperistaltik bei Stenosen der Speiseröhre. *Klin. Wchnschr* 17: 347-350 (March) 1938.

The stomach is loosely connected with its surroundings and is affected by extrinsic as well as powerful intrinsic movements. Stumpf<sup>9</sup> classified them as follows:

Passive movements of the stomach

- (a) Respiratory movements due to excursion of the diaphragm
- (b) Transmitted pulsations from the heart and aorta
- (c) Changes due to alteration of intra-abdominal pressure
- (d) Alterations produced by posture
- (e) Movements imparted by adjacent viscera, such as the colon

Active movements of the stomach

- (a) Intrinsic movements of the rugae
- (b) Circular peristaltic movements

By employing the technical factors aforementioned, all the passive movements of the stomach except those of respiration are eliminated from the kymogram, and only the intrinsic movements are recorded (fig 2).

To avoid misunderstanding, certain terms should be defined. Tonus is defined as the resting length of the muscle fibers. Peristalsis is a special form of contractile wave, which maintains the same width as it progresses across an organ in a definite direction. Spasms are contractions in the stomach or intestine which do not progress.

**Movements of the Rugae**—The movements of the rugae are best demonstrated with small amounts of a relatively thick mixture of barium in the stomach. The films may be taken with the patient erect, prone or in each position, depending on the adaptability of the appa-

The only movements of the rugae that are shown kymographically are those which are dependent on the movements of the whole stomach. These movements occur at the same time and proceed in the same direction as those of the walls of the stomach. In the frontal projection the rugae in the middle segment move less from

Fig 3—Roentgen kymogram of a filled normal stomach. Analysis of this kymogram is primarily for the study of peristaltic activity. The peristaltic waves in the fundus of the stomach are flat and of small amplitude while those of the pyloric region are deeper, narrower and more powerful. Peristaltic waves average from 2.2 to 3.8 waves per minute. A peristaltic wave lasts from fifteen to thirty seconds. The speed of progression of a wave averages about 25 cm. per minute.

ratus. Forssell's so-called autoplasmic movements of the rugae, which he described as being independent of the muscular walls, have not been recognized. It is probable that such movements occur over a longer period than one minute and for this reason are not recorded.

Fig 4—Roentgen kymogram of stomach involved with extensive carcinoma. Note the complete lack of peristaltic activity in the area invaded by the carcinoma. The inset is a conventional roentgenogram.

left to right. However, these may move more from front to back (fig 2). The width of the rugae changes with the passing of a peristaltic wave. At the level of contraction the folds of mucous membrane become narrower and the intervening space between the folds disappears. The movement is similar to that of the folds in an accordion. Kymograms of the rugae are helpful only in the diagnosis of hypertrophic gastritis.

**Movements of the Completely Filled Stomach**—In the stomach filled with the barium meal the kymographic study is primarily that of the peristaltic activity. In general the waves in the fundus of the stomach are flatter and in the pyloric region deeper and narrower, indicating that the peristalsis is more vigorous and rapid. The curves of movement in general are more rounded on the greater curvature than on the lesser (fig 3).

Peristalsis is analyzed on the basis of the following factors: amplitude, frequency, wavelength, speed of progression and tonus. The numerical values for the factors are those obtained by Stumpf<sup>1</sup> after analyzing 100 normal stomachs. We determined these values on twenty-five kymograms of normal stomachs and found them within the limits set by Stumpf.

1. Amplitude is the depth of the peristaltic wave. It is obtained on the kymogram by measuring the distance from the peak to the trough of a wave. It varies

with the degree of tonus and with different locations in the stomach. In the fundus on the larger curvature the amplitude varies from 5 to 10 mm and on the small curvature from 3 to 5 mm. In the pyloric region it varies from 15 to 20 mm.

2 Frequency is the rate of recurrence of peristaltic waves at the same place. It is read from the kymogram by counting the number of peaks in each frame. Since the kymogram was exposed for a minute, the number of these peaks is the frequency per minute. It averages from 22 to 38 waves per minute, which corresponds to a duration in time of about fifteen to thirty seconds.

3 Wavelength is the distance on the border of the stomach between two peristaltic waves at the same phase. It is recognized on the kymogram by noting the frames in which the waves are in a similar position. It varies between 6 and 10 cm.

4 Speed of progression is the rate at which the peristaltic wave passes through the stomach. It is calculated by multiplying the wavelength by the frequency. On the larger curvature it varies from 15 to 40 cm per minute, with an average value of about 25 cm per minute. These figures correspond to those previously obtained by Kastle.

5 The effects of tonus on peristaltic activity were shown in the early works of Cannon.<sup>10</sup> He noted that peristalsis was initiated by the simple stimulus of stretching the muscle fibers. Stumpf demonstrated this by making kymograms of the patient in the supine position with the radiographic table tilted to make the head lowermost. In this position the upper part of the stomach is distended, and peristalsis begins in the cardia. When the patient is in a standing position, peristalsis usually begins in the upper part of the fundus at the greater curvature. Weltz<sup>11</sup> from kymographic studies found that an increase of the tonus augments peristalsis. With a marked fall in tonus the peristalsis disappears. The amplitude of a wave is determined by the tonus. He expressed the opinion that tonus is the primary factor and tends to govern all active movements of the stomach.

*Emptying of the Stomach*—Kymographic studies favor Alvarez's<sup>12</sup> idea, that the emptying of the stomach is primarily caused by reflex changes at the pylorus which are dependent on peristalsis. The kymograms show that the pylorus opens only at a definite position on the peristaltic wave but not every time this position is reached on every peristaltic wave. Every second or third peristaltic wave normally transports chyme into the duodenum. Pyloric opening depends also on fluctuations in tonus, as Stumpf and his associates<sup>1</sup> have noted duodenal filling with an increase in tonus alone and again with peristalsis without variation in tonus. The emptying process is complicated and cannot be explained as a purely mechanical phenomenon. Certain unrecognized reflexes within the musculature must participate in the regulation of emptying.

*Normal Duodenum*—The movements of the duodenum are much faster than those of the stomach, indicating a quick passage of the opaque meal. The movements of the duodenum are as varied as its shape and position. Stumpf and his co-workers have classi-

fied the various ways in which the duodenum fills, but their clinical application is not apparent at this time and will therefore not be discussed.

*Gastritis*—Gutzeit<sup>13</sup> described the gastroscopic appearance of the rugae in hypertrophic gastritis as thickened and irregular, with superimposed areas of granulation and minute ulcerations. The rugae are rigid and their movements are suppressed. These changes are the result of edema and infiltration of the tissues. The chief kymographic signs of gastritis include a decrease in the mobility of the rugae and the failure of the folds to narrow and widen during the passage of a peristaltic wave. With the stomach completely filled, the peristaltic waves are frequently increased in amplitude and speed. These changes are considered to be the result of mucosal irritation. Stumpf expressed the belief that the kymographic films are of practical value in the diagnosis of hypertrophic gastritis. From our meager experience they seem promising.

In persons with atrophic gastritis it is difficult to follow the movements of the folds of mucous membrane, as they are smaller and thinner than in normal persons, and kymography offers little help in the diagnosis.

*Gastric Ulcer*—The roentgenologic diagnosis of gastric ulcer has been established by a large number of workers and is based on the detection of niches, filling defects, spasm, absence of motion fixation and local tenderness on pressure of the affected segment. The kymographic picture is not of diagnostic value but is interesting from the point of view of pathologic movement. In the kymogram the area of the ulcer is without active peristalsis but is affected passively by the movements of the adjacent portion of the stomach. The niche of the ulcer is seen to fill gradually as the tonus of the stomach is increased during the passage of a peristaltic wave. Stumpf has observed that the peristaltic waves in the portion of the stomach distal to the ulcer may be deep and forceful, while above the area of the ulcer retrograde peristalsis is present. The peristaltic wave is usually increased in speed and is smaller on the portion of the greater curvature opposite the ulcer.

In some instances, alterations in the peristaltic motion give rise to clinical symptoms. Deep, turbulent peristaltic waves may give rise to cramplike epigastric pains. In retrograde peristalsis there may be regurgitation, nausea or absence of symptoms. A deepening of the peristaltic wave in the normal direction usually does not cause subjective symptoms. Rapid changes in the type of peristaltic motion usually give rise to various subjective changes. From kymographic films Stumpf has often been able to predict the presence of pain by observing the character of the peristaltic waves and alterations in gastric tonus.

Gastric ulcers which have disappeared as the result of healing do not exhibit abnormalities of movement.

*Ulcer of the Duodenum*—Small niches can now escape observation even if the 6 mm grid which is best adapted for the study of duodenal ulcer, is used. The movements of large ulcers in the duodenum are passive similar to those of gastric ulcer. The films are usually exposed for about twenty seconds. The movements of the duodenum are so complex at the

area of radiologic investigation and the area is so small, that the organ is not well suited for kymographic work.

**Carcinoma of the Stomach**—The roentgenologic characteristics of carcinomatous infiltration have been established as consisting of filling defects, damage to the rugous pattern, rigidity of the gastric wall and absence of peristalsis. Most of these factors are clearly portrayed in the kymogram. Small tumors projecting into the lumen, which are well demonstrated in the conventional roentgenogram, usually do not influence the movements of the stomach. If a wall of the stomach is invaded, an area without regular movements, which is passively moved, appears in the kymogram.

There may be adequate peristaltic movement above the carcinoma, or distal to the infiltrative lesion the movement can be of a different type. Cramer<sup>14</sup> stated that the kymogram should not be avoided in the diagnosis of carcinoma because the lack of action in this area is an indication of the extent of carcinomatous infiltration, and therefore it is of value in determining the operability (fig. 4).

There is often no continuation of peristalsis beyond the defect. One has the impression of two different types of peristalsis, one on each side of the zone of infiltration. This is probably due to an infiltration of a sufficient area of the stomach muscle so that conduction in the muscle fibers is interrupted.

Even Stumpf<sup>15</sup> stated that the differentiation of benign polyposis or mucosal growths in small superficial tumors cannot be recognized, as the kymograms appear similar to those of normal stomachs. It was a hope that kymography would be a factor in the diagnosis of early carcinoma and of early infiltration lesions, but this hope has not been realized.

#### SMALL INTESTINE

Weltz<sup>16</sup> analyzed the movements of the small intestine by the kymographic method and was able to demonstrate (1) the already accepted "segmenting" movement which divides the food column into segments without onward propulsion, supposedly a mixing or churning process, (2) the common peristaltic waves, which are largely responsible for propelling the chyme onward, and (3) a previously unrecognized movement which he terms the "advancing movement through sectional contraction." A segment of the small intestine about one handbreadth wide contracts and squeezes its contents into the adjacent section of the intestine which is hypotonic. This movement is a localized contraction and does not progress down the intestine like a peristaltic wave. The "advancing segmental movement" is usually observed when large quantities of material enter the small intestine rather quickly.

#### COLON

The movements of the colon have been recorded on kymograms by Weltz<sup>16</sup> and Stumpf<sup>17</sup>. Colonic movements which advance the food column occur infrequently, approximately three times in twelve hours. This peristaltic activity recorded in cases of colonic obstruction is somewhat similar to that seen in the stomach. The individual peristaltic movements in the colon were deep, concentric waves lasting from seven

to eight minutes, which is about twenty times slower than gastric peristalsis. The very slow and gradual course of these movements, visible only on kymograms exposed six minutes, is obviously the reason why they have not been previously observed during fluoroscopic examinations.

The work of Weltz and Stumpf also demonstrated that the haustra of the colon undergo a fairly constant, fluttering type of motion as though they were attempting to mold their contents.

Both the peristaltic contractions and the feeble movements of the haustra are clearly demonstrated in their motion picture films made by photographing the image obtained by placing the kymogram in the kymoscope.<sup>18</sup>

#### CONCLUSIONS

1 Roentgen kymography is a practical method for studying the movements of the gastrointestinal tract.

2 The procedure offers a method for recording the details of peristaltic movement in both normal and pathologic stomachs, intestines and colons.

3 Kymography has stimulated an interest in the study of physiologic movements which may lead to a better understanding of functional disorders of the gastrointestinal tract.

4 Kymography is helpful in the diagnosis of gastritis but at this state of development is only of confirmatory value in the diagnosis of gastric ulcer, gastric cancer and zones of infiltration in the wall of the stomach such as syphilis.

#### ABSTRACT OF DISCUSSION

DR CHARLES F. DUDEN, St. Louis. There is a great deal to say about any new concept of any physiologic system. This has been brought more clearly before the members by Dr. Scott and his co-workers, probably, than in any of the previous published reports, which they have referred to adequately. The procedure is new in the realm of gastrointestinal study. It has been fairly well accepted, standardized and used diagnostically in the study of cardiograms and cardiokymograms, but it has not been applied, of course, to anything more than physiologic study in gastrointestinal work. On two or three occasions certain physiologic concepts have been verified by this particular method. The esophageal contractile waves, for instance, of solid boluses of food have been shown to travel approximately 5 or 6 cm in three seconds, and contractile waves of liquids have been shown to amount to from 13 to 15 cm per second. The ordinary contractile waves of the stomach have been shown to travel two or three peristaltic waves per minute, traversing the stomach in from twenty to twenty-five second cycles. It has also been shown here how stretching muscle fibers initiates peristaltic waves. This procedure probably can be referred to as photographic fluoroscopy, in which records are made of fluoroscopic items of the intestinal tract. It certainly offers a great field for checking previous physiologic concepts of the intestinal tract and perhaps for advancing certain elements of physiology of the digestive tract. It can be applied to diagnostic methods in only a supplementary way, however, because from this application or from these studies only the movements of the intestinal tract can be gaged. Nothing can be told of secretions and other things that are vitally important for diagnostic work, but it appears to me that early lesions of the intestinal tract which may not be seen by the naked eye in fluoroscopic manipulations can be demonstrated on kymographic films and the information be of great value. I say it is supplementary. Time will tell. Something has been seen here this morning that may lead in future years to further diagnostic and physiologic studies of the intestinal canal.

A METHOD FOR RECOGNITION OF  
BLOOD SUBGROUPS  $A_1$  AND  $A_2$ AS A MEANS OF AVOIDING TRANS-  
FUSION REACTIONSISRAEL DAVIDSOHN, M.D.  
CHICAGO

It has been recognized for some time that the selection of donors for blood transfusions according to the recognized rules for typing and cross matching of blood does not always assure transfusions without mild, moderate or even severe and fatal reactions, although the surgical procedure was beyond reproach.

Such unexplained reactions are frequent, much more frequent than the reports in the literature would indicate. They brought about an attitude of defeatism in surgeons who take it for granted that some reactions cannot be avoided and who accept that state of affairs as a necessary evil. This is particularly true with regard to reactions that are of only slight or moderate severity.

It is not feasible to review the very large number of contributions dealing with transfusion reactions. Only the more recent ones and only those with sufficient data concerning the blood groups will be referred to. Recently de Gowin<sup>1</sup> analyzed carefully eight fatal reactions in a series of 3,500 blood transfusions. Several references will be made to his case reports.

My purpose in this paper is twofold: (1) to consider the significance of the subdivisions of blood groups A and AB, so-called subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$ , as a possible cause of transfusion reactions and (2) to suggest a simple and practical method for the rapid recognition of these subgroups.

What is the evidence that subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$  may cause transfusion reactions? I will attempt to show that they may be responsible for reactions for one of two reasons: (1) because there is evidence that they may not be compatible and (2) because with the usual methods subgroups  $A_2$  and  $A_2B$  may not be recognized and may easily be mistaken for other blood groups.

## SIGNIFICANCE OF THE SUBDIVISIONS

Reactions of varying severity and even fatal ones have been reported when a donor of the same blood group as that of the patient was used and the typing and in some cases also the cross matching was done with care and according to all known rules. In some cases the tests were verified after the transfusion in an effort to find an explanation for the reaction. In some, errors were found in the grouping, most frequently due to the use of weak typing serums, in some, various other causes were disclosed and in others the reactions remained a mystery. A careful analysis of some reports fixes the responsibility on the disregard of the role of subgroups.

Statistical data suggest that, in blood transfusions with donors and recipients of the same blood group reactions are particularly frequent when both are of

group A.<sup>2</sup> One writer<sup>3</sup> even suggested that it is safer to use a universal donor for a patient of group A than to use a donor of group A. Ruedel<sup>4</sup> reported thirty-four transfusion reactions. In twenty-one of them blood group A or AB was involved. In thirteen the donor and recipient belonged to the same group, A in six cases and AB in one.

De Gowin<sup>1</sup> observed in his series of eight fatal reactions three deaths in patients of group A given a transfusion with blood of the same group and in a series of sixteen reactions five moderate or severe reactions with the blood in the same combination.

It could be argued that the large number of reactions involving group A is explained by its statistical frequency. This is admittedly a potent argument and it deserves serious consideration. On the other hand there is urgent need for more studies of the kind reported by Blinow,<sup>2</sup> who analyzed the subgroups in thirty-two transfusions of blood A to recipients of the same group. He noted five mild or moderate reactions in twenty-one transfusions when the subgroups of the donor and recipient were identical and nine more severe reactions in eleven transfusions, in two of which blood  $A_1$  was given to an  $A_2$  recipient and in nine of which blood  $A_2$  was given to an  $A_1$  recipient.

In several of his cases recipients of group  $A_1$  were given on one or more occasions blood of the identical subgroup without any reaction, while administration of blood of subgroup  $A_2$  was followed regularly by reactions of varying severity.

The importance of a consideration of subgroups is borne out by the case reports of de Gowin.<sup>1</sup> Patient 6, of group A, received five blood transfusions with blood of the same type but from different donors. Three were followed by severe reactions and two were free from reactions. In patient 13, two transfusions with blood of type A produced severe reactions, while a third transfusion, given between the two, was innocuous. Here too a different donor was used each time.

From the references mentioned and from many others, some of which will be cited later, it seems reasonable to assume that subgroups  $A_1$  and  $A_2$  as well as  $A_1B$  and  $A_2B$  are not always compatible with one another.

What are these subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$ ?

As early as ten years after Landsteiner's discovery of the blood groups, von Dungern and Hirschfeld<sup>5</sup> found that blood group A is not homogeneous. They absorbed the serum of a person of blood group B with the red cells of a person of blood group A and noted that the absorbed serum was able to clump the red blood cells of the majority of persons of group A, although it failed to clump the cells of some. This observation was confirmed repeatedly, and it led to the division of group A into two subgroups,  $A_1$  and  $A_2$ , and of group AB into  $A_1B$  and  $A_2B$ . These subgroups differ in their ability to clump when mixed with a standard anti-A serum from a person of group B or of group O. The red blood cells of subgroup  $A_1$  and  $A_1B$  clump much more readily and intensely than do the red cells

of subgroups  $A_2$  and  $A_2B$ , which may not clump at all if the agglutinating serum is of a low titer. The failure of red cells of subgroup  $A_2$  to clump is not infrequent, because serums with high titers of iso-agglutinins are quite rare. Of all A bloods, about 80 per cent belong to subgroup  $A_1$ , and about 20 per cent to subgroup  $A_2$ . Subgroup  $A_2B$  seems to be more frequent in proportion to subgroup  $A_1B$  than is subgroup  $A_2$  in proportion to subgroup  $A_1$ . There are considerable ethnic differences in the incidence of the subgroups.

There are two opinions at present concerning the nature of the difference between subgroups  $A_1$  and  $A_2$ . Some writers maintain that the difference is qualitative,<sup>6</sup> and they support their theory by the finding of agglutinin  $a_1$  in subgroups  $A_2$  and  $A_2B$  and of agglutinin  $a_2$  in subgroups  $A_1$  and  $A_1B$ . Agglutinin  $a_1$  clumps the cells of subgroups  $A_1$  and  $A_1B$ . It occurs often particularly in subgroup  $A_2B$ . It reacts best at low temperatures, but in some cases it works also at room temperature and occasionally even at body temperature.

Blinow<sup>2</sup> found in nineteen serums of subgroup  $A_2$  seven with a well developed titer and six with a low titer of agglutinin  $a_1$ . In seventeen serums of group  $A_2B$  the incidence was higher, nine with strong and three with weak agglutinins  $a_1$ .

Agglutinin  $a_2$  is very rare. It seems to be of an entirely different nature from  $a_1$  because it clumps red cells of group O in addition to those of subgroup  $A_2$  and the agglutination of cells is usually more pronounced in group O than in subgroup  $A_2$ .

The concept that subgroups  $A_1$  and  $A_2$  differ qualitatively is opposed by those writers<sup>7</sup> who say that the difference is merely quantitative manifested by a lower avidity of cells in subgroup  $A_2$  for the iso-agglutinating serum. That view is supported by the finding that cells in subgroup  $A_1$  are able to remove all agglutinins from an anti- $A$  serum, but their quantity must be larger and the process of absorption may have to be repeated.<sup>8</sup>

On theoretical grounds the use of a donor of subgroup  $A_1$  for a recipient of subgroup  $A_2$  should be more dangerous than the reverse procedure, because, as will be shown later, persons of subgroup  $A_2$  are more liable to have iso-agglutinins  $a_1$  against red cells of subgroup  $A_1$  and because reactions between the serum of the recipient and the red cells of the donor are most dangerous. In the combination of a donor of subgroup  $A_2$  and a recipient of subgroup  $A_1$  the danger exists too, but it is smaller because iso-agglutinin  $a_2$ , which reacts with red cells of subgroup  $A_2$ , is much less common in subgroup  $A_1$  than iso-agglutinin  $a_1$  in subgroup  $A_2$ .

That these hazards are not merely theoretical speculations is borne out by a case report of de Gown.<sup>1</sup> Patient 5 of group A was given blood of the same type without reaction. Four days later another donor of the same group was used after a preliminary cross matching. A fatal reaction followed, leading to death sixteen days after the transfusion. Retyping of the blood of the donor as well as of the recipient confirmed the original finding of group A. However, the serum

of the patient agglutinated and hemolyzed the red cell of the donor as well as of a person definitely of group O. Apparently the cross matching prior to the blood transfusion did not reveal the incompatibility. There is little doubt that the recipient belonged to group  $A_1$  and had the rare and exceptionally strong iso-agglutinin  $a_1$  and that the donor belonged to group  $A_2$ . That explains why the serum of the patient reacted with the red cell of the usually inagglutinable group O.

Similar risk exists when donors of group  $A_1B$  are used for recipients of group  $A_2B$ . Here the hazard is even greater, because the proportion of persons who have the agglutinin  $a_1$  is larger in subgroup  $A_1B$  than in subgroup  $A_2$ . The danger is enhanced by the opinion that a person of group AB is a universal recipient and that transfusions for patients of that group do not require cross matching. The concept of the universal recipient needs to be revised. It may henceforth be applied only to persons of subgroup  $A_1B$  whose blood is free of agglutinin  $a_2$  and to persons of subgroup  $A_2B$  whose blood lacks agglutinin  $a_1$ .

It is true as already stated that agglutinins  $a_1$  and  $a_2$  are as a rule active only at lower temperatures, but they may occasionally react even at body temperature as happened in de Gown's<sup>1</sup> case 5, already cited. Furthermore, there is no valid reason to assume that the failure to react *in vitro* guarantees that no harm is done *in vivo*, just as the opposite is true and as has been borne out by reported transfusions of incompatible blood which were without any obvious untoward result. It is possible that some of the mild and moderate transfusion reactions and particularly the late reactions are due to subgroup incompatibilities.

In evaluating transfusion reactions it should be considered that the so-called blood group properties A, B and O (the latter has been shown to be a positive antigenic property and not merely an indication of the absence of the other two) are actually present in all tissue cells and not only in the blood cells. The term cell groups would therefore be more appropriate than blood groups.

It seems to me that not enough attention is paid to the mild and moderate transfusion reactions. They are taken for granted and may be partly responsible for the failure of many blood transfusions to be of visible benefit.

The significance of subgroups  $A_1$  and  $A_2$  is not limited to incompatibility between them. There are reports in the literature of serious and fatal reactions due to failure to recognize subgroup  $A_2$ . Typing serums with low titers of iso-agglutinins are responsible. Typing serums are usually collected from typed specimens of blood or from donors with known blood group. Serums with high titers are rare and difficult to obtain. Variations in the strength of iso-agglutinins are known to occur. There is a physiologic variation associated with age in the titers of iso-agglutinins. The majority of newborn children have no detectable iso-agglutinin in their blood, although the agglutinogens are well established. The agglutinins appear usually in the course of the first year of life. Their titer rises gradually until a peak is reached in adolescence. Later a slow decline takes place.

It has been claimed often that there are in some diseases considerable and regular variations in the strength of iso-agglutinins. Most of these reports have not been corroborated. However, it seems well established that patients with chronic leukemia of any type have very

weak iso-agglutinins.<sup>9</sup> This is of particular importance because patients with leukemia are frequent recipients of blood, and cross matching tests with their bloods may not furnish the warning that the donor is not compatible.

How can the failure to recognize subgroup  $A_2$  affect a blood transfusion? The most common error is the assumption of group O instead of  $A_2$ , due to a weak agglutinating serum which failed to clump the weak red cells. Cross matching may in such a case be of little help or of no help, because persons of group  $A_2$  have the anti-B agglutinins and they may have an  $\alpha_1$  agglutinin against about 80 per cent of all persons of group A. In other words their serum may behave exactly like the serum of persons of group O. If such a false universal donor is used his blood may cause most severe and even fatal reactions. The danger is greatest if the blood is given to persons of group B or O, who always have agglutinins against  $A_2$  cells. A transfusion reaction due to the fact that a donor's blood of subgroup  $A_2$  with agglutinin  $\alpha_1$  was mistaken for group O was reported by Traum and Witebsky.<sup>10</sup> Mishaps will be more common when donors are selected on the basis of blood grouping alone without subsequent cross matching. A recent report of Levine and Katzin<sup>11</sup> shows that such practice still prevails, particularly with regard to universal donors.

Cross matching of the serum of the recipient and of the cells of the false universal donor may fail to show the true  $A_2$  nature of the donor's subgroup, on account of the low titer of iso-agglutinins in the blood of some patients and the low agglutinability of the cells of the donor, which is merely a repetition of the error that led to the false grouping in the first place.

De Gowin<sup>1</sup> recently reported two fatal transfusion reactions which can serve as excellent illustrations. The donor, used in both cases, and the recipients were determined to be of group O. A severe reaction set in during the transfusion in one case and shortly after in the other. One of the patients died four days and the other ten days after the transfusion. Rechecks of the blood of the patient and of the donor disclosed no incompatibility in either case. Three years later the blood of the donor was typed with a serum of a high titer and found to belong to group A. The subgroup was not determined in this case, but the discovery of the true blood group only after stronger typing serum was used suggests that it was probably  $A_2$ . That reactions do not necessarily follow the use of such incompatible blood is evidenced by the fact that the same donor was used as a group O donor for eight transfusions without reactions.

There is danger of a reaction when a false universal donor (in reality of group  $A_2$ ) is used for a patient of subgroup  $A_1B$ , on account of the possible though very rare presence of the agglutinin  $\alpha_2$  in the serum of persons of subgroup  $A_1B$ . Here the temptation to dispense with the cross agglutination is particularly great, because a presumably universal donor is used for a so-called universal recipient.

One can assume with equal justification the existence of a hazard in the use of a true universal donor for a

recipient of subgroup  $A_1B$  with agglutinin  $\alpha_2$ , because the latter may react with the cells of group O even more readily than with the cells of  $A_2$ .

A similar danger of a reaction between the rare agglutinin  $\alpha_2$  and the blood cells of subgroup  $A_2$  and group O exists when a true universal donor or an  $A_2$  donor mistaken for a donor of group O is used for a recipient of group  $A_1$  with the rare agglutinin  $\alpha_2$ .

One can still read that the so-called universal donor (blood group O) may be used safely without cross matching of the serum and red cells of recipient and of donor.<sup>12</sup> This idea is rapidly losing ground. The modern attitude is that the agglutinins in the serum of donors of group O frequently have high titers and that such donors may be dangerous. Another danger is the frequency of isolysins in the serum of group O, particularly for cells of group A. Such lysins may not be recognized if not thought of and not carefully looked for (de Gowin, case 8). The danger inherent in the use of universal donors is supported by the statistical evidence of the great frequency of reactions of varying severity after their use. Gray<sup>13</sup> had reactions in less than 10 per cent of a series of 500 blood transfusions but in 33 per cent in a series of forty transfusions in which donors of group O were used.

Severe reactions following the use of blood of group O were reported by Pari and Krischner,<sup>2</sup> McCandless,<sup>14</sup> Ruedel<sup>4</sup> and de Gowin.<sup>1</sup> Ruedel saw reactions in four transfusions when the recipient and donor belonged to group O. In de Gowin's series of eight fatal reactions three occurred in patients of type O who received blood of the same type, and six of the sixteen moderate or severe reactions took place in patients of group O given homologous blood. The high titers of iso-agglutinins in the serums of universal donors cannot account for all such reactions and can hardly be advocated as an explanation when the recipient as well as the donor is of type O. It seems likely that false donors of type O (actually of type  $A_2$ ) are responsible for some of these unexplained reactions.

The use of weak typing serums may be responsible for the failure to recognize subgroup  $A_2B$  and for mistaking it for B. This is probably not infrequent, because  $A_2$ , weak as it is by itself, is still more so in combination with B, which seems to have a depressing effect on agglutinin A.

Blood of such a false group B is particularly dangerous when given to a recipient of group B with a strong titer of agglutinins against A. Sometimes cross matching of the bloods may not expose the error if the serum of the recipient has a low titer of agglutinins. As has been mentioned, a low titer of agglutinins in the recipient does not necessarily preclude a reaction, even a severe one. A severe reaction after administration to a patient with blood of group B of 120 cc of blood supposedly of the same group was reported by Beck.<sup>15</sup> A subsequent check showed that a mistake in blood grouping was made and that the donor's blood was actually of group AB. The subgroup was not stated, but it is reasonable to assume that it was  $A_2B$ .

The possibility of failing to recognize subgroup A<sub>2</sub> is particularly great with infants and children, whose A<sub>2</sub> property is still weaker than that of adults. There is a well established variation according to age in the strength of the agglutinogens, though this is less marked than in the case of agglutinins.

#### RECOGNITION OF SUBGROUPS

How can these dangers of transfusion reactions due to the failure to recognize subgroups be avoided?

Speaking of unexpected transfusion reactions, de Gowin said "A more plausible interpretation is that for a small number of bloods our present laboratory methods are inadequate to detect all incompatibilities."<sup>1</sup>

A careful analysis of the reports in the literature suggests that in most cases the errors are due to the use

that sheep blood ought in turn to engender in the rabbit an immune serum against human blood of group A. Experiments confirmed his supposition. The serum of some rabbits inoculated with the blood of sheep was found by Schiff and Adelsberger, and by many investigators subsequently, to agglutinate the red cells of group A in much higher dilutions than the cells of groups O or B.

Some authors recommended such rabbit serum for blood grouping purposes.<sup>18</sup> It permits one to overcome two serious drawbacks of human isoserum, for it has a high titer and is readily produced. Thus it helps to eliminate the errors due to not recognizing the weakly agglutinating bloods of group A and due to mistaking them for group O or to mistaking subgroup A B for group B.

of typing serums with low titers of iso-agglutinins. Therefore it is imperative that only high titered serums be used for blood grouping, as was advocated by Coca<sup>16</sup> and others. Such serums are not easy to get.

I found that the titers of iso-agglutinins rise after injection of horse serum, particularly when serum disease develops, and I recommended the use of serum from patients with serum disease for blood grouping.<sup>9</sup>

Another source of potent grouping serum for type A cells has been used for several years in Germany but is little known in this country.

Schiff and Adelsberger<sup>17</sup> found that human blood of types A and AB produced in rabbits an immune serum with a high lytic ability for sheep blood. They ascribed this phenomenon to the presence of common antigenic fractions in the blood of sheep and in human blood of groups A and AB.

Seeing that human blood A was capable of producing a lysis against sheep blood, Schiff concluded

There still remains the necessity of differentiating subgroups A<sub>1</sub>, A<sub>2</sub>, A<sub>1</sub>B and A<sub>2</sub>B from one another to avoid incompatibility. Since von Dungern and Hirschfeld<sup>6</sup> reported their observations, several methods have been recommended.<sup>19</sup> Only a few of the more practical methods will be mentioned.

1. With the method of von Dungern and Hirschfeld,<sup>6</sup> serum of group B is absorbed with red corpuscles of subgroup A<sub>2</sub>. It then clumps only red cells of subgroup A<sub>1</sub>. The disadvantages of this method are as follows: High titered serums of group B are necessary, and these are difficult to find. After absorption

the serums do not keep well. Relatively large amounts of red cells of subgroup  $A_2$  must be readily available. According to Klopstock<sup>18</sup> this method is not absolutely reliable. It cannot be used for the differentiation of subgroups  $A_1B$  and  $A_2B$ .

2 Landsteiner and his associates<sup>20</sup> recommended the use of irregular agglutinin  $a_1$  for the recognition of subgroup  $A_1$  and of  $a_2$  for subgroup  $A_2$ . These agglutinins are usually weak, and  $a_2$  is difficult to find.

3 Serum of group B is absorbed with different quantities of red cells of group A. Small amounts of cells of subgroup  $A_1$  will remove completely the anti-A agglutinins, while large volumes (even one half of the volume of serum) of cells of subgroup  $A_2$  will absorb them only partially. According to Friedenreich and Worsaae,<sup>21</sup> the originators of this method, there are no transitions between the two subgroups when tested by means of absorption. This procedure is recognized at present as the standard method, with which the results of the other methods must be checked. However, it is cumbersome and time consuming and requires a great deal of high titered serum of group B and of red cells. It is therefore not very practical as a routine test.

These three methods are the most practical of a long list that have been published, but even the selected methods are not very convenient for routine use. This may be the reason why the determination of subgroups is not done as often as it should be.

To be of value as a routine procedure for blood grouping, the method for differentiation of subgroups  $A_1$  and  $A_2$  must be reliable but at the same time rapid and relatively simple. While considering this need, it occurred to me to attempt a solution of the problem by utilization of the common antigenic fraction of human blood A and of sheep blood.

As stated, Schiff and Adelsberger<sup>17</sup> produced a specific agglutinating serum against human red cells of group A by injecting sheep red cells into rabbits. However, their immune serum did not differentiate subgroup  $A_1$  and  $A_2$ .

The common antigenic fraction of human red cells of group A and of sheep red cells was shown by Schiff and Adelsberger<sup>17</sup> and by me<sup>25</sup> to be related to but not identical with the so-called Forssman heterophilic antigen.<sup>20</sup>

It is known that the Forssman antigen is thermostable and resists boiling. Schiff and Adelsberger were able to remove the anti-A agglutinins from their serum against sheep blood by absorption with boiled sheep cells. That being the case, I decided to try whether the injection into rabbits of boiled sheep blood would produce a serum against human blood A that would act differently toward the cells of subgroups  $A_1$  and  $A_2$ . The result fully justified my expectations.

**Preparation of Typing Serum**—Sheep blood was washed with physiologic solution of sodium chloride and centrifuged after each washing. The procedure was similar to the one used in the preparation of the suspension of sheep red cells for the complement fixation test for syphilis. A 20 per cent suspension of the

cells in physiologic solution of sodium chloride was boiled for thirty minutes on the water bath. Any loss due to evaporation was made up with distilled water. Rabbits were given from four to five intravenous injections of 25 cc of the boiled and thoroughly shaken 20 per cent suspension of sheep cells mixed with 75 cc of physiologic solution of sodium chloride at from three to four day intervals. The later injections were divided into several smaller portions and administered at about thirty minute intervals. Control animals were treated with similar suspensions of raw sheep blood. About seven days after the last injection, blood was obtained from the ears of the rabbits and tested for the presence of anti-A agglutinins.

If the results were satisfactory the rabbits were exsanguinated. Of eleven rabbits five produced satisfactory subgroup specific immune serums, two failed to respond and four died in the course of immunization.

The rabbits injected with boiled and with raw sheep blood produced anti-A group specific agglutinins equally well, however, the serum of the animals inoculated with boiled blood showed a sharp differentiation in the strength of the titer for the two subgroups. The results were confirmed by numerous checks with specimens of blood from 205 persons of group A and AB. 144 of subgroup  $A_1$ , thirty-six of subgroup  $A_2$ , eighteen of subgroup  $A_1B$  and seven of subgroup  $A_2B$ . All the results were corroborated by the absorption method, which is generally accepted as the standard test for the recognition of groups  $A_1$  and  $A_2$ .

It was deemed necessary to develop a technic which would (1) permit prompt recognition of feebly agglutinating subgroup  $A_2$  as well as of strongly agglutinating subgroup  $A_1$  but would not agglutinate either group B or group O, (2) differentiate subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$  clearly and unmistakably, (3) be simple and easily carried out and (4) be rapid enough to be applicable as a routine procedure under the conditions of emergencies as they often exist prior to blood transfusions.

**Titration of Rabbit Immune Serums for Typing of Subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$** —The serums were inactivated at 55 C for thirty minutes and titrated in different dilutions with specimens of blood of all groups and subgroups. Dilutions of the serums were prepared in test tubes. Approximately 2 per cent suspensions of red blood cells were prepared by adding one drop of whole blood to 1 cc of physiologic solution of sodium chloride. Two drops of the serum dilution were placed on slides within a circle made with a colored wax pencil. A drop of the blood cell suspension was added. The slides were tilted, placed under a Petri dish beside moist filter paper to prevent drying out and examined macroscopically and if necessary microscopically after five, ten, fifteen and thirty minutes. Two dilutions were selected. In one, at the end of five minutes there was distinct clumping of the red cells of subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$ , visible macroscopically, but the cells of groups B and O could not be seen macroscopically or microscopically to be clumped even at the end of thirty minutes. This dilution was found to be sufficient for the detection of even the weakest  $A_2$  factor. It was the diagnostic titer for the recognition of blood group A. The second dilution was the one which was capable of giving at the end of five minutes a clear and distinct clumping, recognizable with the naked eye, of red cells of subgroups  $A_1$  and  $A_1B$  but in which the red cells

25 Davidsohn Israel. Heterophile Antigen in Human Blood. *Arch Path* 6: 632-637 (Oct.) 1928.

26 Davidsohn Israel. Heterophile Antigens and Antibodies. *Arch Path* 4: 776-806 (Nov.) 1927. Buchsinder Leon. Heterophile Phenomena in Immunology. *Arch Path* 19: 841-880 (June) 1935.

of subgroups  $A_2$  and  $A_2B$  at the end of five minutes showed no clumping either macroscopically or microscopically, at the end of ten minutes showed no clumping macroscopically and at the most hardly discernible clumping microscopically and even at the end of thirty minutes showed only clumping which had not become visible to the naked eye. The second dilution was called the differential titer for the recognition of subgroup  $A_2$ .

The titration of rabbit immune serum is recorded in table 1. Serum 21, with an A group titer of 1:10 and with a differential titer of 1:50, is an example of a satisfactory typing serum for the differentiation of the two subgroups. Serum 29 is an example of an unsuitable serum, and serum 36, which was produced with raw sheep cells, has a high anti-A titer but shows no clear-cut differentiation between subgroups  $A_1$  and  $A_2$ . It can be used very well for the recognition of group A.

For table 2, several examples were selected from my records to show how the method works in practice. The first two examples show the behavior of subgroups  $A_1$  and  $A_2$ , the following seven show the behavior of

previous columns. The last column contains the results of absorption of human B (anti-A) serum with two different quantities of the red cells. While cells of subgroup  $A_1$  removed the anti-A agglutinins completely even when only one thirty-second volume was added to the serum, cells of subgroup  $A_2$  failed to do it even with one-half volume. The titers of the serums before the absorption are stated at the foot of the table. This method is the most reliable confirmation of the subgroup. Every determination of the subgroup with the rabbit serum was checked with the absorption method. There was full agreement of the two methods.

**Technic of Typing of Groups A and AB and of Subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$** —After the two titers of the immune rabbit serum have been determined with the outlined procedure, the lower dilutions (group A titer) will help to identify the group A and AB specimens and the higher dilution will help to determine the subgroups. At the same time the serum of group A (anti-B) should be set up for the recognition of group B and preferably a type O serum as a control. The results can be read in from five to ten minutes.

TABLE 2—Determination of Subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$ , Comparison of Results

Red Blood Cells of Cases	Typing with				Titration with Immune Rabbit Serum				Subgroups	Absorption of Human Serum* (B Anti A)

subgroups  $A_1B$  and  $A_2B$ , of which more examples were selected because they show greater variation in their agglutinability and because it is thought that they are more difficult to separate.

The second and third columns show the results of typing with human serums of groups A and B. The technic was the accepted method of Vincent. Serums with high titers were used. It is apparent that the differences in the agglutinability with the human serums are in no relation to the subgroups. In some instances, as in No. 223 ( $A_1B$ ), the cells clumped much less distinctly (+) than in No. 37 ( $A_2B$ , ++++). The fourth column shows the agglutination with the group dilution of rabbit serum as determined by titration. The cells of subgroup  $A_1$  were clumped more vigorously than those of subgroup  $A_2$ , but there was never the slightest difficulty in seeing the pronounced clumping of any specimen of subgroup  $A_2$ . The clumping of subgroup  $A_1B$  was equally pronounced. Most specimens of subgroup  $A_2B$  had to be read with the microscope, but the clumping was always clearcut and unmistakable. The differential dilution for the separation of subgroup  $A_2$  is recorded in the fifth column. The lucidity of the differentiation is manifest. In the next column the results of titration of the red cells with the rabbit immune serum are recorded to emphasize the differences in titers between subgroups  $A_1$  and  $A_2$ . Then follow the designations of the subgroups as determined in the

#### SUMMARY

Clinical experience, as it is expressed in the literature, suggests (1) that the selection of a donor according to known methods does not assure the absence of blood transfusion reactions, (2) that unexpected reactions are not uncommon when a donor of the same blood group as that of the patients is employed especially when the group is O or A, and (3) that reactions are particularly frequent when so-called universal donors are employed.

Available serologic data suggest (1) that subgroups  $A_1$  and  $A_2$ ,  $A_1B$  and  $A_2B$  are not always compatible, (2) that subgroups  $A_2$  and  $A_2B$  are not infrequently mistaken for blood of other groups, particularly for O and B, and (3) that some transfusion reactions, even fatal ones, are well explained by these circumstances.

The method presented offers two advantages. 1. The high titered, easily produced and highly specific rabbit immune serum permits prompt recognition of blood group A and AB, including the feebly agglutinating subgroups  $A_2$  and  $A_2B$ . 2. A proper dilution of the serum, as determined by titration, makes it possible to differentiate subgroup  $A_2$  from  $A_1$  and  $A_1B$  from  $A_1B$  without delay. Both procedures can be carried out within five minutes.

California Avenue at Fifteenth Place

27. The determination of subgroups  $A_1$ ,  $A_2$ ,  $A_1B$  and  $A_2B$  for exclusion of paternity is discussed in the reprints.

## ABSTRACT OF DISCUSSION

DR NATHAN ROSENTHAL, New York It seems that the method of approach for the differentiation of two types of group A may be important from a practical standpoint. It will be especially useful for detecting the group AB, which is usually important in paternity tests. Usually this can be done by high titer serum, but if this is not available the new method proposed here may prove very useful. The relation of these blood groups to reactions from transfusions must also be considered. The three main types of reaction are those due first to impurities or foreign protein present in the water or left in the apparatus from previous transfusions. This accounts for most of the chills and to some extent, febrile reactions. By proper cleansing methods, Dr Lewisohn and I have shown that such reactions may be reduced from between 12 and 20 per cent to less than 3 per cent. Second, reactions from incompatible blood are now rather rare. In fact we have seen no such reaction within the past ten years, since proper cross matching can be done in the laboratory. Third, reactions from compatible blood. In the past ten years we have noticed only three such reactions, the symptoms arising are comparable almost identically with those from incompatible blood. We have noted, however, that such reactions are not necessarily related to group A but are found in other groups as well. Fortunately, this type of reaction is very rare. I believe that this additional test for two subgroups of A may prove to be of some importance after further investigation.

DR KATHARINE M. HOWELL, Chicago I have been acquainted with the work of Dr Davidsohn on the differentiation of blood groups  $A_1$  and A, the purpose of which is to decrease the deleterious reactions occasionally following blood transfusions. I have been interested in these studies because our laboratory types blood for five or six thousand transfusions a year and in spite of employing serums of the highest titer available for blood group determinations and the greatest care in the cross matching of serum and corpuscles, an occasional difficulty in typing or an unexplained reaction occurs. This is usually encountered in finding a compatible group A donor for a group A patient, or for the so-called universal recipient, group AB which also contains the A agglutinogens. A serum of high titer is essential for separating  $A_1$  and A and therefore the method described by Dr Davidsohn may be of the greatest advantage since heterophile immune serum almost always has a higher agglutinin titer than the human serum available for blood grouping. The present method for separating  $A_1$  and A by absorption has been found time consuming and not practical for the routine laboratory blood grouping tests.

DR ISRAEL DAVIDSOHN, Chicago Not enough attention is paid to mild and moderate blood transfusion reactions. It was shown that transfused blood remains longer in the circulation of the recipient when the transfusion is not followed by a reaction of one kind or another than when there is a reaction. The danger of not recognizing correctly subgroup AB is illustrated by a case report of Beck, a German surgeon, who had a large experience in blood transfusions. He transfused a patient of group B with the blood of a donor of supposedly the same group. A severe reaction followed. A retyping of the donor disclosed that he belonged to group AB. The subgroup was not determined, but the circumstance that the true group was detected only after stronger typing serum was used suggests strongly that it was subgroup AB. When cells of known blood groups are used as controls to check the group of the unknown serums it is essential to use cells of subgroup  $A_1$  and not of A. Dr Rosenthal referred to the medicolegal application of subgroups. I did not go into it because time did not permit. However I am using the rabbit serum for the differentiation of subgroups  $A_1$ ,  $A_2$ ,  $A_3$  and AB along with anti-M and anti-N typing serums and with the anti A and anti B grouping serums with satisfactory results. The method is particularly valuable for the typing of blood of infants whose agglutinogens are weaker than in later life. Some infants who are found to belong to group O may behave like subgroup i when retested after a few months. The existence of the irregular iso agglutinin  $\alpha$  which reacts with red cells

of group O, supports Schiff's concept of group O as possessing a positive and specific antigenic character that can be determined by proper serums. The new concept should replace the idea that group O is the one without any antigenic agglutinable properties. The symbol O must stand for a letter and not for a number.

SULFANILAMIDE IN TREATMENT OF  
NONSPECIFIC INFECTIONS OF  
THE URINARY TRACT

ANSON L. CLARK, M.D.

OKLAHOMA CITY

During the last eight years great progress has been made in the treatment of infections of the urinary tract. The diagnostic work and the experimental and clinical observations necessary for the foundation of this progress had already been accomplished, but they had not become common knowledge. Before therapeutic advance could be made, a study of the micro-organisms commonly found in the urinary tract had to be supplemented by possible methods of treatment of sufficient value to interest the experimental workers in this field.

As recently as ten years ago it was felt that patients complaining of frequency, urgency and burning on urination did so because the urine excreted by the kidneys was more acid than comfortably could be borne by the mucous membrane of the urinary tract. Soon, however, it was discovered that these patients were relieved when the acidity of the urine was increased, which appeared paradoxical. Cultures of the infecting organism showed that the most common offender, namely the gram-negative bacillus, was inhibited in its growth as the acidity of the urine increased and that the relief afforded the patient was due to the effect of the change in acidity on the infecting organism rather than to the direct action of any drug on the mucous membrane.

Medical therapeutics temporarily gave way to helpful dietary measures, which stimulated studies along these lines, until chemotherapy at length produced experimental and clinical results exceeding the most enthusiastic expectations. There are accordingly today three outstanding therapeutic agents which, when used with careful evaluation of their effect on offending micro-organisms, will go far to relieve patients suffering from urinary tract infections. These are sulfanilamide, mandelic acid and neoarsphenamine. Chief among these in the interest aroused among urologists is sulfanilamide.

Before a more careful analysis of the action of sulfanilamide is made, it should be emphasized that mandelic acid and neoarsphenamine retain a specific place in combating urinary tract infections. It should also be remembered that methenamine, which has proved its worth through the years, remains a valuable adjunct to treatment. No drug has had to stand more rapid investigation of its therapeutic possibilities than sulfanilamide.

Because of the prominence of the patients to whom the drug was first administered, and because of the conservatism of the large medical center which first enthusiastically reported its therapeutic possibilities, sulfanilamide was heralded by the fourth estate as the great medical discovery of the century. By the same

token, less than a year ago one of the early investigators predicted that during the ensuing twelve months the toxic effects of the drug would be responsible for numerous fatalities.

Before this warning could be broadcast to the medical profession, a drug concern not versed in the chemical effects of the solvent combined this new compound with a dangerously toxic liquid, with the result that the lay press grimly counted deaths which were apparently, but not in reality, due to this medical discovery. And so, having withstood the overenthusiasm which frequently accompanies new medical measures, sulfanilamide is now found to be of great therapeutic value in the treatment of genito-urinary infections when it is carefully used, with proper observance of its toxic possibilities and a thorough knowledge of its clinical limitations.

#### REVIEW OF THE LITERATURE

The first applications of sulfanilamide in clinical practice were used in various streptococcal infections in 1935 but it was a foregone conclusion that the success with which the new remedy was employed for a wide variety of infections would stimulate efforts for its use against the organisms peculiar to the genito-urinary tract. Early in the same year Temming,<sup>1</sup> impressed with the rapid improvement of a 7 week old infant suffering from facial erysipelas after administration of sulfanilamide, tried the new remedy with three young infants with pyuria. Given by rectum it produced remarkable results, leukocytes and albumin disappeared rapidly from the urine after an immediate and dramatic drop of the high temperature to normal.

Pernice<sup>2</sup> of the Marburg pediatric clinic was the next to apply sulfanilamide in urologic practice. He gave it orally to eighteen children of various ages, with good results. He proved that the drug is effective not only against streptococci and staphylococci but also against colon bacilli. To prevent recurrence, he gave it for a week after the urine had become normal.

Maraun<sup>3</sup> reported that prontosil<sup>4</sup> had been given orally to thirty-eight children of various ages, in twenty-one of whom infection with *Bacillus coli* or *Bacillus paracoli* was producing severe symptoms. Satisfactory results were obtained in all but five cases.

Unshelm<sup>5</sup> tried prontosil in twenty-three cases of pyuria at the Rostock pediatric clinic with encouraging if not uniformly good results. In all but two instances the infective agent was *B. coli*, in one both *B. coli* and *Proteus ammoniae* were present. Fourteen of the patients were followed for from one to seven months, during which time not one showed pathologic urinary changes. No difference was observed between acute and chronic involvement in the time required to relieve the infection.

Klein<sup>6</sup> in 1936 reported that prontosil was being used in all cases of pyuria in the pediatric clinic of the University of Breslau and that it was given both orally and intravenously, the latter method being preferred for infants.

Early in 1937 Meissner<sup>7</sup> reported his use of sulfanilamide in eight cases of cystopyelitis, seven patients being women and one a man. These patients gave a history of infection of from four days' to several months' duration. In most of the cases *Bacillus coli communis* was the infecting organism, against which sulfanilamide proved to be bactericidal after treatment lasting from three to ten days. In all the drug was given orally.

Turk<sup>8</sup> reported a series of sixteen cases of acute and chronic renal disease in the University of Hamburg Hospital. After two or three days of treatment with sulfanilamide all were free from symptoms, and in an average of five to six days they were also bacteria free. Three patients with pyelitis of pregnancy were clinically cured but were not free from bacteria after treatment.

Helmholz<sup>9</sup> became interested in sulfanilamide as a urinary antiseptic from in vitro experiments which showed it to have a marked bactericidal action on all the common bacteria found in the urinary tract except *Streptococcus faecalis*. He observed that it was effective both in acid and in alkaline urine but more so apparently, in alkaline, that it is present in urine in the free and conjugated form, both of which forms appeared to be bactericidal, but that the conjugated form seemed to be more potent in this respect. He tried the effect of sulfanilamide on six different organisms found in the urine: *Streptococcus faecalis*, *Escherichia coli*, *Aerobacter aerogenes*, *Proteus vulgaris*, *Pseudomonas aeruginosa*, and *Staphylococcus aureus*. He found that *Staphylococcus aureus* was the most easily destroyed, while *Streptococcus faecalis* was the most resistant of the group.

Helmholz and Osterberg<sup>10</sup> observed that sulfanilamide is very useful in treating some conditions with which mandelic acid and the ketogenic diet fail, for example infections due to *Proteus ammoniae*. The organism flourishes in an alkaline urine, in which sulfanilamide is more effective than in acid urine. On the other hand, sulfanilamide failed to have any effect on *Streptococcus faecalis*, which is however controlled by mandelic acid. The results in three series of patients to whom sulfanilamide was administered showed that the urine was definitely bactericidal to organisms commonly found in infections of the urinary tract.

Cook and Buchtel<sup>11</sup> began using the drug with great caution, because of the conflicting reports that had reached them. With very small doses they noted little benefit when the substance was given orally. Later results however, when larger doses were given, were very encouraging. It is their opinion that if the efficiency of sulfanilamide in alkaline urine continues to be demonstrated, the drug should be of inestimable value in treating infections of the urinary tract due to urea-splitting bacteria, with which it has been always impossible to obtain a sufficient degree of acidity to inhibit the growth of the organism.

## IDENTIFICATION OF THE INFECTIVE AGENT

In the diagnosis of infections of the urinary tract it is of great importance that the offending organism be identified promptly, in order that appropriate therapeutic measures may be administered. Hence in the second portion of the freshly passed two glass specimen from the male or in a catheterized specimen from the female the gram-positive coccus, the gram-negative bacillus and the paired diamond-shaped *Streptococcus faecalis* have been watched for as the most common offenders. Failing to find these in the urinary sediment, the diagnostician must then eliminate the possibility of a chronic specific infection or an infection due to an acid-fast bacillus.

The physician who uses his microscope only on rare occasions instead of on every occasion will not be able to treat urinary tract infections intelligently. Only rarely is one required to have the elaborate laboratory equipment necessary for identification of the micro-organism by culture. The method described by Pelouze makes gram staining of the centrifuged urinary sediment a quick and easy procedure which should be used at all times.

During the past year, clinical and laboratory data have shown that sulfanilamide is an effective agent in combating the gram-negative bacillus, from the common *Escherichia coli* to the less frequent but more refractory *Aerobacter aerogenes*, as well as the infrequent *Pseudomonas* and the hitherto troublesome and uncontrollable *Proteus ammoniae*.

For those unfortunate persons who are afflicted with a urinary tract infection with *Proteus ammoniae* as the offending organism, sulfanilamide has been a great discovery. For satisfactory results most urinary antiseptics require increased acidity in the urine, which the action of *Proteus ammoniae* has frequently made impossible. It is fortunate that at last there is a bactericidal agent which will act in an alkaline urine, an agent which is invaluable to the patient who is afflicted with this urea-splitting organism, which is so frequently a forerunner of encrusted alkaline cystitis and pyelitis.

It should be remembered that occasionally *Streptococcus faecalis* is found accompanying the gram-negative bacillus and that sulfanilamide has no effect on this organism. Its presence should be suspected and the urine, though clear, examined bacteriologically when the complaints of the patient, such as frequency and burning at urination, persist. *Streptococcus faecalis* (group D, hemolytic streptococcus) may cause extreme discomfort with but little evidence of reaction on the part of the patient in the form of haziness or cloudiness of the urine. It is remarkable how few pus cells will at times be found in urine teeming with this type of bacteria. At such times it is important to investigate microscopically the stained urinary sediment. A routine urinalysis will miss the irritating micro-organism because of the scarcity of white blood cells in the specimen. The discomfort of the patient should emphasize the necessity for close cooperation between the clinician and the laboratory. If its presence is confirmed, intravenous administration of neoarsphenamine may prove a most helpful measure. Clinical results show also that the use of mandelic acid accompanied by increased acidification of the urine is effective in eliminating *Streptococcus faecalis*.

In the case of gram-positive coccus infections other than those due to *Streptococcus haemolyticus*, the clinical

responses have varied considerably and the percentage of satisfactory results apparently does not approach that obtained when the gram-negative bacillus is involved. The gram-positive micrococcus so frequently found in the anterior portion of the urethra of the male may be more effectively eliminated from the urinary tract by sulfanilamide than can the various species of staphylococci. When sulfanilamide does not produce the desired result, small intravenous doses of neoarsphenamine accompanied by oral administration of methenamine should be prescribed.

## TOXICITY OF THE DRUG

My clinical experience in using sulfanilamide in a large number of instances in which the age and general condition of the patient differed over a wide range has confirmed the conclusions of Marshall, Emerson and Cutting,<sup>12</sup> who said:

In spite of the fact that this study indicates that sulfanilamide is a relatively nontoxic substance, the drug is not devoid of toxicity. The minor toxic manifestations to be expected in man from our animal work and from the greater individual variation in diseased patients would seem to be no contraindication to the use of the drug when definite therapeutic indications exist. However, owing to the fact that the drug can possibly produce serious toxic symptoms in the hypersensitive individual, as well as the known occasional idiosyncrasy of a serious nature, sulfanilamide should not be used indiscriminately.

It is well known from experimental study that acidosis is produced by excessive doses of sulfanilamide. Since the excessive dose may vary considerably with each patient, it would seem advisable to reduce the possibility of lessening the alkali reserve by the administration of some alkalinizing agent. Furthermore, the sulfanilamide excreted into the urinary tract is more effective in inhibiting the growth of the invading bacteria when the  $pH$  of the urine is increased. So, from the standpoint of lessening its toxicity and increasing the effectiveness of its action, a moderate dose of sodium bicarbonate or some similar alkalinizing agent should be given in conjunction with the drug.

As it is also observed that a decrease in renal function accompanies an excessive dose of sulfanilamide, caution should be exercised in determining the amount of the drug administered when the age of the patient or the symptoms seem to indicate renal insufficiency. Clinical observations show a wide variation in the apparent renal tolerance for this new compound. Reactions are common, and frequently, in order to obtain the desired result, some of the lesser toxic manifestations, such as lassitude, slight headache, some anorexia or even nausea without vomiting, may necessarily be imposed on the patient. If the dose is within safe limits for the patient, I have usually found that these symptoms subside by the second or third day, even though the dose is maintained as first prescribed. The questions of when and how to prescribe sulfanilamide therefore require for their answer considerable experience in administration of the drug and careful study in each case in which its use is considered advisable.

## DOSE OF SULFANILAMIDE

No standard dose of this drug can be established, since the amount must vary with the individual patient. In a younger person the kidneys will excrete the drug more rapidly and will thus lessen its level in the blood.

12 Marshall E. L., Emerson K. Jr. and Cutting W. C. Para-aminobenzenesulfonamide: Absorption and Excretion. J. A. M. A. 108: 953-958 (March 20) 1937.

On the other hand, if the substance is excreted slowly by the kidneys because of decreased renal function the level in the blood will be higher even though the dose is small.

The ambulatory patient is unable to tolerate the same amount of the drug that may be given safely to a patient resting in bed. This was strikingly illustrated recently in a patient who tolerated satisfactorily 100 grains (6.5 Gm.) of sulfanilamide daily while hospitalized yet had toxic symptoms while taking 40 grains (2.6 Gm.) daily when employed at light manual labor. To emphasize further the wide variation in the doses tolerated by different persons, it is interesting to note that a patient somewhat dissatisfied with this earthly existence took fifty-eight 5 grain sulfanilamide tablets, or 290 grains (18.85 Gm.), at one time, with no more serious effect than a transient decrease in the respiratory rate and a marked drowsiness, both of which symptoms were entirely relieved within twenty-four hours by forced fluids and respiratory stimulants.

In passing, it is worthy of note that while this patient was greatly discouraged because of a subacute specific urethritis and prostatitis which had failed to respond to previous therapeutic measures, the excessively large dose eliminated the infecting organism from his urinary tract.

In the treatment of acute infections of the urinary tract, the various modes by which sulfanilamide can be administered add to its value as a curative agent. When, as so frequently happens, gastrointestinal upsets make oral administration impossible, the drug can be given intramuscularly, subcutaneously, intravenously or by rectum.

#### EVALUATION OF RESULTS

Infections of the upper part of the urinary tract, both acute and chronic, respond well to sulfanilamide therapy when this is applied with due reference to the type of infecting organism and when proper consideration is given to the limitations of any urinary antiseptic in the presence of calculi, stasis or tumors. Sulfanilamide should be borne in mind as a valuable preoperative aid in preventing the troublesome sequelae which may follow surgical procedures, cystoscopic manipulations or other manipulations of the urinary tract. With uncomplicated pyelitis it has been my experience that the course of the infection is considerably shortened both clinically and bacteriologically. I have found that bacillary infections are more easily eradicated by sulfanilamide than are the coccic infections.

With cystitis my results have shown no uniformity. The acute trigonal cystitis often observed in women due to bacillary infection, has responded very well; the acute symptoms often clearing up within twenty-four hours after administration of sulfanilamide. I continue the treatment, nevertheless, until it is evident that all infection has been eliminated. On the other hand, bladder infections occurring after operations on the bladder neck have not yielded at once to sulfanilamide therapy, the infection usually persisting for several weeks despite its administration. However, after all necrotic material has been eliminated I have found this drug to be helpful in relieving residual infections.

With nonspecific prostatitis, although sulfanilamide serves to diminish the extent of the infection, as evidenced by microscopic examination of the expressed prostatic secretion, it has been my experience that recurrence frequently follows, and the prostatitis becomes as pronounced as before. The size of the doses seems to make no difference. The less satis-

factory results obtained in the treatment of nonspecific infections of the prostate gland may be explained by the variation in the type of infecting organism. Prostatitis caused by the gram-negative bacillus may respond rapidly, while the inflammatory condition due to a gram-positive coccus will show little improvement.

#### SULFANILAMIDE AND UNDULANT FEVER

In the southern and southwestern parts of the United States, when one has eliminated all other possibilities in the search for the infective agent, one finds that a considerable percentage of urinary tract infections are due to the micro-organism that causes undulant fever. The public health reports of recent years have shown that no state in the Union is altogether free from this type of disease. In the North, however, where pasteurization of milk is the rule rather than the exception and where Bang's disease has been practically eliminated from dairy herds, this type of urinary tract infection is encountered less frequently. On the other hand, examination of dairy cattle below the Mason and Dixon line has shown that nearly 50 per cent of the milk-producing animals are infected with this important bacterium.

Only within the last two years have satisfactory diagnostic procedures been available, and only since the advent of sulfanilamide has there been a satisfactory therapeutic agent for this type of urinary tract infection.

It is worthy of note that several foreign authors (Groues,<sup>13</sup> Berger and Schnetz,<sup>14</sup> Suchier<sup>15</sup> and Thevenet<sup>16</sup>) have lately drawn attention to the great value of sulfanilamide in the treatment of undulant fever. In the United States Toone and Jenkins<sup>1</sup> have recently reported a case in which the diagnosis was confirmed by blood culture and in which negative cultures followed administration of sulfanilamide over a period of eleven days. Stern and Blake<sup>18</sup> used sulfanilamide effectively in three cases of acute brucellosis.

It is a significant observation that in the sections of the United States where undulant fever is comparatively common there are many instances in which recurrent prostatitis and cystitis have been wrongly attributed to infected teeth, infected tonsils or other possible foci, while the real cause, which is undulant fever, has not been discovered because of failure to realize how widespread is the occurrence of this disease. It is accordingly important that the clinical picture associated with this rather frequent form of urinary tract infection be recognized.

Brucellosis, however, is often more deceptive than the usual classic picture would indicate. The fever is prone to remissions, and during these remissions the patient may or may not suffer from some of the complaints that beset him during the more acute stage. If he happens to consult his physician during one of the intervals, it is easy to see how the true nature of the malady might escape detection.

Sulfanilamide applied in the treatment of urinary tract complications from the disease has shown most

satisfactory results. According to my experience, however, it must be supplemented with a carefully administered vaccine to raise the immunologic responses of the patient to a point where the brucellosis will be completely controlled.

#### CONCLUSIONS

Sulfanilamide in the treatment of nonspecific urinary infections is proving to be a valuable addition to the urologist's armamentarium when employed with due caution and in the proper doses. It must be borne in mind that every case is an individual problem, that doses cannot be fixed by any general standard and that reactions are frequently observed. There should be a careful study of each patient, especially with regard to renal tolerance. The blood level of sulfanilamide should be watched throughout the period of its administration. A considerable experience with the drug is required for a proper understanding of its effects and for a proper appreciation of the conditions under which it should be prescribed. With suitable indications and in the right hands sulfanilamide is capable of producing brilliant results in the treatment of nonspecific urinary infections. Failures may be due to lack of proper identification of the infecting organism, since there are wide differences in the susceptibility of organisms within the urinary tract to the action of sulfanilamide.

### THE USE OF SULFANILAMIDE IN 1,625 CASES OF GONORRHEA IN THE MALE

BARNEY SILVER, MD

AND

MANNING ELLIOTT, MD

Director, Division of Venereal Diseases, City of Los Angeles  
Health Department  
LOS ANGELES

Dees and Colston<sup>1</sup> introduced sulfanilamide in the treatment of gonorrhea in February 1937. Their preliminary report indicated that it might end the search for a practical check of this widespread venereal disease. Since then, diverse results have been reported. Reuter's<sup>2</sup> most closely approximated the original report, but Potter,<sup>3</sup> in a series of 225 cases, reported only 35 per cent cures. Brunet's<sup>4</sup> percentage of cures was also low. Johnson and Pepper's<sup>5</sup> results were so disappointing as to evoke an editorial<sup>6</sup> in *THE JOURNAL* pointing to less than 50 per cent cures and calling for extreme caution in the use of the drug.

Although the drug itself was completely exonerated by the Council on Pharmacy and Chemistry of the American Medical Association for the deaths follow-

ing the use of Massengill's elixir of sulfanilamide, it is as yet not completely free from this onus in the public mind. Moreover, proof that the drug itself is toxic is adduced by the reports of fatal and near fatal cases by Borst,<sup>7</sup> Young,<sup>8</sup> Schwentker,<sup>9</sup> Marshall<sup>10</sup> and Harvey.<sup>11</sup>

The final estimate regarding the use of sulfanilamide for gonorrhea must rest on a comparison of the beneficial effects with the incidence and frequency of toxic reactions. To this end we wish to contribute the results obtained from its use with 1,625 male patients. The size of this group warrants statistical analysis. The study was limited to male patients, as the proof of cure in women is notoriously difficult to establish.

The first series, 200 consecutive patients, were studied particularly to determine what part the duration of the disease, degree of involvement and degree of side reactions play in the curative response to the drug. For this purpose the patients were given maximum tolerance doses without additional local therapy unless the failure of the drug to control the disease was obvious. Unless contraindicated by serious toxic reactions, treatment consisted of 80 grains (5 Gm.) for two days, 60 grains (4 Gm.) for the following four or five days and from 20 to 40 grains (1.3 to 2.6 Gm.) for at least two weeks. In this series only patients observed for three months were included. They were seen from three to five times weekly during treatment and one time weekly during follow-up. Diagnosis was established by smear or, in a few cases, by positive culture. Proof of cure included (1) complete absence of pyuria and (2) at least three negative smears after provocation by sounds, silver nitrate in the posterior urethra, prostatic massage, the use of alcohol and intercourse. The persistence of pus in the prostatic fluid was disregarded if these tests failed to excite clinical or laboratory evidence of the specific organism. The results in this first series have been correlated in table 1.

This table shows the drug to be of unprecedented efficacy in the treatment of gonorrhea. In 58.5 per cent of the cases cure was obtained in less than one month without accessory local treatment. The exact time of the disappearance of the gonococcus is indeterminable, so the date of cure was considered to be the date of the initiation of the provocative tests if these were followed by no evidence of recurrence. The average time from the first day of treatment to the start of the provocative tests was only twenty-one and one-half days.

A second group of patients, comprising 21.5 per cent of the total patients treated, showed less response to the drug, but, with the addition of local therapy, likewise gave results vastly superior to those obtained with previous forms of therapy. Adjuvant treatment consisted of instillations of mild protein silver for the anterior and acute anteroposterior urethritis. Through and through irrigations of potassium permanganate were used for the chronic anteroposterior infections. Because of the protective action of the sulfanilamide, much earlier use of posterior medication was possible. The average period of cure was only forty-five days.

Read before the Section on Urology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

The results with the forty remaining patients, comprising group 3, must be considered as comparatively unsuccessful. In some, adequate administration was impossible because of toxic side reactions, in others the infection was prolonged or complicated despite the drug

response to the drug is not dependent on the extent of the infection. The one and salient exception, which was repeatedly confirmed, is that sulfanilamide will not clear up a gonorrhea focus until free drainage is established. The most striking examples of this fact were four cases of infected Tyson's glands. The freely draining urethra quickly cleared of all evidence of infection, whereas gonococcus loaded pus could be expressed at each visit from the poorly draining Tyson's glands. Cure was obtained when these glands were destroyed by electrocautery. Similarly, gonorrheal prostatic abscesses and periurethral abscesses failed to respond until digital or surgical rupture, after which rapid progression toward cure was obtained. Because of this concept, patients with acute phlegmonous prostatitis are now given large doses of sulfanilamide to ward off epididymal involvement, and soon thereafter attempts at digital expression of the nondraining pus is attempted. Such patients, who previously often responded poorly to sulfanilamide therapy, now show a most uniform immediate improvement in their condition.

Table 2 illustrates the value of the drug in the treatment of various complications of gonorrhea. The relief of pain in acute epididymitis and the relief of stricture in prostatic involvement were extremely satisfying, often occurring in less than twenty-four hours. With these complications particularly the drug seemed heaven-sent panacea, and only the rare patient failed

Chart 1—Is response correlated to side reactions of sulfanilamide?

There were nine cases of drug incompatibility, in two there were very severe subjective symptoms, in six administration of the drug had to be discontinued before cure could be obtained because of the fever-rash syndrome and in one toxic cyclopia contraindicated further use. Twenty-one patients showed definite but slow improvement attributable to the added influence of sulfanilamide therapy. In six cases clinical symptoms would abate dramatically each time the drug was used but would recur just as regularly after cessation. In only four cases was there a complete absence of clinical effect.

A review of chart 1 shows two thirds of the patients presenting side reactions, ranging in severity from mild uneasiness to fever, cyanosis and severe dermatitis, necessitating hospitalization or confinement to their home, but, as can readily be seen from the blocked diagrams, the relative incidence of the various degrees of side reactions were essentially the same with all types of therapeutic response. It is probable therefore that the mechanism of cure rests on a basis different from that which produces the constitutional upset.

Potter<sup>3</sup> and Mahoney<sup>12</sup> report the results of sulfanilamide with chronic gonorrhea to be better than those with acute gonorrhea. In this series, as the block figures in chart 2 indicate, there was no significant difference in the ratio of cure to the duration of the infection prior to treatment.

Similarly, cross tabulation of the initial diagnosis with curative response to the drug, as shown in chart 3, shows strikingly similar ratios. Apparently the cura-

Chart 2—Is response correlated to duration of gonorrhea prior to administration of sulfanilamide?

to respond with at least symptomatic improvement. As will be brought out in an analysis of the second series, sulfanilamide has been of even greater importance in the preventing of these unfortunate complications.

Although no gonorrheal ophthalmia was seen in these 200 cases, the response with this dreaded complication is the most satisfying of all. Of twenty patients treated at the Los Angeles County Hospital, nineteen were cured with dramatic success and the twentieth, although

having a minor relapse, retained the sight in both eyes. This is in keeping with the results quoted by Willis<sup>13</sup>

Only one patient with gonorrheal arthritis was seen in this series and he responded well, but this was contrary to the experience in the urologic section of the county hospital, in which only seven of twenty-two patients obtained much relief.

Table 3 shows the frequency and diversity of the side reactions encountered. Weakness and dizziness are so often present that they should be considered as concomitants rather than as complications. As can be seen, in only a few cases were the symptoms so severe as to contraindicate further use of the drug. The "drunk feeling" and loss of sleep so frequent of occurrence were never followed by serious consequences and were therefore disregarded.

Dyspnea appeared so frequently that suspension of the work was considered during the first days of our study, but continued observation assured us that this alarming symptom is innocuous in the absence of clinical cyanosis.

The truly serious side reactions, as reported by many authors<sup>14</sup> were usually ushered in by an influenza-like syndrome of generalized aching and a temperature ranging from 100 to 103 F. This was usually followed by a rash, which appeared in from twenty-four to forty-eight hours and simulated the eruptions of measles or secondary syphilis. Two of the patients with rash were mistakenly quarantined in the first days of the drug's use. One third of the rashes were of the photo-sensitive type, with sharp lines of demarcation at the covered parts of the body. In only one of these cases was the prognosis doubtful. This patient had generalized edema but went on to a complete recovery in fourteen days.

Investigation of the cases of the toxic rash syndrome revealed an interesting fact pertaining to the urine. From twenty-four to forty-eight hours previous to the onset of rash, the urine became deep orange or slate colored. The color was so similar to that observed in hematoporphyrinuria that examinations for hematoporphyrin were carried out early in June 1937. Because of some technical difficulty the tests were reported as negative, and not until January 1938 did we again try to identify this as the causative pigment. At this time the urine of three successive patients with rash showed positive spectroscopic reactions for hematoporphyrin. The presence of this metabolic disturbance is possibly the key to many of the bizarre neurologic complaints reported and to the occasional nerve palsies reported by Potter<sup>3</sup> and Bucy.<sup>15</sup> Mason, Courville and Ziskind<sup>16</sup> in their monograph on the porphyrins, described similar phenomena and the induction of hematoporphyrinuria

by benzene-derived drugs. Four of this series of patients had definite paresthesias, and another had a definite psychosis during the period of the drug administration. Since our recognition of the significance of the pigment in the urine, we have used its appearance as a signal for discontinuance of therapy, and the incidence of rashes has diminished.

The most serious toxic manifestation was the development of acute toxic hepatitis (reported elsewhere). The patient on his own initiative took 15 grams (1 Gm) of sulfanilamide six weeks after its use had been discontinued because of the fever-rash syndrome.

Chart 3—Is response correlated to extent of gonococcal involvement?

Within five hours there developed an urticarial rash, which disappeared in several days, but the patient became progressively worse and on the sixth day was definitely jaundiced. Evidence of liver damage progressed, with the icterus index climbing to 200 and the urea nitrogen content dropping to 8 mg per hundred cubic centimeters of blood. After five weeks of hepatic insufficiency the patient finally recovered, apparently with complete recovery of liver function.

The toxic side reactions may therefore be grouped into four classes:

- 1 The generalized systemic reactions, including malaise and the fever-rash syndrome.
- 2 The hemopoietic depressions, including the agranulocytic and hemolytic anemias reported but not found in this series.<sup>17</sup>
- 3 Toxic involvement of either the central or the peripheral nervous system.
- 4 The sensitization phenomena similar to those which occur with arsphenamine, cinchophen and aminopyrine.

Table 4 emphasizes the necessity for using even greater perseverance in testing for cure and caution before allowing the patient sexual license. There are two factors which may bring this drug into disfavor: the toxic reactions just discussed and the spread of the disease by patients who have been lulled into a false sense of noninfectiveness by the abrupt disappearance of discharge. Pelouze<sup>18</sup> had great stress on the necessity

Ophthalmitis	10	1		Dramatic eye saving results

the use of sulfanilamide but cure was disproved by exacerbation which occurred after cessation of therapy or was induced by the provocative tests. In twenty-

three cases this occurred once and in fourteen, twice, and in four there were three distinct remissions without cure. Yet we feel that if the tests of cure are instituted at least a week after all therapy has been discontinued and include passage of sounds, instillation of silver nitrate, prostatic massage to obtain discharge, the use of alcohol, and intercourse, with thorough search of smears after these procedures, the remissions can be definitely differentiated from cure. In only three of the cases in which we had pronounced the patient cured has the last year's observation proved wrong.

The second series, comprising 1,425 patients, as mentioned previously, were treated under a different plan. The limitations of the clinical facilities and the reluctance of the patients to attend the clinic as frequently as we felt necessary prevented the use

TABLE 3—Analysis of Subjective Side Reactions With Sulfanilamide

Symptom	Number of Patients	Percentage of Patients	Comment
Weakness	12	5.6	Most frequent but of little significance
Dizziness	67	23	Same
Dyspnea	60	30	Only 2 patients had to discontinue use of drug on this account
Headache	31	16.5

Discontinuance of drug due to side reactions	17	8.5	
Urteritis	1	0.5	
Toxic necrosis liver	1	0.5	Case report elsewhere
Peripheral neuritis	0	0	1 case known outside this series
Hemolytic crisis	0	0	No hemoglobin content less than 50 per cent
Agranulocytosis	0	0	Frequent blood counts with toxic patients 3 cases of comparatively mild leukopenia

maximum tolerance doses of the drug. The previous experience with toxic side reactions convinced us that without close supervision the dangers of a fatal mishap were great. An attempt was made to see the patient at least twice weekly during treatment, and if this was impossible only small doses of sulfanilamide were prescribed. The average patient was instructed to take 8 grains of sulfanilamide for the first two days, but an exception the mildest symptoms called for immediate discontinuance until the next visit. The maintenance doses were definitely less than those prescribed in the first 200 cases. More dependence was placed on accessory local therapy, and this was prescribed early in the course of treatment in most cases. Despite the zealous efforts of the overworked truant officer, it was impossible to keep the patients in attendance until all tests of cure had been completed. The results in this large group probably more closely approximate those which can be expected by the average practitioner and in the public health control of gonorrhea.

19 Carpenter C. M. The Protective Effect of Sulfanilamide Against Gonococcus Toxic in Mice read at the fourth annual session of the American Neisserian Society Washington D. C. May 16, 1938.  
20 Jones W. Ray Sulfanilamide May Revolutionize Laboratory Identification of Gonococci Am. J. Syph. Gonorr. & Ven. Dis. 22: 349 (May) 1938.

Table 5 illustrates what one may expect under these conditions. Forty-seven per cent of the patients showed excellent curative response taking less than a month for cure. With 23 per cent cure was effected with much greater ease and celerity than could ever be expected without the use of sulfanilamide. With 19 per cent the gonorrhea was prolonged over two months or use of the drug could not be continued, because of side reactions. The remaining 11 per cent of the patients so successfully eluded the truant officer that the nature of their response could not be determined.

The occurrence of only sixty-three complications was in great contrast with the proportion of approximately 15 to 20 per cent which was observed in the days antedating sulfanilamide. This was paralleled by a striking reduction in the number of patients with gonorrheal complications admitted to the general hospital. During the last six months of 1936 189 patients were admitted with acute adnexal and metastatic involvement, during the same period in 1937 the figure was reduced to seventy-eight, and less than half of these patients had been given the benefit of sulfanilamide therapy prior to the development of their complications. The comparison of the thirty-one day average of clinic attendance for this series of 1,425 patients with the eighty-three day average for 2,000 patients in 1936 is another proof of the value of this drug.

Of 1,425 patients, 102, or 7 per cent, were unable to tolerate the drug. As can be seen, the fever-rash syndrome occurred in approximately 4 per cent. In none of these cases was the outcome doubtful, probably because of smaller doses of the drug and earlier discontinuance whenever evidence of the peculiar urinary pigmentation occurred.

TABLE 4—Reliability of Curative Criteria (200 Cases)

	One Apparent Relapse	Two Apparent Relapses	Three Apparent Relapses
Complete clinical remission on test of cure	23 patients	14 patients	4 patients
Discharged as cured after tests but returned with recurrence	3	0	0

TABLE 5—Second Series (1425 Patients)

	No of Patients	Percentage
Excellent results—cure in less than one month	681	47.8
Good results—cure in less than two months without development of gonococcal complications	223	22.7
Unsuccessful	267	18.7
One visit	154	10.8
Side reactions causing discontinuance of drug	102	7.1
Average clinical attendance		31.0 days
Average clinical attendance in 1936 prior to use of sulfanilamide		82.8 days

Of sixty-three gonorrheal complications occurring in this series, only fourteen occurred during administration of sulfanilamide. The rest occurred either prior to or after the cessation of its use, making a total of less than 1 per cent of complications during the administration of the drug.

#### SUMMARY

In the first series, with close observation and maximum tolerance doses of the drug, three fifths of the patients showed a cure in less than one month with no

accessory treatment. In another one fifth the results were far superior to what might be expected without the use of sulfanilamide, cure occurring in less than two months and with a mild course. With the remaining one fifth its use could not be classed as a success, either because of intolerance or because of failure of the drug to alter the course of the disease from what might be expected with the usual treatment. The effi-

TABLE 6—Side Reactions Causing Discontinuance of Drug (102 Patients)

Occurring after cessation of therapy	30	2.1

ciency of the drug was found to be independent of the degree of side reactions, the duration of the disease prior to its use or the extent of the involvement of the urinary tract. One exception to this rule was with non-draining gonorrheal recesses. Side reactions were frequent and diverse. Of 1,425 patients treated under conditions which would probably closely approximate the average, 50 per cent showed excellent results, with cure in less than a month, and one fourth had a comparatively mild illness and cure within two months. With the remaining one fourth the results were unknown or were not completely successful, because of intolerance to the drug, or the disease was not appreciably different than before the era of sulfanilamide. None of the 1,625 patients died and none had any marked blood dyscrasia. One almost fatal toxic necrosis of the liver and one alarming attack of cyanosis occurred.

#### COMMENT

Even the most conservative consideration of these results confirms the statement that the use of sulfanilamide is of unprecedented efficacy in the cure of gonorrhea and its complications in the male. Only one other method produced comparable results, the expensive and dangerous hyperpyrexia. Most students of the public health aspect of gonorrhea agree that hyperpyrexia could not be a significant factor in any control program because the expense alone eliminates the possibility of its use by all except the comparatively wealthy. Yet it is well recognized that the gonorrheal reservoir is the mass of young and comparatively indigent persons. Even if government subsidy were to provide the necessary funds, only the overzealous would subject a patient with uncomplicated gonorrhea to a procedure which carries a mortality varying from 0.5 to 5 per cent. Sulfanilamide, on the other hand, is an inexpensive drug, easily administered perhaps, from recent experience, much too easily. Superficially,

it too is subject to the criticism that the treatment is more dangerous than the disease

We concede that with the male the use of sulfanilamide will carry a higher mortality than gonorrhea itself. We do not feel that the danger is inherent in the use of the drug but realize that much self administration will unquestionably lead to some fatalities. Moreover, members of the medical profession must realize that the same fatal outcome may occur with their own prescription unless frequent clinical and laboratory observation is insisted on. We feel strongly, however, that gonorrhea is a disease which cannot be thought of in terms of mortality. It must be realized that the immediate and the distant morbidity of gonorrhea is incomparably more forbidding than simple mortality statistics indicate. In loss of work gonorrhea ranks second only to the common cold. Often a long series of gonorrheal complications have laid the patient up for from weeks to months, resulting in hardship on an entire family of dependents. Not only financially but socially the problem has great significance, because of the untold number of sterile unions directly attributable to gonorrhea in one of the partners. Finally, one must realize that, although for the male gonorrhea carries a negligible mortality, for the female it carries an ultimate mortality of from 1 to 2 per cent, not from the gonorrhea itself but from the pelvic operations it necessitates.

We propound still another argument to warrant our continued use of sulfanilamide in all cases of gonorrhea despite our concession that its use will give a higher mortality than the disease alone. Gonorrhea, like any other highly infectious disease, increases in geometric progression to the number of infected carriers. Candid urologists everywhere admit that heretofore the average duration of gonorrhea as treated throughout the country was not six weeks, as was optimistically written in many textbooks, but probably in the neighborhood of from four to six months. With the aid of sulfanilamide, 75 per cent of the patients should be cured in well less than eight weeks. We feel that this marked decrease in the number of gonorrheal carriers at any one time must inevitably result in the reduction of gonorrhea to a minor control problem from its present forbidding stature.

We feel therefore that sulfanilamide must be considered in the same light as the arsphenamines, of unparalleled value in the control of a widespread and highly communicable disease and a drug which demands caution and intelligence in its use and which, if properly used, should be the solution of what has been a most trying problem from both an individual and a social point of view.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DR CLARK AND DRs SILVER AND ELLIOTT

DR A. ELMER BELT, Los Angeles. My experience tallies with that of Anson Clark, who has found sulfanilamide effective in dealing with almost all infections of the urinary tract except that by *Streptococcus faecalis*. To this exception I must add infection by *Streptococcus viridans*. I have also found its effectiveness low with the gram negative cocci, especially *Staphylococcus aureus*. Clark's careful summary teaches that a considerable amount of investigation of the patient's condition is necessary in order to use the drug properly. Examination of urinary sediment in the fresh mount and stained specimen, cultures of urine and determinations of pH are advocated. In my experience the level of sulfanilamide in the blood is important, since it has been found that in 50 per cent of cases of failure

there has been a persistently low concentration of the drug in the blood. This may be due to a hypersecretion from too great fluid intake. When a level of only 4 to 6 mg. is present in the blood I lower the fluid intake, discontinue coffee and tea and increase the dose of sulfanilamide until a level of 11 mg. is obtained. In sulfanilamide physicians have at last a urinary antiseptic which acts on both sides of the urinary tract—on the blood and on the urine—and therefore, unlike mandelic acid is effective when the secretory power of the kidney is poor. In patients with an impaired renal secretory mechanism the blood level mounts rapidly and an early estimate may prevent too heavy an intake of the drug. The absorption rate of sulfanilamide is known to be rapid. Absorption is complete within four hours after oral administration. To the list of adverse reaction, cyanosis, dyspnea, acidosis, deafness and nausea, I must add the occurrence of extreme dermatitis and exfoliation of the exposed parts of a man of pink complexion after exposure to sunlight. This lasted ten days in spite of withdrawal of irritants, sunlight and the drug. All other unpleasant side reactions disappear at once after withdrawal of the drug. I am especially proud of the excellent summary presented by Drs. Silver and Elliott of an extremely large group of cases of gonorrhea treated by the Los Angeles Health Department. Work of this nature is often a little casual and uncontrolled, but I have great confidence in the care, accuracy and intelligence of Barney Silver. I wish to enlarge on one point he has made. He has noted that a search for the site of the persistent lesion in patients who have shown recurrences after sulfanilamide therapy often reveals a walled off lesion which has to be treated locally before sulfanilamide becomes effective. This tallies with my experience and leads me to mention the use of sulfanilamide in association with artificial fever. I have found that in 83 per cent of cases of failure with sulfanilamide alone cure was later achieved with a combination of sulfanilamide and artificial fever.

DR JAMES R. DILLON, San Francisco. With the development of chemotherapy it has become incumbent on urologists to study more closely and observe the reaction and response of the patient to the particular treatment, and we are approaching the category of the dermatologist in our ability to shift from one drug or form of treatment to another to meet the individual requirements. It was brought out by Dr. W. F. Braasch a year ago that the specific treatment may eliminate the organism producing the acute condition but that another submerged one will persist as a chronic offender, resisting all efforts at chemotherapy. After a period of chronic inflammatory reaction pathologic and anatomic changes may take place which demand adequate drainage for the kidney and bladder as well as clearing up of foci of infection. I should like to stress two points regarding sulfanilamide. 1. After an infection has responded and has been apparently cured, if a recrudescence is produced by the same organism it frequently fails to respond to the second course of treatment. 2. Patients who sometimes show violent reactions to the customary doses of an ordinary pharmaceutical product of sulfanilamide will frequently tolerate a kind of sulfanilamide carrying a proprietary name and a possibly better guaranty of purity. Damaged kidneys frequently cannot handle heavy doses of any urinary antiseptic, and smaller doses should be used for acute or subacute conditions, with possibly a better result.

DR W. RAY JONES, Seattle. Sulfanilamide, while a most efficient remedy, has multiplied the difficulties of proving the presence or absence of gonococci. Too many sulfanilamide treated persons, classed as cured by the ordinary clinical and laboratory methods, have later communicated the disease. Conversely, there is more difficulty than ever before in proving that other organisms are not gonococci. The Gram stain fails because both gonococci and the other organisms change their characteristics or mutate to meet the change in environmental conditions. The clinician must either be his own technician or work in closest collaboration with one to safeguard the patient in diagnoses of gonorrhea under these conditions. For a presumptive diagnosis it may be necessary to rely on seeing organisms growing on, about and in between the epithelial cells. Points to remember are that gonococci on epithelial cells stain deeply, have sharper outlines and are arranged in better clusters and that the diplococcal arrangement may be irregular. Final diagnosis rests on either finding typical organisms or no typical

forms for a sufficiently long period to justify considering the person noninfectious. Sulfanilamide has multiplied the technician's work and added greater uncertainty to the value of his results.

DR WIRT B. DAKIN, Los Angeles. I wish to present a new "believe it or not" incident. The officers on a submerged submarine noticed that one of their sailors was cyanotic. The vessel was promptly brought to the surface. With hatches open they rushed to their base, where the patient was hospitalized. The submarine's oxygen apparatus was overhauled but nothing found wrong. This incident cost the navy (American taxpayers) about \$5,000. The sailor had been treating himself with sulfanilamide. On being discharged from the navy hospital he consulted a civilian urologist and said "Doctor, you must not repeat what I have told you. If the navy officers found this out I should be hung by the heels from the tallest yardarm."

DR ANSON L. CLARK, Oklahoma City. Dr. Helmholtz has been kind enough to emphasize the infecting organism *Streptococcus faecalis*. In diagnosis when this type of micro organism is present may I make a plea for closer cooperation between the clinician and the laboratory? Recently I had a report from the laboratory of a large hospital that the urine showed short-chained streptococci. Such a report would lead one to believe that sulfanilamide would be of therapeutic value. In examining the slide carefully myself I found the diamond-shaped streptococci in pairs typical of *Streptococcus faecalis*. This organism apparently is not inhibited in its growth by sulfanilamide. May I again suggest that urologists familiarize themselves with brucellosis because of the important effect this type of infection may have on the urinary tract? Therapeutic measures in the treatment of brucellosis vary widely, from administration of vaccines to fever therapy. In my experience a carefully prepared vaccine, such as the Parke Davis product has given the most uniformly satisfactory results. It must be remembered that the dose usually suggested is much larger than should be given if one would avoid the unpleasant complications many have encountered in giving undulant fever vaccine.

DR HENRY F. HELMHOLTZ, Rochester, Minn. I want to emphasize one thing about the bacteriologic examination of the urine. It is outstanding that *Streptococcus faecalis* is the one organism that apparently grows almost as well in a solution of sulfanilamide as it does in a broth culture so that it cannot be hoped that sulfanilamide will cure an infection caused by *Streptococcus faecalis*. In cases in which sulfanilamide has been administered, one not infrequently sees *Escherichia coli* disappear from the urine only to find that a pure culture of *Streptococcus faecalis* remains. In such cases there unquestionably has been a double infection. Owing to the fact that *Escherichia coli* overgrows the various organisms in the urine, it appears to be the only infecting organism. Sulfanilamide therapy eliminates all *Escherichia coli* organisms leaving merely *Streptococcus faecalis* on culture. In going over some of my old records of treatment with methenamine the ketogenic diet and mandelic acid, I found when the infection was clearing up that *Escherichia coli* disappeared first and that a few colonies of *Streptococcus faecalis* remained on the plates. Thus *Streptococcus faecalis* is also resistant to these other forms of therapy, which fortunately will end the infection with a few extra days of treatment. Strangely enough if treatment is discontinued before the urine is sterilized it will be found that within a few days only *Escherichia coli* will be present and it will not be possible to see *Streptococcus faecalis*. This same thing applies to *Escherichia coli* and *Pseudomonas*. At the Mayo Clinic my associates and I have observed two cases now in which after elimination of *Escherichia coli* a pure culture of *Pseudomonas* was obtained. In both cases there were small stones in the kidney and we were never able to clear up the infection. There is one other point I should like to mention namely that *Staphylococcus aureus* apparently is the organism most susceptible to sulfanilamide therapy, and yet the clinical results are poor in cases in which this organism is present. I think this probably indicates that the infection caused by *Staphylococcus aureus* is not a superficial infection but that the deep tissues are involved and the sulfanilamide does not reach the organism in sufficient concentration to kill it. Certainly staphylococcal septicemia and osteomyelitis do not yield readily to sulfanilamide therapy.

## SURGICAL LIGATION OF A PATENT DUCTUS ARTERIOSUS

### REPORT OF FIRST SUCCESSFUL CASE

ROBERT E. GROSS, M.D.

AND

JOHN P. HUBBARD, M.D.

BOSTON

The continued patency of a ductus arteriosus for more than the first few years of life has long been known to be a potential source of danger to a patient for two reasons. First, the additional work of the left ventricle in maintaining the peripheral blood pressure in the presence of a large arteriovenous communication may lead eventually to cardiac decompensation of severe degree. Second, the presence of a patent ductus arteriosus makes the possessor peculiarly subject to fatal bacterial endarteritis. While it is true that some persons have been known to live to old age with a patent ductus of Botalli, statistics have shown that the majority die relatively young because of complications arising from this congenital abnormality. Dr. Maude Abbott<sup>1</sup> presented a series of ninety-two cases which came to autopsy in which it was shown that the patient had had a patent ductus arteriosus without any other cardiovascular abnormality. Of these patients, approximately one fourth died of bacterial endarteritis of the pulmonary artery and an additional one half died of slow or rapid cardiac decompensation. The average age of death of patients in this series was 24 years.

The complications arising from the persistence of a patent ductus arteriosus would seem to make surgical ligation of this anomalous vessel a rational procedure, if such a procedure could be completed with promise of a low operative mortality. Dramatic results have previously been obtained in persons with cardiac enlargement and decompensation resulting from a peripheral arteriovenous aneurysm when the short-circuiting vessels have been ligated or excised. On similar theoretical grounds, future cardiac embarrassment should be averted if a shunt between the aorta and the pulmonary artery could be removed. It would also seem plausible to expect that the shutting off of the anomalous stream of blood pouring into the pulmonary artery would lessen the formation of the thickened endothelial plaques within the pulmonary artery, which are so likely to be the seat of later bacterial infection. The surgical approach to the aortic arch and pulmonary conus having been studied previously in animal experimentation,<sup>2</sup> it seemed within reason that a patent ductus could be adequately exposed in man and possibly ligated without undue danger. It was therefore decided to undertake the operation in a child who presented the classic signs of a patent ductus arteriosus. At the age of 7 years she already had cardiac hypertrophy, which developed presumably from the embarrassment resulting from the anomalous communication. It was to be expected, therefore, that she would have increasingly severe disability in the future, aside from the danger of having bacterial endarteritis develop.

## REPORT OF CASE

**History**—L. S., a girl aged 7½ years, entered the hospital Aug. 17, 1938, for study of her cardiac condition. The family history was irrelevant. She was born normally at full term. No cyanosis was noted at birth or during the postnatal period. The records of the hospital where she was born give no information about an examination of the heart at that time. At the age of 3 years she was seen in the cardiac clinic of another hospital, where it was found that she had physical signs suggesting congenital malformation of the heart. At that time she had a precordial thrill and a loud murmur. The carotid pulsations were abnormally marked, and pistol shot sounds could be heard over the brachial and femoral arteries. The blood pressure was recorded in both arms as 104 mm of mercury systolic and 0 diastolic. There was definite cardiac enlargement, as shown by teleoroentgenograms. The diagnosis made at that time was "congenital malformation of the heart with a patent ductus arteriosus."

During the next four years she was seen in several different hospitals, where the same diagnosis was made. At no time

Daily blood pressure readings of the patient with a patent ductus arteriosus before and after operation. Prior to operation the large ductus opening from the aorta produced a low diastolic pressure. Following operative closure of the ductus the diastolic pressure rose to twice its former level. The average daily diastolic pressure preoperatively was 38 mm of mercury. The average diastolic pressure postoperatively was 80 mm of mercury. The arrow points to the time of operation.

had cyanosis been observed. Dyspnea developed after moderate exercise, and her physical activities had been limited accordingly. She had never had peripheral edema or other evidence of cardiac decompensation. Frequently the child had been conscious of "something wrong in the chest" and her mother spontaneously offered the information that she had heard a "buzzing noise" in her daughter's chest when standing nearby.

**Physical Examination**—At the time of admission, the patient was slender and undernourished. The pulsations of the carotid arteries were abnormally forceful. The radial pulse was of the Corrigan type, and a capillary pulsation was readily seen. The veins over the chest were somewhat prominent. There was a precordial bulge. The heart was definitely enlarged by percussion, the enlargement being for the most part to the left. Over the entire precordium there was a prominent coarse thrill which was most intense in the third interspace to the left of the sternum. This thrill was continuous but was accentuated during systole. There was a rough "machinery" murmur heard with maximal intensity over the pulmonic area to the left of the sternum in the second and particularly in the

third interspace. It was continuous throughout the cardiac cycle but like the thrill was greatly accentuated during systole. It was transmitted to the left along the third interspace and into the axilla with only slightly diminished intensity. The systolic element was heard faintly over the vessels of the neck and could be heard clearly in the right axilla and over the mid-thoracic region posteriorly. Blood pressure readings were respectively right arm 115/40, left arm 110/50, right leg 150/55, left leg 140/40 mm of mercury. There was no clubbing of the fingers, and no evidence of peripheral edema. The liver edge was palpable at the costal margin. The examination in other respects was negative.

**Laboratory Data**—A 7-foot x-ray film of the chest showed the transverse diameter of the heart to be 117 cm, compared to an internal diameter of the chest of 20 cm. There appeared to be definite enlargement of the left ventricle. There was questionable prominence of the pulmonary artery. A mottled increased density around the lung hilus was interpreted as representing circulatory congestion. Fluoroscopic examination showed a "hilar dance." An electrocardiogram was normal, showing no deviation of the axis. The red blood count was 5,080,000 cells per cubic millimeter and the hemoglobin was 85 per cent (Sahli). Circulation time with dchydrocholic acid was 10 and 8 seconds, respectively, on two tests.

**Operation**—August 26, operation was undertaken (by R. C. G.) under cyclopropane anesthesia. The approach to the mediastinum was made through the left pleural cavity antero-laterally. Incision was made through the left third interspace, cutting the third costal cartilage, and the third rib was retracted upward. As the left lung was allowed to collapse inferiorly, an excellent view was gained of the lateral aspect of the mediastinum. The parietal pleura covering the aortic arch and left pulmonary artery was then incised and these structures were directly exposed. A large patent ductus arteriosus was found, which was from 7 to 8 mm in diameter and from 5 to 6 mm in length. A palpating finger placed on the heart disclosed a continuous and very vibrant thrill over the entire organ, which was increasingly prominent as the finger reached up over the pulmonary artery. A sterile stethoscope was employed and an extremely loud continuous murmur was heard over the entire heart. When the stethoscope was placed on the pulmonary artery, there was an almost deafening, continuous roar, sounding much like a large volume of steam escaping in a closed room.

A number 8 braided silk tie was placed around the ductus with an aneurysm needle, and the vessel was temporarily occluded for a three minute observation period. During this time the blood pressure rose from 110/35 to 125/90. Since there was no embarrassment of the circulation, it was decided to ligate the ductus permanently. The ductus was too short to tie double and divide, so that ligation alone was resorted to. When the thread was drawn up tight the thrill completely disappeared. The chest was closed, the lung being reexpanded with positive pressure anesthesia just prior to placing the last stitch in the intercostal muscles.

**Postoperative Course**—The child underwent the operative procedure exceedingly well and showed no signs of shock. Prior to operation blood had been taken from a donor in order to have it ready whenever needed, but the patient's condition was so good that it was not given. There was only mild discomfort on the afternoon of the day of operation, and on the following morning the child was allowed to sit up in a chair. By the third day she was walking about the ward. When the skin sutures were removed on the seventh day the wound was well healed, but because of the interest in the case the child was detained in the hospital until the thirteenth day. After the dressing was removed and the chest could be examined adequately the thrill had completely disappeared; there was a faint systolic murmur in the left third interspace which was not transmitted over the precordium, and no murmur could be heard in the axilla, in the neck or over the back. The daily blood pressures which had been taken prior to operation and subsequent thereto showed a striking change in the diastolic levels, as is shown by the accompanying chart. The average of the daily pressures prior to operation had been 114 systolic and 38 diastolic as contrasted with a postoperative daily average of 108 systolic and 80 diastolic.

## SUMMARY

A girl aged 7½ years had a known patency of the ductus arteriosus and beginning cardiac hypertrophy. In the hope of preventing subsequent bacterial endarteritis and with the immediate purpose of reducing the work of the heart caused by the shunt between the aorta and the pulmonary artery, the patent ductus was surgically explored and ligated. The child stood the operative procedure exceedingly well. The most objective finding, which indicated that the serious loss of blood from the aorta into the pulmonary artery had been arrested by operation, was a comparison of the pre-operative and postoperative levels of the diastolic blood pressure. Prior to operation the daily blood pressure showed an average diastolic level of 38 mm of mercury as compared with a postoperative diastolic level of 80 mm of mercury. This is the first patient in whom a patent ductus arteriosus has been successfully ligated.

## Clinical Notes, Suggestions and New Instruments

## SULFANILAMIDE THERAPY IN ACTINOMYCOSIS

EDWIN M. MILLER, M.D. AND EGBERT H. FELL, M.D.  
CHICAGO

As the experience with sulfanilamide enlarges it becomes increasingly apparent that its usefulness covers a wide field. To the long list of diseases favorably affected by its administration has recently been added actinomycosis. Oliver Walker<sup>1</sup> of Liverpool reported a clinical cure of actinomycosis of the lower part of the abdomen in a man aged 23 in whom the disease developed after an operation for ruptured appendix. Compound solution of iodine and potassium iodide had been given for a brief period, without apparent benefit. Sulfanilamide was then employed in 15 gram (1 Gm) doses by mouth three times a day for five days, at the end of which time a definite diminution in the discharge was observed and a disappearance of the sulfur granules was noted. So striking was the improvement that after an interval of ten days sulfanilamide therapy was resumed in the same doses for five more days. When the patient was seen at the end of three months the abdominal wound was entirely healed and the general condition excellent.

The experience which we have to report has to do with an 11 year old white boy who was admitted to the children's surgical ward of the Cook County Hospital Oct 19, 1937. There was a tender inflammatory mass the size of an orange in the middle of the lower part of the abdomen between the umbilicus and the symphysis. The temperature was 101 F and the white blood cell count 14,100. The urine was normal. At first glance it seemed probable that the process was either an appendicular abscess or an infected cyst of the urachus. The swelling had been present for about one week, was associated with a loss of several pounds and had followed a rather prolonged period of difficulty in urination. There was nothing suggestive of an attack of appendicitis. Catheterization did not affect the size or shape of this swelling, although a cystogram seemed to indicate an extramural mass causing pressure on the dome of the bladder. Hot dressings were applied for several days, the skin became more reddened, fluctuation developed and the process pointed at the umbilicus, where spontaneous opening occurred October 29. Eleven days later an incision for better drainage was made over the center of the mass by Dr. Gatewood, and several ounces of thick pus was liberated. The wall was thick and the character of the discharge strongly suggested actinomycosis. After this suspicion had been confirmed by microscopic examination of the granules we were able to elicit from the patient the fact that during the summer months of 1937 he had been in the habit of plowing a good deal in the fields and would often chew bits of grass hay and straw.

All the well known methods of treating actinomycosis were immediately begun. Seven grams (0.45 Gm) of thymol and potassium iodide were given once each day. To the surface of the wound a 10 per cent solution of thymol in cottonseed oil was applied twice daily. Roentgen therapy was started November 19 and continued for four months, sixteen treatments being given at intervals of four to six days. The potassium iodide was gradually increased to 20 grains (1.3 Gm) three times a day. During this regimen he became progressively worse. His temperature ranged between 101 and 102 F, he rapidly lost weight and the process in the lower part of the abdomen became larger and extended toward the right where a new sinus opened just medial to the anterior superior spine. It seemed apparent that if the course of the disease did not change a fatal termination was almost certain. For this reason, purely on an empirical basis, the use of sulfanilamide was begun (Jan 18, 1938), 10 grains (0.65 Gm) being used by mouth three times a day, in addition to the other medication. Almost coincident with this change in therapy, in fact within a week's time, an improvement in the boy's condition was observed. The mass in the lower part of the abdomen gradually became smaller and softer, and the amount of discharge diminished. The patient's appetite returned, he began to pick up weight and his general appearance rapidly improved. By March 25, when he was discharged from the hospital (all medication except sulfanilamide having been stopped) he had gained 10 pounds (4.5 Kg), he was eating well, the mass in the lower part of the abdomen was becoming steadily smaller, and little drainage was present.

The boy has returned frequently to the outpatient clinic for observation. By July 18 the wound at the midline had entirely healed, although a new sinus opening of two weeks' duration in the left lower quadrant was discharging a small amount of pus. August 29 this opening also had closed and on October 1 all wounds were entirely healed. He had gained over 20 pounds (9 Kg) and was eating normally and going to school. When last seen, Nov 16, 1938 and shown at a clinic for alumni of the Cook County Hospital, the boy proudly stated that he weighed over 100 pounds (45 Kg). He was certainly the picture of robust health and showed no ill effects from the continuous taking of sulfanilamide for about ten months.

The evidence in this case leads us to believe that the agent responsible for the improvement and apparent clinical cure of the actinomycosis was the sulfanilamide, because the favorable change in the course of the disease was coincident with its use.

## INEFFECTIVENESS OF SULFANILAMIDE IN RABIES FROM VACCINATED DOGS

BENJAMIN F. HART, M.D. AND ELWIN EVANS, M.D.  
WINTER PARK, FLA.

A white man aged 41, seen because of a mild digestive upset with vomiting and a generalized headache of twenty-four hours duration, strangled when he attempted to drink cold water. He stated that he had been bitten on the upper lip twenty-two days before the onset of symptoms by a neighbor's dog while attempting to retrieve his own dog during a fight in which his dog also was bitten. Since both dogs had been vaccinated against rabies six months previously by the single injection method, he did not consult a physician. The neighbor's dog was reported to have been restless for several days. It was confined but escaped and was struck by an automobile. It died, supposedly from injuries two days after biting the patient. The patient's dog became ill two weeks after the fight and died three days later. Neither dog's head was submitted to the state laboratory for examination for rabies.

The patient had a temperature of 101 F and hyperactive reflexes. He was talkative and apprehensive. Although he could swallow warm water without difficulty, cold water caused spasm of the throat muscles. When he was offered a glass of cold water he reached for it but suddenly exclaimed "I can't do it" and buried his face in a pillow. No abnormality of the throat was found. A smear of material from the throat was negative. The urine showed a trace of albumin and a heavy sediment of amorphous urates but was otherwise normal. The red cell count was 4,700,000 and the white cell count 9,300. The Schilling differential count showed a shift to the left in spite

<sup>1</sup> Walker, Oliver. Sulfanilamide in the Treatment of Actinomycosis. *Lancet* 1: 1219 (Mar. 8) 1938.

of the mild leukocytosis, as evidenced by from 8 to 10 stab cells per hundred leukocytes

After removal to a hospital, the patient became more nervous and could not swallow even saliva, which drooled from his mouth in quantities sufficient to wet his pillow and keep an attendant busy wiping his face. Nervous excitability increased rapidly. Sedatives were given in increasing amounts, in spite of which he did not sleep or rest and it became necessary to shackle him in bed. In twenty-four hours he received a total of 12 grains (0.8 Gm) of pentobarbital sodium rectally, 10 grains (0.6 Gm) of soluble phenobarbital intramuscularly, 60 grains (4 Gm) of chloral hydrate rectally, 1 grain (0.06 Gm) of morphine intramuscularly and 2,000 cc of 5 per cent dextrose in saline solution subcutaneously.

Since there is no known specific drug for clinically developed rabies, sulfanilamide (neoprontosil) was tried. He was given 20 grains (1.3 Gm) intramuscularly every two hours for three doses and then every four hours until a total of 140 grains (9 Gm) had been administered. His temperature continued to rise steadily for sixteen hours, reaching 105 F rectally. He then passed into the paralytic stage, the temperature dropped to 100.4 F rectally and he died six and one half hours later.

CONCLUSIONS

- 1 The single inoculation method of rabies vaccination is unreliable and should not be depended on.
  - 2 Sulfanilamide (neoprontosil) does not seem to alter the progress of the disease in any way.
- 226 East Park Avenue

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT:  
THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION FOR THE VALUE OF ASSISTANCE RENDERED IN THE PREPARATION OF THIS REPORT BY DRs C. C. BUNCH, GEORGE M. COATES, LEF. W. DEAN, EDMUND P. FOWLER, AUSTIN A. HAYDEN, ISAAC H. JONES, DOUGLAS MACFARLAN, HORACE NEWHART, BURT R. SHURLY AND WILLIAM P. WHEAT.

HOWARD A. CARTER, Secretary

MINIMUM REQUIREMENTS FOR  
ACCEPTABLE AUDIOMETERS<sup>1</sup>

- 1 Audiometers shall produce vibrations at frequencies within hearing range (approximately 128 to at least 8,192 cycles per second).
  - (a) They shall be equipped for testing both air and bone conduction.
- 2 Frequencies. (a) Fixed or continuous frequencies from 128 to 8,192 cycles per second. If discrete frequency steps are provided, the tones shall be 128, 256, 512, 1,024, 2,048, 4,096, 8,192 cycles per second. Numerical annotations to be used to designate pitch.
  - (b) The frequency of any test tone shall remain within  $\pm 5$  per cent of the designated value under the manufacturer's specified or indicated operating conditions. Dials shall be marked so that frequencies may be identified readily.
- 3 Attenuation. Audiometers shall be calibrated in decibels, with 5 decibels per step or less. In no case should more than 5 decibel steps integral be used. Tolerances limits to be within  $\pm 1\frac{1}{2}$  decibels per 5 decibel steps and  $\pm 5$  decibels cumulative at any portion of the intensity range calibrated in a room free from extraneous noises. Dials shall be easily read. The term "percentage hearing" shall not be used on dial or charts. Hearing losses shall be reported in decibels loss.
- 4 Range of intensity (air conduction only). The intensity range of the test tones above the normal threshold shall be at least that as follows:

Test Tone Cycles/Sec	Intensity Range Decibels
128	60
256	80
512	85
1,024	90
2,048	90
4,096	90
8,192	90

<sup>1</sup> A clinical audiometer is an instrument for measuring the acuity and range of hearing.

5 Wave form. The purity of tone in the air conduction receiver shall be such that the harmonics at any particular frequency shall be at a level not less than 25 decibels as measured on the closed coupler artificial ear of from 4 to 5 cubic cm in volume, except for discrete frequency of 128, the harmonics shall be at a level not less than 20 decibels.

6 Extraneous noises

- (a) The level above threshold of the sound (for normal hearing people) caused by line noises (hum and commutator ripple) and all other instrument noises shall be at least 60 decibels below the level of the test tone for frequencies of 1,024 cycles per second and higher frequencies, and at least 40 decibels below the level of the test tone for frequencies below 1,024 per second.
- (b) A bone conduction receiver shall be so constructed that it does not produce sound in the air to such an extent that the sound reaching the tympanum through the auditory meatus could influence the validity of the bone conduction measurement. When the bone conduction receiver is placed in approximately the same position as is used in testing bone conduction but is held just off the head instead of in contact, the level of the sound reaching the tympanum shall be at all frequencies at least 5 decibels below the level which the receiver generates by bone conduction when in contact with the head, as judged by a normal ear.

7 Power supply. Either alternating or direct current or battery.

8 Ruggedness of construction. Audiometers shall stand reasonable usage. Employment of readily obtainable and replaceable parts is required.

9 Uniformity in calibration. Audiometers shall be calibrated thus: Intensity in decibels and frequency in number of vibrations per second.

10 Air conduction receiver calibration

NOTE.—While the responsibility for meeting the following requirements is primarily that of the manufacturer, it is recognized that the apparatus necessary for calibration is of somewhat elaborate and special character and it is expected that there will be available central testing agencies acceptable to the Council on Physical Therapy to undertake the calibration of audiometers for those manufacturers who are not in a position directly to equip themselves.

The following method shall be employed for the calibration of audiometer receivers:

- (a) Suitable receivers having permanent characteristics shall be used to determine the threshold of hearing of a large group of normal hearing people in a room free from extraneous noise. The electrical input required to elicit average normal threshold will then be known.
- (b) The calibration of the receiver shall then be transferred to a suitable artificial ear.
- (c) Receivers, having permanent characteristics, may be submitted by audiometer manufacturers for calibration by comparison with the primary standards on the artificial ear.

11 Audiogram or auditory chart. An audiogram blank shall use the same base line for bone conduction results as for air conduction results. The chart shall be as simple as possible. The coordinates of the chart shall be some appropriate number of decibels and octaves or fractions of an octave. In order that the chart may present a suitable visual impression there shall be a ratio of 1 to 2 between the dimension of a 10 decibel step and that of an octave step.

12 Definition of threshold of hearing. The American Tentative Standard Acoustical Terminology defines the normal threshold of audibility as the modal value of the thresholds of audibility of a large number of normal ears of persons in the age group from 18 to 30 years. For purposes of recording, the threshold of audibility at any frequency is the audiometer setting corresponding to the lowest intensity at which the person being tested indicates that he hears the tone more than half of the number of times that it is presented to him.

13 Marketing and advertising. Rules of the Council on Physical Therapy shall be adhered to by manufacturers of acceptable audiometers.

### NEW AND NONOFFICIAL REMEDIES

THE COUNCIL PUBLISHED A STATUS REPORT ON SULFANILAMIDE (THE JOURNAL MAY 29 1937 PAGE 1888) THE DRUG WAS LATER ACCEPTED AND A STATEMENT OF ACTIONS AND USES AND OF DOSAGE APPEARED IN THE JOURNAL JULY 11 1937 PAGE 358 A REVISED STATEMENT WAS PUBLISHED OCT 30 1937 PAGE 1454 THE ENORMOUS AMOUNT OF WORK WHICH HAS BEEN DONE WITH THE USE OF THIS PRODUCT WARRANTS A SECOND REVISION OF THE ARTICLE THE COUNCIL AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE AND NOTED INCLUSION IN NEW AND NONOFFICIAL REMEDIES IN 1939 IN PREPARING THIS STATEMENT THE COUNCIL HAD THE COLLABORATION OF DR JOHN S LOCKWOOD DR PERRIN LONG DR W W PALMER AND HIS ASSOCIATES AS WELL AS THE AID OF THE REFEREE AND OTHER MEMBERS OF THE COUNCIL AND THEIR CONSULTANTS  
PAUL NICHOLAS LEECH Secretary

**SULFANILAMIDE** (See New and Nonofficial Remedies, 1938, p 450)

**Actions and Uses**—Originally it was reported that sulfanilamide acts against Lancefield's group A strains of hemolytic streptococcus by virtue of an apparently specific effect on these organisms. More recent clinical evidence suggests that the action of this chemical may affect other organisms, especially certain gram-negative cocci. The evidence suggests that its action may be antibacterial. Experimental evidence indicates that at least one action of sulfanilamide (and possibly the only one of importance) is to render serum, spinal fluid, urine and other tissue fluids unfavorable as mediums for supporting the active multiplication of susceptible bacteria. In consequence, tissue invasion by these organisms may be prevented, production of toxic substances reduced, and the antibacterial mechanisms of the host are permitted to complete the recovery from infection.

Sulfanilamide has been used primarily in infections due to beta-hemolytic streptococci, especially in the treatment of puerperal fever, erysipelas, hemolytic streptococcus septicemia, streptococcal sore throat, surgical infections with hemolytic streptococcus, and in the prevention or treatment of complications of these diseases—notably streptococcal meningitis, peritonitis and suppurative arthritis. Present studies indicate that this drug is useful in the treatment of gonococcal infections. In some cases the results have been most striking while in others the drug has not proved especially efficacious. In this connection it is well to note that the reactions following the administration of the drug are at least occasionally of a serious nature (see below). It has also been used in the treatment of gonorrheal vulvovaginitis in young girls, but recovery from the condition has not always been permanent with this agent. The literature also indicated usefulness in meningococcal infections and possibly gas bacillus infections. It must be remembered however that, because of the extensive application of this relatively new therapeutic agent, its use in these conditions requires caution and careful observation. This is especially true in view of the reactions which are discussed in the following paragraph. The evidence is incomplete at the present time for further consideration of the possible usefulness of this drug in infections by *Bacterium coli*, *Bacterium typhosum* and paratyphosum A and B. Several clinical reports have been published which suggest that *Brucella* infections and trachoma may respond to sulfanilamide therapy but it is not known whether all varieties of these diseases are susceptible. Certain infections of the urinary tract, notably those due to *B. coli*, have responded satisfactorily to sulfanilamide therapy, perhaps because of the high concentration of the drug in the urine. There is some indication that it is useful in pneumonia due to type III pneumococci.

**Toxicity**—No patient should be treated with sulfanilamide unless arrangements are made for daily attention by a physician. This is because of the possibility of serious toxic effects, which, while not frequent are somewhat unpredictable in their occurrence and presumably have as their basis a peculiar idiosyncrasy. Many patients receiving sulfanilamide will show some degree of development of a slate gray type of cyanosis first apparent in the lips and nail beds but later suffusing the entire body. The exact nature of this cyanosis is unknown but it is not in the opinion of most observers, a serious complication and its development in a patient with a serious infection is not an imperative indication for cessation of therapy. The dangerous complications of sulfanilamide therapy are hemolytic anemia, jaundice and agranulocytosis, and sometimes these reactions occur after relatively low dosage. Frequent estimation of the red and white blood cells and hemoglobin is essential for safe use of the drug because if these complications are recognized early the use of transfusions and stopping the drug will usually result in prompt improvement. The drug produces fever with or without cutaneous rashes in certain individuals but such a drug fever usually does not develop until after several days of therapy. It has been

claimed that sulfanilamide induces acidosis and because of this the simultaneous use of sodium bicarbonate has been recommended. Magnesium sulfate should be avoided in patients receiving sulfanilamide because the development of sulfhemoglobinemia, as contrasted to the usual type of cyanosis, has been related by some observers to concurrent magnesium sulfate therapy. It should not be prescribed concurrently with other drugs without full knowledge of possible ill effects such as are encountered, for example, with magnesium sulfate.

**Dosage**—The dose of sulfanilamide in adults in cases of serious infection is about 1 Gm (15 grains) every four hours for forty-eight hours and then from 0.4 Gm (7½ grains) to 0.66 Gm (10 grains) every four hours thereafter. It is usually advisable to continue therapy for a few days after clinical recovery in order to avoid relapse (and in a case of gonorrhea for a minimum of two weeks). Infants will tolerate from one third to one half the adult dose and children from one half to three fourths of the adult dose. Patients who cannot take the drug by mouth may be given subcutaneous injections of a 0.8 per cent solution of sulfanilamide made by adding 8 Gm of pure sulfanilamide crystals to a liter of warm physiologic solution of sodium chloride or 1 per cent sodium chloride solution or, better still, ½ molar sodium lactate solution. The same total dosage may be employed for parenteral as for oral administration, but the injections should be given at six to eight hour intervals. In less serious infections, where no threat to life exists, a lower dosage of from 3 to 4 Gm daily (in adults) is to be recommended, without the larger initial dosage.

### CEROPHYL

**Manufacturer**—Cerophyl Laboratories (Division of American Dairies, Inc.), Kansas City, Mo

**Description**—Dried, powdered mixture of young leaves of wheat, oats and barley, selected and blended to maintain the minimum vitamin potency declared on the package label.

**Manufacture**—The cereals are grown on soil fertilized to produce plants of high mineral and vitamin content. The young rapidly growing leaves are harvested just before they joint by machinery especially designed to prevent the leaves coming in contact with the ground after cutting. No toxic spray materials are used. The method of cultivation precludes contamination with weeds. The freshly harvested leaves are immediately cut into short lengths and dehydrated. Hot flue gas of minimum oxygen content is drawn from a gas furnace through the drying chamber at an initial temperature of between approximately 800 and 900 C. The high initial temperature, which is quickly reduced by the evaporation of moisture from the grass, serves as a flash pasteurization of the surface of the leaves. The entire process of drying requires approximately sixty seconds. The dried material leaves the drier at a temperature of approximately 120 C. The dehydrated leaves are mechanically cleaned, pulverized, stored at -18 C, and packed in hermetically sealed cans under nitrogen.

**Analysis** (submitted by manufacturer)—Moisture 8%, total solids 92%, ash 12%, fat (ether extract) 5%, protein (N × 6.25) 25%, reducing sugars (before hydrolysis) 1.6%, reducing sugars (after hydrolysis) 11.3%, carbohydrate other than crude fiber (by difference) 35%, oxalic acid 0.06%, calcium (Ca) 0.5%, phosphorus (P) 0.5%, magnesium (Mg) 0.2%, potassium (K) 0.5%, sodium (Na) 0.2%, iron (Fe) 0.06%, manganese (Mn) 0.005%, copper (Cu) 0.001%, cobalt (Co) 0.0001%.

**Calories**—2.85 per gram

**Vitamins**—Carotene (provitamin A) (chemical analysis, Peterson modification of the Hart and Gilbert method) 0.5 mg per gram, vitamin B<sub>1</sub> (biologic assay) 3 international units per gram, vitamin G (riboflavin) (biologic and chemical assay) 30 micrograms per gram, vitamin C (chemical titration) 4 mg equivalent to 80 international units per gram. Biologic assay also shows the product to be a rich source of vitamin K and of the grass juice factor.

## THE ADVISORY COUNCIL ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

At the Annual Congress on Medical Education and Licensure held in Chicago in 1938, a proposal was made by Willard C. Rappleye, chairman of the Advisory Board for Medical Specialties, for the development of a "national council on medical education, licensure and hospitals" made up of representatives of the universities, medical schools, hospitals, practicing profession, specialty boards, state licensing bodies and public health agencies. In connection with this proposal, Dr. Rappleye said, "There are indications that the government may be urged or expected in one form or another to increase more than at present its financial support of medical care, teaching and research. It is important that the profession create in advance an agency for assisting in such a possibility and for making constructive suggestions as to how such activities can best be developed." During the ensuing period Dr. Rappleye has appeared before various organizations of specialists in the field of medicine and has had endorsement in principle at least of this project from some of these organizations. In discussions of this proposal it was suggested that such a movement might divorce from the medical profession its right to determine for itself its relationship to governmental activity in medical practice, delegating that function rather to this super council.

At this year's Annual Congress on Medical Education and Licensure, held in Chicago February 13 and 14 under the auspices of the Council on Medical Education and Hospitals of the American Medical Association, this proposal was advanced in a new form, now being named the Advisory Council on Medical Education, Licensure and Hospitals. Dr. Rappleye is reported to have stated that it is not now anticipated that there will be any governmental association with or support of this project. It is also stated that this council is to function purely as an advisory body for the hearing of

various problems of mutual concern to those represented in the council. It is proposed that this council shall be created with the following representation:

Association of American Medical Colleges	3
American Medical Association	3
American Hospital Association	3
Federation of State Medical Boards of the U S A	3
Advisory Board for Medical Specialties	1
National Board of Medical Examiners	2
American College of Surgeons	2
American College of Physicians	1
American Public Health Association	1
The Catholic Hospital Association	1
American Association for the Advancement of Science	1
Section A	2
Association of American Universities	2
	25

At a meeting of the Council on Medical Education and Hospitals held on February 11, that council decided to recommend to the House of Delegates that such participation be approved, leaving to the House of Delegates of the American Medical Association the decision as to whether or not the American Medical Association will participate through the Council. According to the By-Laws of the American Medical Association "no memorial, resolution, or opinion of any character whatever shall be issued in the name of the American Medical Association unless it has been approved by the House of Delegates." This by-law obviously would limit definitely any action which representatives of the Council on Medical Education and Hospitals could take as participants in the proposed Advisory Council.

On February 14 the Board of Trustees of the American Medical Association held a conference with the directors and the representatives of the American Hospital Association, the Catholic Hospital Association and the American Protestant Hospital Association looking toward mutual consideration of problems in the field of the hospital and of medical practice. In this conference the following resolution was prepared and adopted by the representatives of the Hospital Organizations:

1 The representatives of the American Hospital Association, the Catholic Hospital Association and the American Protestant Hospital Association here present desire to express to the Board of Trustees of the American Medical Association their confidence in the leadership of the medical profession in furthering the excellence of medical service and in aiding the solution of problems of the distribution and provision of medical care.

A second resolution was adopted by the joint meeting:

2 It is moved that the following be the sense of this meeting: This gathering of the Trustees of the American Medical Association and of representatives of the American Hospital Association, the Catholic Hospital Association and the American Protestant Hospital Association express their gratification on the unanimity of opinion developed concerning many phases of the health problems of the Nation achieved by mutual discussion. It is recommended to the American Medical Association, the American Hospital Association, the Catholic Hospital Association and the American Protestant Hospital Association that such joint meetings of their representatives be held for the consideration of problems of mutual concern.

It is proposed, further, that the Board of Trustees of the American Medical Association shall hold in the near future conferences with the authorized representatives

of other organizations in the medical field so as to bring about greater coordination between the activities of the American Medical Association, representing the entire medical profession of the United States, and the special organizations in the field of medical practice. No doubt by such mutual conferences the desired coordination among the practicing medical profession, including the medical specialties, and all the organizations auxiliary to medical practice may become effective.

### THE PROBLEM OF THE REFUGEE PHYSICIAN

In the Organization Section in this issue of *THE JOURNAL* appear statistics collected from various federal governmental agencies as to the number of physicians coming to the United States from foreign countries during the years since 1930. On September 17, 1938, *THE JOURNAL* called attention editorially to the fact that the scope of this problem is definitely limited by several factors: the quotas established by our laws regulating immigration, the total number of physicians likely to be eliminated from Germany and other central European countries, the ages of these physicians, and the opportunities available to them for securing a livelihood in the United States. Unfortunately there are publications, political groups and subsidized agencies in this country which are endeavoring to make prestige and favor for themselves by stirring the motives of selfishness, prejudice and hatred among American doctors. In *THE JOURNAL*, February 11, six distinguished leaders of American medicine urged the medical profession to cooperate with the special committees that have been set up in New York and Boston for helping in this situation. The committees specifically concerned with the problem of the refugee who is a physician are:

Emergency Committee in Aid of Displaced Foreign Physicians, 59 East Fifty-Seventh Street, New York, Dr. Emanuel Libman chairman, Dr. Laurence Farmer executive secretary. This nonsectarian committee deals with a select and small number of prominent scientists for whom positions are found in the field of medicine for research and study.

National Coordinating Committee for Aid to Refugees and Emigrants Coming from Germany, 165 West Forty-Sixth Street, New York, Joseph P. Chamberlain chairman, Miss Cecilia Razovsky executive director. This committee coordinates the activities of the major organizations working in this field.

Boston Committee on Medical Emigres, 114 Riverway, Boston, Dr. David L. Edsall chairman. (The Problem of the Refugee Physician, *THE JOURNAL*, February 11, p. 570).

Various suggestions have come to the American Medical Association urging the establishment of a special committee to handle this problem. Thus far the only action taken by the House of Delegates has been a recommendation to the state boards of medical registration that in the case of foreigners graduates of foreign institutions citizenship be required for license to practice. Every physician knows the right to regu-

late the practice of medicine rests with the individual states. As the letter recently published points out, "in the field of general practice and in the specialties also numerous openings exist for which it is difficult to find qualified American physicians, for example, poorly paid full-time positions and practices in rural communities." If any of the committees can undertake to make a survey to locate such openings, a certain number of the refugees can be absorbed with a minimum amount of disturbance of the rights of American physicians.

The chief difficulties that have arisen in this situation result from the fact that some of the refugees are poorly trained or of low ethical standing, that some find it difficult to adapt themselves to American ways in the practice of medicine, and that many tend to settle in large cities already overcrowded with physicians. Certainly a physician who is poorly trained or of low ethical standing should not be permitted to practice anywhere. Perhaps the difficulties of adaptation can be overcome by well planned instruction. Only the coordinating committees already mentioned, or groups of a similar character, can aid in solving properly the problem of suitable distribution of the refugees to places where they may be useful rather than a foreign body setting up irritation and forcing extrusion.

### RECENT INVESTIGATIONS ON ANTIBODIES

The nature and formation of antibodies constitute a fundamental aspect of immunology. Under the leadership of Belak of Budapest, numerous studies of the relationship of neurologic integration to antibody production have been carried on at the Institute for General Pathology.<sup>1</sup> There it has been shown that stimulation of the parasympathetic by therapeutic doses of pilocarpine increased the titer of specific agglutinins in vaccine therapy. Therapeutic doses of thyroxine or epinephrine, on the other hand, reduced such specific agglutinins.

Illenzy and Borsak<sup>2</sup> of Budapest have recently suggested the plausible hypothesis that the antibody titer is a function of the vegetative nervous system. This hypothesis is an outgrowth of the attack on the theory of preformed antibodies and the championing of the belief that antibodies are new chemical products synthesized by the combined action of reticulo-endothelial cells and other tissues of internal secretion. Under the latter theory widely separated immunogenic functions could become integrated through the nervous system. These investigators tested the effects of therapeutic stimulation and depression of both the sympathetic and the parasympathetic system. Pilocarpine was selected as the parasympathetic stimulant, with atropine as the depres-

<sup>1</sup> Belak S, Saghy J and Cseresznyes L. *Ztschr f d ge exper Med* 52: 559 1926. Belak S and Cseresznyes L. *ibid* pp 567-572. Belak S and von Steigler J. *ibid* 75: 443 1931. Belak S and Szabo, D. *ibid* p 449.

<sup>2</sup> Illenzy, Andras and Jorak Ladislaus. *Zt chr f Immunitat* for ch 19: 79 (Oct) 1938.

sant Ephedrine was used as the sympathetic stimulant. They injected rabbits intravenously with heterologous erythrocytes and obtained an average antiserum yield in hemolytic titer of about 14,000. Rabbits given a subcutaneous injection of 1 mg of pilocarpine hydrochloride from five to ten minutes before immunization yielded an average hemolytic titer of approximately 30,000. A 100 per cent increase in the yield of specific hemolysins, therefore, was attributed to therapeutic stimulation of the parasympathetic. In a second series of tests the average control yield of hemolysins (20,000) was reduced 20 per cent by a previous subcutaneous injection with 0.375 mg of atropine sulfate and reduced at least 70 per cent by previous subcutaneous injection with 1 cc of 1 per cent solution of ephedrine sulfate. Parasympathetic paralysis and sympathetic stimulation, therefore, both reduce the specific antibody yield.

These observations led the Hungarian investigators to assume that the antibody titer is a function of the vegetative tonus at the time of immunization. It has not yet been determined whether there are qualitative as well as quantitative changes in specific antibody yield as determined by initial vegetative tonus. Nevertheless a reasonable explanation of these observations would be that vegetative tonus at the time of intravenous injection of formed antigens determines localized distribution to antibody-forming tissues.

The recent demonstration by Goreczky and Ludany,<sup>3</sup> also of Budapest, that blood drawn from the splenic sinuses is richer in protective antibodies than the systemic blood is additionally suggestive of the mechanism of local tissue immunity. Biochemists have long recognized that the relatively stagnant blood of the spleen is richer in potassium, phosphorus, cholesterol, albumin, euglobulin and noncoagulable nitrogen than carotid blood but poorer in pseudoglobulin. These differences nevertheless have been generally supposed to be due to the local destruction of erythrocytes. The investigators, however, have for the first time applied quantitative immunochemical techniques to the problem of splenic immunity. They found, for example, that in dogs opsonins are from two to ten times higher in titer in splenic sinus blood than in the general circulation and that bacteriolysins are at least 30 per cent greater in amount. (For these titrations B typhi, B anthracis and staphylococcus were used.) Possibly these investigations will lead to a recrudescence of interest in the supposedly obsolete hypothesis which pictured the spleen as the sole source of specific antibodies. While it is doubtful that this theory can be renewed in its entirety, the local splenic synthesis of antibodies would account for the rarity of infectious metastases in this organ and for reduced bacterial resistance following splenectomy. Further studies along these lines will doubtless be productive of much information which may prove ultimately of great practical value.

## Current Comment

### NO CONGRESSIONAL DEFINITION OF NATUROPATHY

In 1933, naturopaths in Iowa sought special privileges from the legislature in the form of a law to enable them to ply their trade without possessing qualifications adequate to protect the public health. Their bill, which failed of enactment, proposed to define naturopathy "according to the definition of naturopathy, enacted by the Congress of the United States of America and the District of Columbia." In the same year, and no doubt in other years, a self-styled "Examining Board of Naturopathic Physicians, Arizona District," incorporated under the laws of Arizona, issued so-called "certificates" to naturopaths, purporting to authorize certificants to "pursue the practice of naturopathy within the corporate powers of this association." It claimed to be acting "under the authority of the American Naturopathic Association" and "by virtue of the definition of naturopathy as set forth in and by an Act of Congress approved February 27, 1929, and verified in and by an Act of Congress approved February 7th, 1931, which Act defines naturopathy." In 1938 a petition, which the court denied, was filed in the circuit court of Jackson County, Mo., to form a corporation with various and sundry powers, including the authority to establish naturopathic schools for the training of students in naturopathy "as defined by Congress under the provisions of House Bill No. 12169 passed and approved by the Seventy-First Congress of the United States in the year 1930." Feb. 8, 1939, a bill was introduced in the legislature of North Dakota proposing to define naturopathy "as provided by an Act of Congress of 1929." There seems little reason for doubt that similar statements have been made by naturopaths at other times in other places. The fact is, the statements of naturopaths to the contrary notwithstanding, the Congress of the United States has never defined naturopathy. A Healing Arts Practice Act for the District of Columbia was approved Feb. 27, 1929, which did provide for a board of naturopathic examiners, it did not define naturopathy but authorized the Commission on Licensure to Practice the Healing Arts to do so. The definition formulated by the commission was unsatisfactory to the naturopaths and May 5, 1930, they caused to be introduced in the House of Representatives of the Seventy-First Congress a bill, H. R. 12169, to define naturopathy more broadly than it had been defined by the commission. This bill passed the House of Representatives Feb. 7, 1931. In the Senate it was referred to the Committee on the District of Columbia, where it died with the adjournment of the Seventy-First Congress. No other bill has since been considered by the Congress proposing to define naturopathy. The fact that naturopaths have apparently considered it necessary to resort to trickery to gain their objectives indicates their disbelief in the inherent merit of their cause. It should be an added reason, in any event, why their appeals should receive scant consideration.

# ORGANIZATION SECTION

## IMMIGRATION OF ALIEN IMMIGRANT PHYSICIANS

According to material obtained through government agencies, alien immigrants describing themselves as physicians have entered the United States during each fiscal year since June 30, 1930, as shown in table 1

Neither the foregoing figures nor those that follow include alien physicians who entered the United States as tourists and whose stay is accordingly limited. No

TABLE 1—Annual Immigration of Alien Physicians

Fiscal Year Ended June 30	From All Countries	From Germany, Austria	Physicians Listed as Jewish
1931	329	16	38
1932	259	23	34
1933	147	8	41
1934	373	166	163
1935	304	104	137
1936	462	253	273
1937	533	286	319
1938	738	365	475

During the four months July, August, September and October 1938, 482 alien immigrants who described themselves as physicians entered the United States. Of these 390 were Jewish physicians.

evidence has been found to show that any order has been issued undertaking to extend the time during which such alien tourist physicians may remain in this country. No evidence has been found to show that alien physicians find their way into the United States for permanent residence by entering through countries other than those in which they respectively are nationals, as, for instance, German physicians entering the United States by way of some country in South America.

As between the fiscal year ended June 30, 1937, and the fiscal year ended June 30, 1938, the outstanding changes in the numbers of immigrant physicians entering the United States are shown in table 2.

TABLE 2—Increase in Immigration Within Two Years

From	Fiscal Year Ended June 30 1937	Fiscal Year Ended June 30 1938
Germany, Austria	286	365
Italy	14	26
Switzerland	11	25
Canada	79	107

Immigrant physicians from Asia increased from thirteen in 1937 to thirty-three in 1938, the number arriving in the latter year coming from China, ten, India, one, Palestine, twenty and Syria, two. It does

TABLE 3—Racial Stocks Represented

	Fiscal Year Ended June 30 1937	Fiscal Year Ended June 30 1938	Four Months July, October 1938
English	31	36	11
German	98	86	43
Jewish	310	475	390
Irish	11	18	1
Hungarian	7	12	6
Scotch	10	26	10

not necessarily follow, however, that physicians arriving from those countries were not Caucasians.

In racial stocks the numbers entering were as given in table 3.

## SIGNS OF THE TIMES IN PUBLIC HEALTH

HAVEN EMERSON, M.D.  
NEW YORK

Four national professional bodies have within the past few weeks expressed opinions on the proposals of the so called National Health Conference. These four associations, of physicians, hospital administrators, health officers and dentists, independently and by the long established methods of representative and free discussion have arrived at surprisingly uniform points of view on the five proposals of the officials of the federal government which we are told will be the objective of enabling, enforcing and appropriating legislation at the next session of Congress.

We may ignore the errors of fact of social theory and of methods employed by the present federal administration to promote acceptance of its proposals. However it is obvious that the evidence on which the extravagantly phrased descriptions of the existing state of health and medical services in the United States appear to have been based are inadequate to answer the questions at issue or to carry conviction to any but a credulous lay public.

What has been published as a National Health Survey was nothing of the kind, and what was publicized as a National Health Conference was not a conference at all but a sounding board before which a hand-picked and in the main a pre-convinced group of invited guests listened to the report of a technical committee with the doubtful privilege of extemporaneous comments but no opportunity for collective consideration or adop-

tion of the slightest change in the ready-made proposals which they were assembled to endorse.

What we have before us is not a National Health Program in any rational sense of the word in that it has not been conceived on the basis of the respective needs of all parts of the nation nor has it been in any true sense nationally accepted. The five proposals do not constitute a program but proposals for expenditures to supplement and make more effective those functions long recognized and generally carried on with a large measure of success by local and state governments. And under the popular slogan of health are included features of public service which deal exclusively and properly with the sick. Public health practice is a professional specialty as rigorous in its educational disciplines and as distinct in the skills involved as are the chemical specialties in the private practice of curative medicine.

That further extensive gains in the quality and average duration of human life can be attained by the more consistent and adequate employment by civil government of the resources of sanitation and preventive medicine there can be no doubt. To describe the present state of the public health services of our country as grossly inadequate is a mischievous untruth and expresses an emotional unbalance in the thoughts and experience of the technical committee members unworthy of persons trusted with national statesmanship.

We are now in fact the possessors of better general health, are less afflicted with preventable disease, are more secure in the survival of our offspring, to maturity and have an average

expectancy of life greater than that of any population group in the history of man, comparable in size, variety of races and distribution in age, occupation and economic and climatic conditions. We are today at the very zenith of a march of progress toward national health. Never before in this or any other continent have any 130,000,000 people recorded such low death rates as will be reported in the United States for the year 1938 for all causes, for tuberculosis, typhoid, diphtheria and infant mortality. Not in our time has maternal mortality been so low, or the death rate from pneumonia.

And yet the armchair pundits in Washington tell the people of the United States that our public health services are grossly inadequate. Of course this language is used to develop dissatisfaction with the present so that people will tolerate taxation for the future.

We have not in the past awaited the sign of ready money from Washington to expand our public health services for the protection of motherhood, the infant and for childhood, but we have found always that true progress in these aspects of the application of protective medicine to women and children has been no more rapid than the spread of a convinced lay opinion of their necessity. Mere spending of money by federal grants will not bring lower sickness and death rates until the community of city, village, county or state understands and participates through its own officers and professions in the use of the knowledge of preventive medicine.

What do the four professional groups say to the proposal that public health services be expanded? They agree as to the necessity of more and better application of the science of preventive medicine for social ends through government. But they stipulate that the federal government put its own house in order and show in earnest of its good intent by following the example of Canada and England and a score of other nations in consolidating all their health services under one department, with a Secretary for Health in the national cabinet. States and local health departments are weary and bewildered by the duplicating and often conflicting proposals of unrelated bureaus and boards of federal government each with ideas, standards and money grants with strings attached for health improvement.

It takes longer than one four year presidential term, or even two, for federal agents to learn as much about the peculiarities of needs and variety of factors affecting health in the forty-eight several states as the competent officers of local government have long known. Nothing new has been proposed, only a larger grant of money aid to the states from which the money was originally taken to the detriment of their own local programs.

In the spirit of thrifty taxpayers, and with the wisdom of long experience in personal medical relationships, the professional associations warn against any such public expenditures for treatment of diseases of women and children as can best be carried on by the private relationship between doctor and patient.

The professional bodies, particularly the American Public Health Association, previously declared, and continue to hold to their belief, that the indispensable factor in any national health program is the organization of permanent full time health service under nonpolitical qualified professional direction in each unit of local government of sufficient size to support the necessary personnel.

In brief then, sound professional opinion is favorable to the granting of further federal financial aid to states for the promotion of their programs of public health through the expansion of local health organization, the federal interest and promotion to be through a single department, and services to mothers and their children to be so far as possible by the private practitioner of medicine.

Concerning the second proposal of the federal government, dealing with increase of general hospital facilities, we can with advantage note the guarded approval of those who carry the administrative and professional burdens of institutions for the care of the sick.

When and where need exists then and there additional hospitals should be built, if necessary with state and federal aid, but with this important proviso, that careful and detailed first-hand studies of each community concerned be made which

reveal that such need exists and that the hospital when built can be properly administered and maintained.

Furthermore, the American Hospital Association calls the attention of the federal government to the economy of using existing voluntary hospitals, where these are well administered and of good medical standards, instead of building new hospitals out of tax moneys to compete with those supported by voluntary contributions and earnings.

It is a matter of the greatest encouragement to find so clearly expressed the opinion of the federal officials to the effect that, in developing more adequate quantity, quality and financial support for the complete medical care of those found to be unable to meet the cost of this from their own resources, "the role of the federal government should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice."

This is the only sound way of using the resources of local and state social and governmental ideas and equipment to meet equally varied needs of different communities. Several patterns have already been used in some states and counties, the state and county medical societies taking leadership in protecting the public against commercial medical exploitation and offering such guaranty of quantity and quality of care to the sick poor as the physicians and officers of local government agree on as necessary and reasonable in cost. It may be remarked in passing that no system of payment for medical care of the indigent sick so far proposed or put into effect will equal in its cost to the taxpayers what the physicians in practically every county of the United States have been giving at the most modest schedule of charges, freely year in and year out, at their offices, and in the wards and outpatient services of hospitals and similar institutions. What the medical profession is primarily concerned with is that the community accept the burden of cost which their own wealthy patients and private philanthropy can no longer carry.

That a high quality of care has been given to the sick poor in the past is generally admitted and is attested by adequate statistical proof of the reduction in morbidity and mortality to their present low levels among such persons.

Some people will always need medical attention, but the reasons for this are not largely, if at all, the inability of these sick to pay for the cost of necessary treatment but chiefly result from ignorance, superstition and misinformation growing out of religious beliefs and faith in the promotion of advertised medicaments. That anything like one third of the sick now lack medical care or that an even larger proportion of the population are hindered from gainful employment by preventable and remediable but uncared for disease, as the peroration of the technical committee would try to persuade us with statistics and emotional publicity, is just so far from the truth that it will be forgotten by the public and by the physicians of this country who know it is not so.

It would be nearer the truth to say that catastrophic economic disorder and resultant disadvantages to the wage earner are the causes of some illness than that neglected sickness is the main factor in any substantial amount of unemployment. Probably one of the largest factors other than the worldwide breakdown of international commerce and the discrepancy between technologic increase in the capacity of industry to produce and the purchasing ability of the consumer is that sanitation and public health have saved lives and prolonged them beyond the years of optimum employment faster than industry has been able to expand its payroll. I am inclined to believe that a fair estimate of the lives saved by preventive, personal and public health services in the past thirty years in the United States would closely correspond with the number of persons now unemployed.

Three of the four professional bodies expressed frank opposition to compulsory insurance to meet the cost of medical care of sickness, what is generally and always erroneously called health insurance. The fourth, the American Public Health Association, did not endorse this and by ignoring it presumably expressed its disapproval.

It is obvious that all the most responsible professional opinion representative of the medical sciences and administrations is to the effect that, for most if not all fractions of our population

now, compulsion to participate in a federal or state scheme of insurance for personal care in sickness is undesirable.

Coupled with this is evidence of confidence in the already proved value of the many applications of organized thrift to prepay for the cost of hospital care, i. e. hospital service insurance.

Approval is expressed also for cash indemnity insurance plans intended to cover the costs of emergency or prolonged illness, and expansion of workmen's compensation to cover the cost to the individual of industrial illness. Indemnity insurance to assist persons at various income levels to meet the cost of their sickness out of their own resources is also approved in principle on a voluntary basis.

The fifth item of the federal proposals, insurance against loss of wages during sickness, has met no opposition and is endorsed by the American Medical Association with the reservation that the attending physician should not be held responsible for certification of the degree or duration of disability from illness.

It remains now for each local and state health administration to determine its own line of development in respect to those objects for which substantial grants will doubtless be provided by the traditional munificence of the taxing powers of the Congress, to be distributed to the states on certain formulas of population, wealth, sanitary need and special health hazards.

On what basis is the best application of preventive medicine to be built? Certainly on the four elements, the practicing physician, the local health departments, visiting or public health nursing, and an educated public.

The state and county medical societies and the corresponding state and local health officers agree on objectives and methods of cooperative work of a preventive nature. There are, however, two matters that will require the most thoughtful joint consideration in the immediate future. One is the threat to public health services from inclusion under the health officer of services for the indigent sick and the other is the decision whether services for the sick at taxpayers' expense shall be administered by a department of welfare under lay direction or by a medical officer devoted exclusively to this function or acting as a bureau chief within the local department of health.

Even if the county medical society achieves a satisfactory contractual relation with local government for caring for the sick poor in their homes, there will be needed administrative supervision of this work to assure approximately uniform excellence of professional services and to prevent inequality in payment for equal responsibility and skill. This will call for a physician of ability and judgment. In large cities and in communities where the indigent sick are already served by

a strongly staffed and well controlled hospital and dispensary system it may well be that the medical chief of the care of indigent sick will be independent of the health department. Already we have large cities where the charter assigns to the department of hospitals responsibility for care of all sick who are eligible for free medical care, whether in hospitals, at dispensaries or in the home. The least promising method to be proposed is to have care of the sick poor administered by physicians as subordinates in a welfare or relief organization of the local government.

Quite apart from the administrative organization that may be set up with the assistance of combined federal and state funds is the effect of this new communal sickness service on the public support of and interest in the standard functions of the department of health.

Usually in American life, prestige, public concern, publicity and political influence go where most public money is spent and the largest number of public employees are engaged. We can rest assured that money will be always appropriated for the care of the sick. The sick must be served. It has taken generations to teach our communities that investment in health is a proper object of public expenditure. The public knows that the health officer can prevent some diseases. What the public does not know is that few if any of even our best qualified health administrators, whether medical or lay, are qualified for responsibility of supervision of standards or quality in the clinical practice of curative medicine.

We must expect on the experience of other countries that, if government actually operates on any compulsory insurance scheme a considerable amount of the services for the sick for people at low income levels, the cost of medical care of these people will be largely increased, perhaps doubled by the cost of administration. We have good reason also to suspect that the quality of care will deteriorate and that the amount and duration of complaints of illness and the amount of medications used will all markedly increase.

The present cause of lack of well qualified medical care for those really needing it, and wanting it but not receiving it, is chiefly ignorance of available resources, and it would appear that such sick persons are included in not more than 5 per cent and in various samplings less than 0.5 per cent of the total population.

It is as much the duty of the medical profession to warn the public against extravagant and utopian schemes of all inclusive commercial or governmental provision of medical care with their inevitable inferiorities as it is to assure a constantly improved standard of personal services to the sick on the basis of private economic and professional relationship.

## OFFICIAL NOTES

### ANNUAL CONGRESS ON INDUSTRIAL HEALTH

*First Annual Meeting held in Chicago Jan. 9 and 10, 1939*

*(Concluded from page 647)*

DR. LEON U. GARDNER, Saranac Lake, N. Y. in the Chair

TUESDAY, JANUARY 10—AFTERNOON

#### A General Surgeon Views Industrial Surgery

DR. HARRY E. MOCK, Chicago. Industrial surgery differs in no wise from any other type of surgery. The term is a misnomer. Surgery of trauma is the correct terminology. Industrial medicine and industrial hygiene differ in no wise from any other type of medicine or of preventive medicine. Every physician, whether connected with industry or not must deal with the same type of illnesses as are found in industry. While a major portion of the occupational diseases come from industry yet the products of modern industry scattered throughout the homes, schools, offices and even our hospitals often carry the hazards of occupational diseases with them. Industrial medicine and surgery is not a specialty comparable to other specialties in the field of medicine and surgery. Rather it is the application of the best principles of medicine and surgery to a group

of people connected with a given industry. In 1917 I published the first book ever written on industrial medicine and surgery, per se. The purpose of this book was not the development of a new specialty but rather to elucidate the humanitarian part medicine could play in the preservation of the lives and limbs of the working force of any industry. Prior to 1910 many industries had company surgeons whose sole job was the care of the employees injured while at work. Too often these were only 'pot-boiling jobs' and the surgical care rendered the injured was all too inadequate. In the rapid development of modern industry in the three decades prior to that time human life was held all too cheaply. The establishment of medical departments in a large number of industries during the early years of 1900 made human conservation the firm foundation of production. With the growth of this form of medicine the field has extended into the living and home conditions of the working forces, gradually resulting in closer cooperation with the public health authorities. In fact this form of practice has become a vital factor in the nation's health.

To the politicians, who suddenly have awakened to these economic and social advancements, social security is apparently a new discovery filled with the greatest of political potentialities. The prevention of accidents, better medical and surgical care for the sick and injured employee and allied welfare movements,

giving greater security to the worker, such as profit sharing plans, mutual benefit associations, loan plans for aid in case of illness, and often pension systems, have been in vogue for many years. All were accomplished by the process of education and gradual evolution. With a few exceptions, none of these movements improving the economic and social status of the working man and woman were brought about by legislation. True, new laws have appeared on the statute books of the majority of states providing employees' compensation for injuries, control of working hours, especially for women, control of the working age for children and protection against occupational diseases, but in every instance these laws have not been thrust on the people but have been the result of the educational programs and the demands of medicine and similar groups for these needed laws. We have long since learned that the most lasting changes for good are those which are voluntarily grasped by the people. In these days of governmental legislation for great economic changes and so-called social security, those in control of the government should realize that the voluntary adoption of such changes by the people themselves is far better than paternalistic force.

The organization of the Council on Industrial Hygiene by the American Medical Association is the result of thirty years of educational work in the field of industrial medicine and surgery.

The medical centers will soon be overcrowded with specialists, and many will be forced to seek a practice in the smaller communities. Here they will lack fellow specialists to meet these emergencies, and they will be forced to become general surgeons. Traumatic cases will comprise at least a fourth of their practice. Whether their trauma cases come from the industries of that community, from the homes or from the streets they must be competent general surgeons if they are to meet the situation. The time is past when a surgeon can consider trauma cases as a side issue. Any surgeon who is bored by the treatment of injuries of whatever character should refuse to treat such cases. The treatment of trauma requires a general surgical knowledge, an alertness in diagnosis, a passion for daily detail that can last for weeks and months, and an enthusiasm for results that will be a driving force until the patient is eventually restored as far as is possible. After the emergency is met and the patient's life saved for further treatment, the wise surgeon, if the injured portion of the body warrants, will seek the aid of the specialist.

Many industries refer their injured employees to the neighborhood doctor. As the number of these cases increases, many of these doctors are forced to limit their practice more and more to the care of the ambulatory injured employee. Thus, all over the country there are a great many surgeons who are doing so-called industrial surgery. In reality, their work is minor surgery limited largely to the treatment of injuries. The proper care of these minor surgical conditions is just as important a field in surgery as is the care of the major conditions. Too often, surgeons well equipped to do this minor surgery seek, without sufficient training in general major surgery, to care for the major cases. When difficulties arise they seek aid from the specialist. Too often great human suffering and even loss of life and limbs would be prevented if the given case had been turned over earlier to the general surgeon familiar with major surgery or to the specialist. On the other hand, recognition of the principles of medical ethics in this form of surgery as regards consulting with and helping a fellow physician in the care of his patient would go far toward correcting this evil. Many of these surgeons practicing minor surgery in an industrial center are far more competent in the care of the minor case than are many of our great surgeons whose practice is limited chiefly to major surgery.

The majority of industries depend on insurance companies to pay the compensation and the hospital and surgical care for their injured employees. Many of these industries retain a personal interest in their injured, endeavoring to see that they receive the best of care and that when cured they are given a job once more. Too many industries, however, feel that they have met the situation when they pass the responsibility to the insurance company. Their interest in their injured employee ceases and his future economic independence is of

little concern to them. Certain ones of these insurance companies seek only the cheapest hospital and surgical service for these patients. But during the last twenty years one has witnessed the swing of most insurance companies from cheap, inadequate surgical service to the use of good surgeons, no matter what the cost.

The criticism is heard that the injured employee does not have free choice of his surgeon. The railroad companies and many of the great industries, recognizing that the employee's choice often results in poor service, have selected staffs of surgeons to care for their injured. The insurance companies usually will not interfere if the choice of the physician or surgeon by the injured person is good, and proper care is being given. Occasionally the employee's choice is so poor that the insurance company insists on procuring a competent surgeon. In answer to this criticism it is safe to say that today the injured workman in industry receives just as good service as and often better service than does the average individual injured in his home or on the street, who has free choice of his physician or surgeon. Unquestionably, there are many flaws and many loop-holes for abuses under the present administration of employee's compensation and the furnishing of surgical service, either by industry or by its elected insurance agency, but the injured employee is far better protected and the type of surgery he receives is far superior than was true thirty years ago.

A few outstanding surgical changes which have occurred during my years of experience in surgery of trauma are worthy of note. We have come to recognize that shock, which is present in all serious injury cases, must be treated first if deaths are to be prevented. In the field of accident prevention "safety first" has become a household slogan. "Shock first" is herewith proposed as a much needed surgical slogan. Blood transfusion, seldom done thirty years ago, is now one of the greatest life saving procedures in severe trauma accompanied with shock or hemorrhage. There are certain emergency life saving operations that must be performed at once if life is to be saved—the ruptured spleen or liver, perforations of the bowel or intestine, torn blood vessels within the neck, chest or abdomen. Here the oxygen tent, new forms of anesthesia, blood transfusions and other modern methods of keeping the patient alive while undergoing the emergency operation are aiding in saving some of the most desperate cases. Skull fractures, far more common than formerly, are not being rushed to the operating room for subtemporal decompressions as was true thirty or even ten, years ago. The operative rate in skull fractures has dropped from around 36 per cent to 10 per cent and the mortality rate from around 40 per cent to from 17 to 25 per cent. More attention is being paid to overcoming serious crippling conditions. The aftermaths of injury which formerly were considered permanently disabling are now yielding to reconstructive surgical measures aided by the proper and judicious use of physical therapy and occupational therapy. These and many other advancements in the field of traumatic surgery have been brought about to a large extent by surgeons responsible for the care of the injured in industry.

Thirty years ago, except for a few small railway surgical associations, there were no special surgical groups interested in traumatic surgery. Today there are at least twenty outstanding railway surgical associations, stimulating the interest of many of our best surgeons on the subject of trauma. There are several local and state associations, or institutes, of traumatic surgery. Today, in the great majority of cases, the injured worker receives as good surgical care as the wealthiest individual of the land. Medical schools are teaching students the principles of good traumatic surgery. Surgery of trauma is rapidly becoming one of the greatest fields of surgical endeavor.

#### MEDICAL SERVICE TO SMALL INDUSTRIAL PLANTS

##### Statement of the Problem

DRS VICTOR G. HEISER and DONALD M. SHAFER, New York.  
Out of a total of 45 million gainful workers in America it has been estimated that 15 million people are employed in commercial units of less than 500, and they are the bread-

winners for about 75 million people. In a survey of the problems of industrial hygiene in a typical industrial area in the United States it was found that the workers were exposed to fifty specified substances and conditions. Of this number about 20 per cent of the workers were exposed to carbon monoxide and about 10 per cent to emery dusts, 10 per cent to lead and the same percentage to quartz dusts. Also it was found that about 42 per cent of the workers were subjected to potential accident hazards due to unguarded machinery.

It is a general belief that the hazards of industrial poisons are present chiefly in the large companies and seldom in the small ones. We doubt that this is true because the small companies generally use the same materials as the larger companies and although in one particular plant they may not have the number of hazards that the large companies do, small industry in general uses the same substances that large industry does and consequently is exposed to the same hazards.

There is reason to believe that the individual workman in the small plant is exposed to more hazards or to the same hazard in more ways than the man in the large plant. This is ascribed to the fact that in many small plants, because of the limited number of employees, each man must carry out two or more steps in the manufacturing process. Thus he may come in contact with more than one potential poison or with the same poison in different states or manners. In neither case is he as familiar with the methods of protecting himself as is the workman in the large plant. For the number of man-hours worked, the small plant has more time loss due to industrial accidents and more frequent accidents than in the large plant. This greater loss is attributed to the lack of a medical service, to a less well organized program of accident prevention and to a want of appreciation of the cost of these losses by the small manufacturer. With this same premise holding true, it is believed that the time loss and absenteeism due to occupational disease is also greater in small factories. A number of statistical studies indicate that absenteeism due to nonoccupational accident and disease is greater in the small than in the large plant.

The problem of record keeping among the small manufacturers is one on which the whole campaign of endeavoring to bring adequate medical care to their workers is founded. There are few if any records kept among the small companies that show anything more than just the absences. There must be a test group established that will provide adequate records of absenteeism and its true causes and the results must be carefully studied to determine a method of record keeping most suitable for the small manufacturer. Because of the tremendous loss due to illnesses of from one to three days, the study of short term absenteeism must be an integral part. Some efforts are already under way to try to define the present status of absenteeism among the smaller companies. The National Industrial Conference Board is at work on such a survey.

After the small manufacturer has been convinced of the extent of loss by means of his records he will probably demand a solution for his problem. At this point we must be able to provide him with information regarding the personnel and the manner of operation of an adequate medical unit. This is the point at which the small manufacturer usually balks, because he feels that in a company the size of his there is no way in which he can afford to have adequate medical care. At present this usually results in the employment of a physician in the vicinity on an emergency basis. Almost always his choice of the physician in the first place is due to personal friendship or hearsay. Medical care of this nature seldom results in anything more than patching up an injured workman. The small manufacturer is usually definitely humanitarian and greatly concerned with the welfare of his men, but the cost of adequate medical care by the usual means is prohibitive. It has been estimated that the upper limit in the cost of medical care that the average small manufacturer can afford is about \$13.50 a man annually, and if such care is to be generally adopted it will have to start at a much lower figure. In the beginning at least the annual cost for the small manufacturer should not be over \$10 a man. The equipment necessary for a small employer to purchase must not demand a large cash outlay. Some small manufacturers have indicated

that they felt \$350 to be the most they could devote to the setting up of a medical unit.

The tremendous, complex problem brought up by the small manufacturer's need for medical care is essentially educational in nature. The small manufacturer himself must first of all learn his need for help from the establishment of comprehensive records, and then what an industrial medical service can do for him. He must be shown how it will influence the quality and quantity of his production, what it will do for his workmen, how it will affect his costs of compensation, how he can justify the additional expense to his stockholders or partners, in short, that it is not welfare work or philanthropy but 'good business.'

The National Association of Manufacturers is at present cooperating with the National Industrial Conference Board in a survey of the practices of the small industrialists. It is cooperating with state manufacturing associations in the advancement of industrial hygiene consciousness among their members. It is in contact with various trade associations in their activities to promote industrial medical care. Furthermore, many of the state departments of health and labor and the federal agencies have been visited and the value of cooperation between industry and government has been strengthened and confirmed as the best means of an equitable relationship in the advancement of the care of the worker.

The National Association of Manufacturers has prepared a pamphlet entitled "Do Good Working Conditions Pay?" written for the benefit of the manufacturer alone, addressed entirely to him, and phrased in popular language.

This educational program directed toward the manufacturer must be preceded or paralleled by education of the physician. The doctor who undertakes to care for the workmen of a factory must know the potential industrial hazards of that factory's processes and materials. He must know therapy, prevention and diagnosis, and he must know workmen. The education of the doctor so that he may serve industry in a manner of real value to industry and of real credit to his profession is I believe, part of the program of the Council on Industrial Health.

#### The Private Physician and His Occupational Disease Work

DR CAREY P. MCCORD, Detroit. Whatever may be entailed in changing industrial conditions, it is expectable that the employer will be charged with increasing responsibilities for his workers' health. At this time it is most uncertain that these increased employer responsibilities for worker health protection will lead to augmented medical facilities on the work premises or instead that the responsibility of the employer will be met indirectly through taxation, insurance contributions or related devices. However, unless great changes early appear in the conduct of either industry or medicine or in both, there are reasons to believe that the greater proportion of industrial health work will be carried out, as at present, by the general practitioner and his consultants.

When an industrial worker is injured or acquires an occupational disease at once many more problems arise than the procurement of treatment of the injury. Among others there may arise problems connected with employer liability, compensation, insurance, security of the family during the breadwinner's absence, rehabilitation, the prevention of further cases of the same injury or occupational disease. The private practitioner is often handicapped in connection with the meeting of nonmedical or semimedical problems of the injured industrial worker. The private practitioner seldom knows industrial operations practices, chemicals or exposures. He may draw worker patients from twenty-five different industrial plants. It is seldom true that this physician knows much about any of the activities carried out on the premises of any of these twenty-five plants. It may be asserted that at least one half of the spurious claims for compensation or common law suits are in part due to the unfamiliarity of the physician with industrial practice and materials. The injured workman ordinarily has his interests better served by the company physician and his consultants. The old idea that industry maintains a medical department largely to thwart the injured workman is fantastic. Industry regards its trained workers as its most

valuable asset and is far more concerned in their well being than any casually selected physician. While a definite need exists for the highly skilled industrial physician, working on the plant premises, only a low percentage of the plants are of such size as to warrant his services as part of the industrial organization. In these tens of thousands of plants the services of the private practitioner are valuable, but if he is to be accepted as a definite ally of industry and its workers he must accept responsibility for many other types of activities than the amputation of fingers, the suturing of wounds, the treatment of burns, and so on. There is a great clamor from industry and its workers for a better understanding on the part of the physician of industrial health problems. Thus far the average private practitioner has not shown a disposition better to understand nor is he greatly inclined to undertake more than the direct care of the patient's trauma. In short, he treats the injury but does not treat the worker. The private practitioner in handling occupational diseases encounters unusual difficulties. He not only encounters difficulties but he may make other difficulties both for his patient and for the employer.

The complaint has been made that medical schools do not furnish students with any adequate training with regard to occupational diseases. There is doubt that any medical school should undertake extensive training of this character as part of the undergraduate curriculum. The total number of disabling occupational diseases is far smaller than is widely believed. In Michigan during the past twelve months only 1,014 occupational disease cases were reported to the state department of health, but in this state there are 6,142 physicians. This means that every physician on the average will see only one case of an occupational disease about every six years. Since there are possibly 2,000 different substances in industry that may bring about occupational disease injury, it is remarkable that physicians do as well as they do. All students should be given fundamental training in occupational diseases. The second educational responsibility is the need for the training of much larger numbers of consultants in occupational disease work. It is remarkable that the internist is so little familiar with occupational diseases particularly with regard to causative factors and that even in large industrial communities there is such a dearth of qualified occupational disease consultants. This fact makes many good general practitioners loath to undertake occupational disease work because they feel that in so doing they must accept full responsibility. In every industrial community a fair number of practitioners consistently refuse this type of case for various reasons. These patients may seek the ministrations of a lower class of physicians.

A difficulty that the private practitioner creates for himself is too great acceptance of the patient's own statements as to the cause of his disease. Almost every worker hopes that any disease that may be his lot may be traced to work as the cause. On this account his history statements are prone to be colored with dubious assertions as to exposures to dusts, vapors, gases, mists and what not. The physician may be so little familiar with industry as to fall into error—may make himself ridiculous and may pave the way for controversies and lawsuits. Another difficulty that besets the physician is conflicting classifications. In some states hernia by law is classed as an accident, in others as an occupational disease. Carbon monoxide poisoning is widely accepted as an accidental injury but in some states is specified as an occupational disease. Many substances may produce an injury under one set of circumstances and an occupational disease under another. A further diagnostic difficulty may arise because so many industrially used substances are designated by trade names or code names that conceal their identity. A physician taking the history of a worker patient may seek to learn the substances handled in the course of employment. This worker may reply that he fills cans with "B-72". The physician may inquire as to the constituents of "B-72" and may be told by the workman that it is a mixture of "M-20" with "H-40" and "L-97". These may be the only names known in the entire department with reference to such chemicals. If the full facts were known, it would be somewhat as follows. This workman was engaged

in filling cans with a paint and varnish remover (B-72). This in turn represents a mixture of wood alcohol (M-20) with benzene (H-40) and a synthetic wax (L-97). All physicians may encounter difficulty in obtaining from the employer adequate information as to the chemical nature of the substances which the workman may have handled. This may not represent any unwillingness on the part of the employer to disclose this information, rather, the employer himself may not possess these facts. This situation is at the present time causing so much difficulty throughout the land that it may prove necessary to seek legislative action requiring adequate labeling of industrial materials of poisonous nature.

There is not available to the general practitioner any comprehensive but well condensed books suited to his needs. It is of course impossible that any thin book may be prepared that unflinchingly will furnish the general practitioner a full complement of occupational disease information, but the fact still remains that a useful purpose will be served by making available to all physicians a practical textbook on occupational diseases built around the needs of the patient.

While the total number of cases of occupational diseases per physician annually is low, the aggregate number is high both as to variety and as to numbers of patients. A larger number of cases of occupational diseases are never recognized or at least remain unreported. In every industrial state and many large industrial cities, public agencies should be maintained for the purpose of furnishing services to the practitioner, the employer, the patient and the labor unions, all on an unprejudiced basis, making available almost unlimited information on occupational diseases and industrial hygiene. The private practitioner should somewhat change his attitudes toward the services that he may render the industrial workman, losing sight to some extent of his immediate injury and instead render his services to the workmen as a whole, to his employer and to the community.

#### Means for Accomplishment

DR. GLENN S. EVERTS, Philadelphia. It has been demonstrated in Philadelphia since 1926 that small industries can have a medical service favorably comparable to that of larger industries and at a cost not out of proportion to that which larger industries have to pay. The Philadelphia Health Council developed a plan for making voluntary health examinations of the employees of small plants. It was hoped that this program would stimulate the industries to institute a permanent medical service. The response to this health examination program was sufficiently encouraging to warrant working out a plan for a medical service which would meet the needs of a plant having from twenty-five to 500 employees, and later an industrial secretary was engaged to explain its value to the executives of small industries.

The principal difference between offering a medical service to small plants and starting it in large ones lies in the matter of a part time schedule for the nurse and doctor as compared to a full time schedule. The original plan was to group two or more plants into a single unit for joint medical service. This was spoken of as an "industrial health unit." Each unit was to consist of almost 1,000 employees. One industrial nurse, if her time was carefully scheduled, could successfully serve that number of employees and do the necessary travel between plants. Half the time of an industrial physician likewise was found to be sufficient for that number of employees. During the demonstration period the industrial nurse was carried at full time on the staff of the health council, doing other types of health work until, as each plant was added, her time was entirely absorbed by industry. Likewise, during the demonstration period, the full time medical secretary of the health council, with previous experience primarily in industry, served as the industrial physician in starting the medical service in each plant.

In 1932 a modified plan was developed. An arrangement with the visiting nurse society was made to supply the necessary scheduled hours for each plant. This newer plan did away with the grouping of a few small plants into health units for the sake of making possible a part time schedule. A plant of any size under the arbitrary number of 500 employees

located in Philadelphia can begin a part time medical service whenever it elects to do so. Where the community enjoys the service of a visiting nurse society, the part time nurse's schedule would be simplified and the responsibility of the physician for details decreased. The original plan was put in operation by regular visits made throughout each week to each plant by the industrial physician and the full time nurse, each of whom gave a definite amount of service to each plant. The modified plan is simply that the private physician gives regular service to a single plant or perhaps to two plants with a different visiting nurse furnishing the nursing service for each plant. Each regular visiting nurse has a well trained substitute who is prepared to step in whenever necessary. The amount of service given was estimated that for every hundred employees the plant should receive three hours of medical service per week, one hour of this being physician's time and two hours nurse's time. There has been no reason to deviate from this allotment of time when trying to interest a plant in the service in the beginning, but experience has shown that this proportion of time per week to the plant population is minimal and that a hazardous industry, or an industry having a need for more health work, may require more service.

The service offered the small plant is the same now as it was in the beginning. It consists of the following items: (a) A typical examination taking an average of seventeen minutes on all present employees, preferably on a tactfully compulsory basis rather than on a voluntary one. (b) A physical examination on all new employees. (c) An annual reexamination of all employees, taking an average of fifteen minutes. (d) The assumption of the responsibility for the care of all plant accidents in the following way: (1) by taking care of the accident personally (physician or nurse) if the accident occurs during the hours of the medical service schedule, (2) by having a well chosen first aid person take charge in their absence and, when advisable, telephone the doctor, (3) arranging with the surgical service of the nearest hospital to take care of serious accidents, (4) assuming charge of redressing all accident cases either when the individual is still on the job or when off the job, if he is ambulatory and can travel back and forth to the plant dispensary, (5) arranging with an ophthalmologist to whom all plant eye accidents may be sent in absence of the physician or nurse. (e) The care of illnesses the individual may have while on the job, referring him to his family physician when he is too sick to work. (f) Attempting to diagnose chronic pathologic conditions and interpret their importance to the employee, referring him to his family doctor or diagnostic clinic. (g) Follow-up visits resulting from the original physical examination. (h) Home or hospital visits to the injured or sick in the capacity of a friend, never professionally, to determine the progress and estimate probable date of return to work for the benefit of the foremen of the department. (i) Health education—talks to groups of employees, posters on health bulletin boards, and pamphlets given to employees by the physician or nurse. (j) Sanitary survey of plant annually and frequent inspection throughout the year with particular reference to occupational hazards. (k) Accident prevention: (1) by cooperating with the safety program, (2) by getting an accurate report of the way each accident happened from the injured employee, (3) by following up the mechanical factor at fault to see that the accident does not happen again.

Experience has shown that in carrying out this program the nurse in the plant tends to become the key to the permanent success of the service even more than does the physician. She must assume not only the nursing duties but the administrative duties as well. This is especially true when she must work with a physician who has a private practice. The physician must rely on her for the first handling of many conditions which he will later review but which at the time may be considered an emergency. And yet without the sustained interest of the physician and his adherence to the hours scheduled much of the success of the program will fall by the wayside. In twelve years I have had yet to find any important executive in the plant who has attempted to influence me in matters involving medical or surgical judgment about an individual employee.

The present cost of a part time medical service is as follows: (a) Physician's time per scheduled hour, \$4. (b) Visiting nurse society's charge per scheduled hour, \$1.25. (c) Other items of cost based on a plant of 100 employees: (1) estimated cost per month of drug and dressing supply, \$15; (2) original cost of dispensary equipment—furniture, instruments, and so on, \$150; (3) original cost of drug and dressing supply, \$75; (4) original cost of constructing a two room dispensary including sink, electrical fixtures and outlets, from \$50 to \$500. If these items covering the original expense of setting up the complete dispensary are excluded, a plant of 100 employees could start a so called minimal service for about \$10 a week. Experience has proved, however, that the single one hour a week visit by the physician and the one hour a week visits by the nurse as a minimal service is inadequate even in the quite small plants.

Interesting an employer in medical service for his employees has been a matter of intensive education and salesmanship. Education by any other than direct interview was not fruitful. Repeated announcements of the availability of such a service were made through the chamber of commerce and the trade associations without a single inquiry being made as to further details. In spite of the fact that this representative was fully informed on industrial health work and skilled in the psychology of salesmanship, it often took several interviews with the most health-minded employer before he felt ready to institute the service. In securing the first nine or ten firms with a total of about 4,000 employees upward of 900 interviews and reinterviews were required. Of course, this included contacts with some forty or fifty firms which were not good prospects.

Six years has elapsed since the health council concluded its demonstration. During that time I have learned of no small plants in Philadelphia which have instituted any sort of a medical service, although probably a few have done so. It is my feeling that a much larger number of small plants would provide a medical service for its employees if the message were carried to the employer on purpose. Whether this should be done by the physician, the local medical society or some organization approved by the local medical society can be a matter for subsequent consideration.

The dispensary, ideally, should be located with reference to accessibility, light and freedom from noise, but in many small plants space is at so great a premium that there is little option as to location. The space when selected must be walled off to create a room, which is subdivided into a larger general treatment room and a smaller examining room as in the letter E. Experience has shown that it pays to draw the plans to scale and in sufficient detail to show the desired location of the dividing partition, the sink, the lights and the electrical outlets. Furthermore, the furniture and large pieces of dispensary equipment should be cut out of cardboard to scale and prearranged in their most effective dispensary location. The resulting layout will then be a precise guide to the workmen in building the dispensary, and a boon to the physician and nurse when beginning the service.

The original list of equipment and supplies has changed a little from time to time according to the efficiency of the newer items introduced to the profession. I have found, however, that the simplicity of the equipment remains essentially unchanged not so much because of the expense or even lack of room to house it as because of the lack of time to make the fullest use of it. I refer particularly to the finer equipment for diagnosis and physical therapy.

The service will get off to a better start if definite attention is paid to certain details of procedure at the time of opening the dispensary and in establishing a few important practices in the early weeks of its inception. The essential considerations are: (a) Talk to foremen and forewomen by physician, explaining purpose of dispensary and its relationship to all the employees. (b) On health bulletin boards, installed as a part of the work of equipping the dispensary, these notices: (1) first notice announcing the opening of the dispensary, (2) second notice to all employees "what to do in case of accidents", (3) third notice, especially to foremen, to notify the dispensary of absences of two days duration. (c) On health bulletin boards: (1) the dispensary schedule at all times, (2)

a monthly change of health posters and accident posters (d) From timekeeper (1) payroll by departments, including clock numbers, (2) names of absentees for any reason twice a week (e) An early trip through the plant by physician and nurse to become somewhat acquainted with the processes, location of departments, and accident and health hazards (f) Selecting and training first aid men or women (g) Location and contents of all first aid boxes (h) With superintendent (1) arrange for preemployment examination of all new employees, (2) arrange for the physical examination of the present employees in this order superintendent, forewomen foremen, and female and then male employees (i) Establishment of working relationship with claim agent of carrier of the plant's compensation insurance

The final step in this promotion of health work in small plants is the transfer of the service to the administration of the plants themselves. Since this work was in the nature of a demonstration on the part of the health council, it was not considered complete until it had been transferred. When, therefore, the work of the dispensary had been integrated into the routine of the plant and well established, it was turned over to the plant for future management. In the modified plan with the flexible hourly service of the visiting nurse society, only one or two plants needed to be considered and the transfer to the management became comparatively simple. With either plan a complete divorcing from the health council of the medical work of the plants was accomplished with no change in the character of the work and but little change in previous routine. The physician and nurse were placed on the payroll of each plant and were thereafter jointly responsible for the continued functioning of the dispensary at the same level of service as previously. The health council continued to manifest an active interest in the future welfare of each plant. Today, six years after the conclusion of its seven year demonstration, it maintains an interest in the progress of the medical services of the plants it was instrumental in starting.

The extent of the demonstration during those seven years can be gaged by these facts: (1) Dispensaries were established in thirty-one plants which represented a total number of employees of 9,721, (2) nineteen physicians and twenty-two nurses were employed for various periods in this work, and (3) the amount paid to those doctors and nurses was a total of \$62,078. The industries were diversified as to both kind and size. Of the thirty-one plants there were eleven confectioners, two cake and cookie bakers, two pork packers, one root beer manufacturer, three lithographers or printers, two woolen yarn or woolen knitting mills, one silk mill, one narrow tape mill, one blue serge suit manufacturer, one elastic goods mill, one iron and steel mill, one lead and alloy foundry, one cigaret factory, one paper bag maker, one paper box maker and one calf skin tannery. The number on the payroll in these plants varied from twenty-five in the yarn mill to 560 in the tannery, with an average of 200 for all plants. Many of the plants have discontinued the service. Of the thirty-one original plants, thirteen still maintain their medical service. Of the eighteen which discontinued the service the reasons, so far as have been learned, are as follows: nineteen apparently financial, four moved out of the city, leaving five the reasons for which are not known but which could be due to some fault of the service itself. I had the gratifying experience of spending from six months to two years in twenty-seven of these plants before they were transferred, and since 1932 I have continued personally to maintain the service in five of them as an increasingly interesting full time work.

I have fallen short of the goal we would all like to achieve. I have formed certain convictions from experience that a health salesman to carry the message personally to the employer is almost a necessity, that some means should be developed to help the average private practitioner learn more about the practice of medicine in industry and help him maintain permanent interest in his small plant work, and that when available the efficient, flexible nursing service of the visiting nurse society should be used. I feel that nothing but good can come from the local medical society, being prepared to point the way toward adequate medical service in small plants,

even though the idea of active promotion at first is not adopted. I suggest (1) that the Council on Industrial Health initiate the preparation of a pamphlet as a detailed guide for establishing a medical service in small plants, to be available to local medical societies, (2) that local medical societies establish a section of industrial health and (3) that a committee of the Council be formed to study the problem of presenting the medical service idea to small plants both by way of announcing its availability and by possible active promotion later on.

### Methods of Appraisal

DR LEVFRETT D BRISTOL, New York. In no field of medicine or public health have more rapid or significant developments recently taken place than in industrial health. The terminology and objectives of today are different from those of yesterday. A short time ago one spoke only of occupational diseases and accidents. Now one speaks of industrial health, including the prevention and control of syphilis as well as of silicosis, of tuberculosis as well as of traumatic neurosis, of pneumonia as well as of plumbism, of the common cold as well as of carbon monoxide poisoning, of heart disease as well as of heat exhaustion, and of off-duty accidents as well as of industrial injuries. The policeman approach to the problems of industrial hygiene is giving way to the medical and public health approach.

Industrial health implies not only that health should be promoted in industry but also that industry should take a leading part in community health. The vast majority of workers are employed by smaller plants and business concerns, most of which have little or no facilities for adequate programs of industrial health, largely because of the financial outlay involved.

A somewhat standardized survey and appraisal form would make it possible for the business executive of a smaller company to know what his company is doing or should be doing for employee health and what measurable progress is being made from year to year in the development toward an ideal program. What is most necessary is to give executives of smaller organizations at least an outline of what they ought to know about the essentials of an industrial health program. To help them evaluate a program of health services, an actual numerical rating scheme also might be valuable. It would not necessarily follow that each executive of a smaller plant or business would have to do all the things suggested or implied in a survey and appraisal form or that he would have to set up his own medical staff to carry on suggested activities. If he does not have the means in the way of adequately trained personnel to "carry on," the best thing for him to do is to find out where he can get it done. A fairly simple, standardized health survey form for smaller companies and business concerns could be used to survey health effort and performance in a very general way and would not attempt to stress the actual quantitative or qualitative services rendered. Such a form would visualize a fairly complete, well-rounded program, which is the first essential.

Since 1932 a Subcommittee on Industrial Health Appraisal of the Committee on Administrative Practice of the American Public Health Association has attempted, with partial success, to promote the health appraisal idea and plan in industry. Each year a growing interest in such a plan has been manifested on the part of various individuals, agencies and industrial organizations. Dejon and Simonds state with regard to the plan:

1 It has provided a list of definite health and accident activities which are essential to a constructive well rounded program of health service. This list of activities prepared and approved by medical authorities constitutes a scientific approach to the establishment of methods of procedure.

2 It has aided us in planning definite health activities for each ensuing year, guiding us in the direction of the ideal without undue experimentation. After the appraisal a definite program of health activities to be pursued for the current year is prepared and definite assignments of administrative responsibility for particular health activities are made to the various departments, units of organization or individuals which insure coordinated effort toward the completion of the program during the year. In this program management concentrates its energies on those particular health activities which are directly related to the immediate needs of its business.

3 It has provided through ratings a comprehensive measurement both to management and to health supervisors of the extent to which the various

planned health activities have been administered and it has also been a measurement of the progress we have made in approaching the ideal of an industrial health program. This method of measurement is far more stable and reliable than the old yardsticks such as the number of sickness days or the cost per case as compared with previous years, because many intangible factors affected such a measuring scheme. One year the influenza incidence may be high the next year low as a result of cyclic epidemics.

4 It has steadily strengthened interest in our health activities not only within the medical department and among the health counselors but also on the part of management at various organization levels.

While for various reasons the health survey and appraisal plan undoubtedly will make slow progress in larger industrial organizations, it may have its greatest usefulness as a stimulus and guide to smaller business concerns.

As an example of the possibilities involved in such an industrial health survey form, reference is made to a form recently adopted by the National Industrial Conference Board and distributed to about 800 industries in the board's present study of industrial health and medical services. Of the 800 industries now being studied by the board, about 450 are those having 500 or more employees and 350 having less than 500 workers. The survey form of the National Industrial Conference Board, through minor changes in arrangement and certain additions, is an improvement on our original health survey form for smaller industries. In contrast to forms used in the past by various agencies in their studies and reports on medical services in industry, this form in agreement with present trends in industrial health, specially emphasizes positive health promotion and general sickness prevention among workers.

Until such surveys, trial appraisals and reports have been compiled over a sufficient period of time, no final attempts can be made to develop an official, standardized appraisal form or method for promoting or measuring individual company performance in respect to industrial health services.

As specialists interested in the broad aspects of industrial health administration we must attempt to produce administrative tools for management and be prepared to interpret them to management in the language of management. No opportunity should be lost to emphasize the fact that industrial health surveys and appraisals are nothing more than important tools to help in planning, organizing and controlling business efficiency.

For smaller business concerns, much of the health service and medical work ultimately must be carried on either (a) by groups of these smaller concerns working together as units through some joint plan of centralization, as for example those in one building or trade group or in a restricted locality on the basis of divided costs for medical, nursing and other assistance required, or (b) by local community agencies, such as official health departments, tuberculosis and other voluntary or unofficial health agencies, university institutes of industrial hygiene, or organized local medical societies or groups of physicians.

#### DISCUSSION ON MEDICAL SERVICE TO SMALL INDUSTRIAL PLANTS

DR ELSTON L. BELKNAP, Milwaukee. The paper of Drs Heiser and Shafer presents an excellent statement of the scope of the problem as well as tangible evidence to show the small employer both the advisability and the feasibility of his inaugurating a real medical service. As chairman of the Committee on Occupational Disease of the Milwaukee County Medical Society, I have for the past four years been faced with the problem of arousing the interest in occupational hazards both in the small employer and of the physician who did his industrial work. In arriving at their annual cost of from \$10 to \$13.50 per man for medical care I wish to inquire as to just what they include under medical care. Is it just occupational illness and injury or does it include also actual treatment of nonoccupational disease or the ordinary disease of the community, which they state causes 90 per cent of absenteeism from industry? Certainly it would seem that Drs Heiser and Shafer do not include more than the diagnosis of nonoccupational disease in arriving at such a relatively low cost. As a part time consultant in occupational disease for eight years to a plant often falling just within the limit of 500 I have had the opportunity of studying men serially who have been exposed to dust of lead, copper, manganese and silica as well as to the volatile

solvents, cyanides and carbon monoxide. Not only the pre-employment but the frequent periodic examinations at two to four week intervals needed for certain of these workers not for treatment but for actual prevention of disability has made a medical cost of at least \$13.50 to \$15 per annum. This includes the cost of surgical treatment of injury. Should the cost of adequate annual protection of his worker run even to \$20, I do not believe the small American employer would be really appalled. Even that amount will still be good business and good humanitarianism. Dr McCord frankly faces the fact of present inadequacies both in the interest and in the specialized training of the private physician. I believe that both of these issues can and will be improved as we raise the level of general practitioner knowledge of industrial health by seminars and field trips sponsored by our medical society groups. Dr McCord has properly emphasized the need of specially trained occupational disease consultants in each community. These physicians should be able too to evaluate from their personal observation of plant processes and from engineering surveys the question of exposure to a toxic substance over against its effect on the human body. In this congress Dr Besley has reported that the worker receives the highest grade of preventive medical service when the same physician who treated him for occupational disease was also charged with the responsibility of inspecting his plant for hazardous conditions. I would add that such medical consultants should have the broad experience of general diagnosis gained in the field of internal medicine in private practice. Dr Everts has given a valuable account of one type of experiment in meeting the needs of medical service for the small industry in a large community. He demonstrates brilliantly the practicability of grouping two or more small plants into a unit for service by one physician and nurse. I approve the part time medical service which he suggests because I believe that the element of private practice provides a stimulus difficult to obtain otherwise. One might question the advisability of rigidly demanding a complete examination in from fifteen to seventeen minutes. A fixed price per hour of medical service—an hour packed with real service—is a good idea. I do not believe, however, that Dr Everts wishes us to take \$4 an hour as a standard for medical service. Varying circumstances of community custom as well as of personal skill and experience will call for corresponding levels of remuneration. Surely, such a key position as the physician holds for maintenance of proper employer-employee trust and human understanding should be adequately compensated. Physicians should no longer underestimate either their responsibilities or their value both to industry and to the worker. Dr Everts suggests the innovation of the local medical societies sponsoring the establishment of these "health units." I suggest another new departure. In certain instances why not allow the traumatic surgeon to attend the accidents of industry and the internist to help prevent the diseases of occupation. From my experience I have found such teamwork beneficial for employer, worker and physician. The appraisal form method of Dr Bristol should be of ever increasing value. We all benefit by such searching periodic self analysis. I have found that a monthly written review is of even more value than the time honored annual report. Dr Bristol stresses that we must learn to deal with business executives in their own language of analysis and inventory. We must never let them forget, moreover, that our prime responsibility is in the doctor patient relationship. To these ends may all interested parties continue to exchange experiences in repeated annual congresses on industrial health. Eventually we physicians of the American Medical Association may come together with a few generally admitted basic principles on effects of occupational disease on the worker and announce our agreement before the lay world on such questions as disability in uncomplicated silicosis or as to the likelihood and evaluation of percentage disability for residuals from specific industrial poisons.

DR A. G. KAMMER, Chicago. I should like to comment on a question or two raised in the paper by Dr Everts. There are certain reasons why an industrial medical examination has to be complete. 1 Men coming in for examination are not sick nor do they look sick. 2 They usually go to their family physician. 3 The purpose of the examination is to discover disease at its earliest stage. 4 Misdiagnosis destroys the confidence of men in the medical department. In the past three years I have made

7 000 examinations and have had an additional 6,000 made under my supervision. To do this work well it has been found necessary to take about twenty minutes per man. It takes enough time besides that to make records and to interview men and give them results of examinations, so that a doctor working very hard can't make more than eight examinations, and do them well, in less than half a day. My objection to the recommendation made by Dr. Everts is that I believe he is getting into our record here a standard which is too low for industry generally to accept.

DR. GLENN S. EVERTS, Philadelphia: Suppose we use the word "inspection" instead of "examination." I fully appreciate the fact that you can't examine a man in twenty minutes. Sometimes we take over a half hour for a thorough examination. But when the plant has had a strike, and they come back in one day and hire 100 new men, what are you going to do about it? You certainly aren't going to take half an hour for an examination. We call it an inspection and let it go at that.

### RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis, that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

March 1	Diabetes
March 8	Water Waste and Sanitation
March 15	Guarding Fresh Foods

<sup>1</sup> Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

### RADIO STATIONS BROADCASTING "YOUR HEALTH"

The following radio stations were reported by the National Broadcasting Company as taking the Your Health program Dec 31, 1938

WTAG	Worcester Mass	WIBM	Jackson Mich
WJZ	New York	WRDO	Augusta Maine

### THE ST LOUIS SESSION

#### Annual Tournament of the American Medical Golfing Association

The twenty-fifth annual tournament of the American Medical Golfing Association will be held at the Norwood Hills Country Club Monday May 15. Since there are from 250 to 300 contestants and many of the trophies are for thirty-six holes, which must be played on the Monday designated, the association is fortunate to have available two beautiful golf courses at this club. Following the tournament a dinner will be held at the club. There will be nine major events with nine trophies. There are also more than forty prizes to be awarded for various classes. These prizes include golf bags, golf clubs, traveling sets, golf jackets, cocktail sets, doctors' bags and other desirable articles. The president of the association is Dr. E. S. Edgerton, 106 North Main Street, Wichita Kan, and the executive secretary Bill Burns, 2020 Olds Tower, Lansing, Mich.

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

**Change in Status**—H. R. 3537 has been favorably reported to the House, proposing to extend the facilities of the United States Public Health Service to active officers of the Foreign Service of the United States.

**Bills Introduced**—S. 1218, introduced by Senator Sheppard, Texas, and H. R. 4035, introduced by Representative Beckworth, Texas, propose to amend the Social Security Act by adding a new title whereunder to aid the states to provide money payments to needy individuals who are 18 years or more of age and are permanently incapable of self support by reason of a physical disability or defect, not mental. S. 1416 introduced (by request) by Senator Ashurst, Arizona, proposes to make the provisions of the United States Employees Compensation Act applicable to all civil officers of the United States. S. 1428, introduced by Senator Andrews, Florida, proposes to grant service pensions to male contract nurses of the Spanish-American War. S. 1460, introduced by Senator Sheppard, Texas, contemplates that the retired personnel of the Army, Navy, Marine Corps, Coast Guard and Fleet Naval and Fleet Marine Corps reservists requiring hospitalization shall be entitled to enter any Army or Navy hospital on their own personal request, under the same conditions as are now or which hereafter may be, fixed for the active service. Applicants residing within an Army or Navy hospital area, who

require medical attention and who are unable, because of physical disability, to journey to such Army or Navy hospital, are to be accorded outpatient treatment on parity with active service personnel residing within the same hospital area. S. 1461, introduced by Senator Sheppard, Texas, proposes that hereafter the retired enlisted personnel of the Army, Navy, Marine Corps and Coast Guard, when hospitalized or domiciled in any Army or Navy hospital or United States Naval or United States Soldiers' Home, shall be extended such treatment or domiciliary care without cost. S. 1464, introduced by Senator Pittman, Nevada, proposes to extend the facilities of the United States Public Health Service to active officers of the Foreign Service of the United States. H. R. 3602, introduced by Representative Youngdahl, Minnesota, proposes to authorize an appropriation of \$650,000 to construct a United States Veterans Administration domiciliary unit to provide 700 beds at Fort Snelling, Minnesota. H. R. 4091, introduced by Representative Risk, Rhode Island, proposes to authorize an appropriation of \$1,000,000 to construct a veterans' neuropsychiatric hospital and domiciliary facility in Rhode Island with a capacity of at least 400 beds. H. R. 4170, introduced by Representative Mundt, South Dakota, proposes to enact a Navigable Waters Antipollution Act. H. R. 4188 introduced by Representative McCormack, Massachusetts, proposes to authorize an appropriation of \$2,000,000 to construct a veterans' hospital in or near Boston with a capacity of 300 beds.

## STATE MEDICAL LEGISLATION

## Alabama

*Bill Introduced*—H 161 proposes to require each applicant for a marriage license to present a certificate from a licensed physician that the applicant has been examined for venereal disease and, in the opinion of the physician, is either not infected with venereal disease or, if infected with syphilis, is not in a stage of that disease which is communicable. The examination by the physician is to include a physical examination, an approved laboratory test for syphilis and, when indicated, a microscopic test for gonorrhea.

## Arkansas

*Bills Introduced*—H 423 proposes to enact a workmen's compensation law (1) to require employers to pay stated compensation to workmen suffering "accidental injury or death arising out of and in the course of employment, and such occupational disease or occupational infection as arises naturally out of such employment or as naturally or unavoidably results from such accidental injury" and (2) to provide to injured workmen "such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches, and apparatus as may be necessary during sixty days after the injury or for such time in excess thereof as in the judgment of the [Workmen's Compensation] Commission may be required." Apparently the injured workman is to be entitled to select his own physician only in an emergency or if an employer fails or neglects to provide one. H 434 proposes that all actions for malpractice against physicians, dentists and hospitals must be commenced within three years after the accrual of the cause of action. The bill also proposes that a cause of action shall not be deemed to have accrued until the date it is discovered by the patient. S 219, to amend the law providing that no licensed physician shall be compelled to disclose in a civil action any information which he acquired from his patient while attending in a professional capacity, proposes to give a similar privilege to trained nurses.

## California

*Bills Introduced*—S 548 proposes so to amend the Insurance Code as to permit the organization of corporations to operate so called nonprofit health and hospital service plans whereby there may be furnished by those corporations to their subscribers (1) medical care through licensed physicians employed by the corporation, (2) hospitalization, (3) nursing care, (4) dental care (5) and drugs and medicines. S 696 proposes to authorize county boards of education to require school teachers to present certificates from physicians that they have submitted to physical examinations within three years last past and have been found free from tuberculosis. A 1018, to amend the State Food and Drug Act, proposes, among other things (1) to redefine the term "drug" so as to include specifically "all chemicals or substances of whatsoever nature in the treatment of obesity due to whatever cause" and (2) to provide that the standard of purity of drugs shall be that of the United States Pharmacopeia and National Formulary and such further standards of strength, quality or purity as the state board of health may make relating to drugs not in the United States Pharmacopeia or in the National Formulary, and the regulations and definitions adopted for the enforcement of the federal Food and Drugs Act of 1906. A 1019 proposes to make the sale dispensing administering or prescribing of diphenylamine for any purpose a felony. A 1131, A 1147 and A 1177 propose to enact a new law to regulate the sale and distribution of drugs, cosmetics and therapeutic devices. A 1147 and A 1177 propose to regulate also the sale and distribution of food. A 1515, to amend the workmen's compensation act, proposes (1) to give an injured employee the right to select a consulting physician, at the expense of the employer, if the employee is dissatisfied with the medical treatment being received from the physicians retained by the employer or insurance carrier, and (2) to provide that no injured workman shall be required to submit to an examination by an independent expert medical examiner selected by the industrial commission. S 517 S 1208 and S 1215 propose to enact a so called "Consumers Protection Act to regulate the sale distribution and advertising of food, drugs, cosmetics and health devices

S 524 proposes to authorize the director of institutions, with the approval of the State Board of Control, to provide an institutional unit or units for the custodial care and treatment of defective or psychopathic delinquents of both sexes. S 551 proposes to enact a compulsory health insurance act whose so called benefits are to be available to all employees in the state and to such other persons as voluntarily elect to come under the act. The benefits are to consist of all forms of medical, dental, hospital and nursing services, cash payments in the event of disability, and certain cash maternity benefits. These benefits are to be paid for from a payroll tax amounting to 6 per cent of wages paid. S 1128 and A 2172 propose to establish a system of compulsory health insurance applicable to all persons now subject to unemployment insurance. The bill proposes to make available to such individual all forms of medical, dental and hospital services which will be paid for by means of an additional payroll tax. The bill also proposes to permit any other person to elect to come under the act if his annual income is not more than \$3,000. A 1203 proposes to enact an independent naturopathic practice act and to create a so-called "self-sustaining board of naturopathic examiners" to examine and license persons desiring to practice naturopathy. A 1505, to amend the Business and Professions Code, proposes that "All advertising of medical business or the actual practicing of any system or mode of treating the sick or afflicted, which is intended or has a tendency to deceive the public or impose upon credulous or ignorant persons and so be harmful or injurious to public morals or safety constitutes unprofessional conduct within the meaning of this chapter." A 1574 proposes to make it a felony for any person to sell, dispense, administer or prescribe dinitrophenol for any purpose. S 817 proposes to restrict the retail sale and distribution of "any registered, trade-marked or copyrighted preparation or compound registered in the United States patent office" containing barbitol to sale or distribution on the prescription of a licensed physician, dentist or veterinarian. The present law imposes such a restriction on the sale of such a registered, trade-marked, copyrighted preparation only when it contains more than forty grains to the avoirdupois or fluid ounce. S 990 proposes to create the dental corporation of California, which is to consist of all licensed dentists and licensed dental hygienists in the state. The corporation is to be governed by a State Dental Board, whose members are to be selected eventually by members of the corporation. The present members of the Board of State Dental Examiners are to constitute the first State Dental Board, but as their terms expire they are to be replaced by persons selected by the corporation. The State Dental Board is to exercise all the rights and assume all the duties now in the Board of Dental Examiners. The bill also proposes to repeal the existing laws relating to the practice of dentistry and to enact an entirely new dental practice act. This bill, so far as it will integrate the dental profession is quite similar in theory and set up to so called bar integration acts in force now in a number of states. S 1183 proposes to regulate the use of x-rays and x-ray appliances in connection with the examination of the jaws, teeth, alveolar process, gums, and the immediate adjacent structures of living human beings, as an aid to the diagnosis and treatment of diseases and lesions pertaining thereto. The bill proposes to create a dental x-ray qualifying committee to determine the qualification of applicants for permits authorized by the bill and to report the qualifications to the Board of Dental Examiners, which on the recommendation of the committee will issue such permits to qualified applicants. Two permits are proposed by the bill: first an unlimited permit, the holder of which is to be called a dental roentgenologist and is to be authorized to diagnose and treat the diseases and lesions of the jaws, teeth, alveolar process, gums and immediate adjacent tissues by means of x-rays or radiographs and to own, possess, or operate x-ray devices or x-ray laboratories, second a limited permit the holder of which is to be called a dental radiographer and is to be authorized to own, possess or operate a dental x-ray laboratory and to render technical descriptions of the shadows visible in roentgenograms to those licensed by law to diagnose ailments and treat the sick. The bill specifically provides that it is not to be construed to prohibit the ownership, possession or operation of x-ray devices

used for the lawful diagnosis and lawful treatment of persons by licensed physicians, dentists, osteopaths, drugless practitioners or chiropractors A 1307 proposes stated state and county aid to persons convalescing from tuberculosis A person is to be deemed convalescing until he is able to return to the regular employment in which he was engaged prior to contracting tuberculosis A 1712, to amend the law authorizing the organization of corporations to operate nonprofit hospital service plans, proposes in effect to permit such corporations to enter into contracts covering the "indemnification of the beneficiary or subscriber for the costs and expense of professional medical service rendered in connection with hospitalization" A 1796 proposes to prohibit the manufacture, advertising, sale or transportation of adulterated, mislabeled or misbranded cosmetics and to regulate the traffic in cosmetics and complexion soaps A 1874 proposes a system under the supervision of the State Department of Public Health, for providing medical care, including medical, dental, nursing and hospital care and the supplying of pharmaceutical and therapeutic appliances to needy persons, the cost of which is to be apportioned between the state and the counties The bill specifically provides that, subject to the rules and regulations adopted by the department, "medical care shall be provided to any resident of the State who has not sufficient income

to provide himself and his dependents with proper medical, dental, nursing, hospital, pharmaceutical, and therapeutic appliance care, without depriving himself or his dependents of necessary food, clothing, shelter, and similar necessities of life" S 657 proposes to establish a health and safety code, which contains provisions relating to, among other things, (1) the duties and rights of the State Department of Health and local health departments and officers, (2) the regulation of clinics and dispensaries and maternity hospitals, (3) the quarantine laws of the state, (4) the maintenance of tuberculosis hospitals by governmental subdivisions, (5) sanitation and sanitary districts, (6) dead bodies, their burial, removal and disinterment, including the disposal of unclaimed dead bodies, (7) cemeteries, (8) vital statistics, and (9) the regulation of the possession and distribution of narcotic drugs

#### Connecticut

*Bills Introduced*—S 168 proposes to enact a separate practice act for practitioners of physical therapy, physical culture and massage, and to create a board of examiners to examine and license persons desiring to practice in the fields indicated Apparently the maximum educational qualification to be required of applicants for such a license is graduation from a college or school giving a course in physical therapy, physical culture or massage after pursuing courses for at least two years of eight months each S 320 proposes to authorize the judges of the superior courts to appoint in each congressional district a medical consultant to the compensation commission to investigate and determine, when directed by the compensation commissioner, the pertinent facts pertaining to the physical and/or mental status and condition of claimants for workmen's compensation H 294 proposes to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis Every other person permitted by law to attend pregnant women but not permitted to take blood tests must cause a sample of blood to be taken by a duly licensed physician and submitted to an approved laboratory H 857 proposes to authorize the state medical society and the county medical societies in Fairfield, Hartford, Litchfield, Middlesex, New Haven, New London, Holland and Windham counties, jointly or severally, to incorporate for the purpose of operating a medical service corporation The bill proposes to define a medical service corporation as "a non profit sharing Corporation without capital stock organized under the laws of the State for the purpose of establishing, maintaining, and operating a plan, whereby medical service may be provided, at the expense of said corporation by members of the medical association or associations to subscribers under contract entitling such subscriber to certain medical services" S 538 proposes to authorize the trustees of the Connecticut State Hospital to establish a school for the training of psychiatric attendants S 875 proposes to require

the State Commissioner of Welfare to provide for the medical care of recipients of old age assistance S 921 proposes to authorize the judges of the superior court to appoint for each county a coroner and a deputy coroner who must be attorneys at law S 931, to amend the osteopathic practice act, proposes that any person who is a graduate of a college of osteopathy the curriculum of which has the written approval of the National Society of Osteopathy of the United States on passing an examination on the subjects taught in the college and prescribed by the Board of Osteopathic Registration and Examination is to be entitled to practice in all subjects contained in the examination H 1495 proposes to require the governor to appoint a commission of five to study and investigate the subject of health insurance S 780 proposes to prohibit the sale of any arch support, braces or other foot or leg appliances except on the prescription of an orthopedic surgeon or of the state health commissioner H 1013, to amend the naturopathic practice act, proposes to permit naturopathic licentiates to prescribe or administer dehydrated foods and concentrations properly labeled as such, tissue salts normally found in the human body and non poisonous herbs H 593, to amend the law prohibiting the employment in a bakeshop of any person "affected with pulmonary tuberculosis or a scrofulous or venereal disease or with a communicable skin affection," proposes to impose a similar restriction on the employment of persons with diphtheria, dysentery, paratyphoid fever, poliomyelitis, scarlet fever, smallpox, streptococcus sore throat or typhoid fever except on the written authorization of the health officer

#### Delaware

*Bills Introduced*—H 46 proposes to establish, under the direction and control of the State Board for Vocational Education, a division for the vocational rehabilitation and placement in remunerative employment of persons whose capacity to earn a living is or has been destroyed or impaired S 26, to amend the medical practice act, proposes, among other things, to authorize the refusal or the suspension or revocation of a license to practice medicine, in addition to the causes now stated in the law, for "chronic drug addiction" or for "violation of rules and regulations adopted [by the Medical Council] for the supervision and control of professional conduct"

*Bill Passed*—H 54, to amend the provisions of the medical practice act relating to osteopathy, was introduced February 6 and passed the house February 9 The bill proposes that osteopathic applicants (1) be examined by the medical council and an osteopath designated by the Delaware State Osteopathic Society, (2) be examined in the subjects now enumerated in the law and, in addition, in "Therapeutics", (3) must present evidence, in addition to the evidence of qualifications now required by law, that they have completed two years of acceptable college work, including English, physics, chemistry and biology, and have served as interns for one year in hospitals recognized by the American Osteopathic Association or by the American Medical Association

#### Illinois

*Bills Introduced*—S 52 proposes to grant to hospitals, physicians and dentists treating persons injured through the negligence of others liens on all claims, rights of action, judgments and compromises accruing to the injured persons because of their injuries H 110 proposes to prohibit the operation of a private hospital, nursing home, resting home or sanatorium unless licensed by the Department of Registration and Education and to impose an annual license fee of \$25 on hospitals so licensed

#### Indiana

*Bills Introduced*—H 114 proposes to require every physician within twenty-four hours after first learning of the existence of an occupational disease to report the facts to the State Board of Health H 225 proposes to increase to 180 days from ninety days the period after an industrial injury during which an employer must furnish, free of charge, to an injured workman necessary medical and hospital services H 276 proposes to enact a separate drugless practitioner's practice act and to create a State Board of Drugless Examiners for drugless practitioners to examine and license applicants for such licenses A license

issued by this board is to designate the school or college of healing to which the practitioner belongs and is to entitle the holder to practice said designated branch of drugless healing and to use natural, physical, manipulative, nutritional, electrical, mechanical and other drugless measures in the treatment of disease but is not to authorize the licentiate to practice operative surgery or obstetrics or to administer or prescribe any drug. The bill proposes to prohibit any licentiate from using the term "doctor" or "physician" unless he indicates that he does not use drugs or surgery in the treatment of disease.

#### Iowa

*Bill Introduced*—H 307 proposes to authorize the organization of nonprofit corporations to contract to furnish hospital service to subscribers and to contract with hospitals to furnish the hospital service to its subscribers when needed. At least a majority of the directors of such corporations must be at all times administrators, or directors, trustees or members of the clinical staff of hospitals which have contracted or may contract with such corporations to render to their subscribers hospital service.

#### Kansas

*Bill Introduced*—H 259, to amend the chiropractic practice act, proposes to require chiropractors to renew their licenses annually and to condition that renewal on the furnishing of satisfactory evidence to the board of chiropractic examiners that they have attended at least two days of the annual educational program as conducted by the Kansas chiropractors association or a postgraduate course equivalent thereto in the year preceding application for renewal.

#### Maine

*Bill Introduced*—H 1195 proposes, as a condition precedent to the issuance of a license to marry, that both parties to the proposed marriage present physicians' certificates that they have been given a standard test, as required by the State Department of Health and Welfare for the discovery of syphilis and gonorrhea, made on a day not more than twenty days prior to the date of application and that, in the opinion of the physicians, neither party is infected with syphilis or gonorrhea or, if so infected, is in a stage whereby the disease may become communicable.

#### Maryland

*Bills Introduced*—H 103 proposes to require a physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis. Every other person permitted by law to attend pregnant women but not permitted by law to take blood tests is to cause a sample of the blood of such pregnant woman to be taken by a duly licensed physician and submitted to an approved laboratory. S 85 proposes to enact a separate naturopathic practice act and to create a board of naturopathic examiners to examine and license persons to practice naturopathy.

#### Michigan

*Bills Introduced*—S 93 proposes that, whenever any person charged with an offense punishable by life imprisonment has been bound over to the appropriate court, the clerk of that court is to notify the State Hospital Commission which is to cause the person to be examined by psychiatrists to determine the existence of any mental disease or defect which would affect his criminal responsibility. H 140 proposes to require a physician making a diagnosis of pregnancy to make both a clinical and a laboratory test of the patient for venereal disease and if the test shows a venereal disease, to institute proper treatment. The cost of all tests and treatments, if the patient is unable to pay for them, is to be paid from the appropriation to the Michigan Department of Health. H 145 proposes to authorize the organization of corporations to operate nonprofit hospital service plans whereby hospital service may be provided by any hospital or group of hospitals with which such corporations have contracts to such of the public as become subscribers to the plans entitling each subscriber to stated hospital care.

#### Missouri

*Bill Introduced*—H 182 proposes to prohibit the sale, prescription or fitting of any hearing aid device except on the written prescription of a licensed physician.

#### Montana

*Bills Introduced*—S 51, to amend the chiropody practice act, proposes, among other things, (1) that "Chiropody (sometimes called Podiatry) shall mean the diagnosis, medical, surgical, mechanical, manipulative and electrical treatment of ailments of the human foot", and (2) to provide that the State Board of Chiropody Medical Examiners consist of the secretary of the State Board of Medical Examiners, one physician selected by the Board of Medical Examiners from its membership, and three chiropodists appointed by the governor from a list of names submitted by the Montana Association of Chiropodists. H 180, to supplement the workmen's compensation act, proposes to provide compensation and medical and hospital care for silicosis contracted by a worker in any occupation wherein there is an exposure to silica dust. The bill proposes to define silicosis as "a fibrotic condition of the lungs caused by inhalation of silica dust sufficient to render the workman incapable of following his regular occupation." S 28 proposes to require local and county health officers to make complete physical examinations of public school children within sixty days after their first enrolment in school. If it is found that a child is suffering from a contagious or infectious disease, the health officer must exclude the child from school and such child may not be readmitted until the officer certifies that the contagious or infectious condition has been removed. S 83 proposes to make the possession, sale or distribution of peyote (pellote) or anhalonium unlawful. The bill specifically provides however that it shall not apply to "transporting, possessing or using said peyote for religious sacramental purposes within the boundaries of an Indian reservation." H 177 proposes to create the office of medical referee for each county in the state. The medical referee is to be a licensed physician, whose duties are to determine, with the advice of the county attorney, as to whether it is necessary for the county coroner to hold an inquest on the remains of any deceased person. Apparently, only on the finding of the medical referee as to the necessity of an inquest may a county coroner proceed with an inquest. H 101 proposes to enact a food, drug and cosmetic act and to regulate the manufacture, sale, distribution and advertising of foods, drugs, cosmetics and devices.

#### Nebraska

*Bills Introduced*—Bill 181, to amend the provisions of law setting forth the educational qualifications required of applicants for licenses to practice osteopathy, proposes, in addition to existing educational qualifications, that an applicant beginning the study of osteopathy after Dec 31, 1940, must present proof of having completed, prior to his study of osteopathy, two years' study in a college or university. Bill 444, to amend the laws relating to the practice of chiropractic, proposes among other things (1) to define chiropractic as "the science of locating and removing interference with the transmission of nerve energy" and (2) to permit licentiates to practice chiropractic as taught in an accredited school or college of chiropractic [and] to use light, heat, air, water, food, and exercise, as factors of health, and of chiropractic in the treatment of disease and the right to use electrotherapy to facilitate chiro adjustment."

#### Nevada

*Bill Passed*—A 41 passed the assembly February 6, proposing to repeal the law approved March 22, 1921, entitled "An act to prohibit advertisements or manufacture and sale of cures or medicine relating to venereal disease and certain sexual disorders."

#### New Jersey

*Bills Introduced*—A 48 proposes to require the medical inspector in every school district in the state to make eye and ear tests of public school pupils at least once annually. The bill also proposes to authorize the board of education of each school district to appoint specialists for eyes and ears and to fix their compensation, the specialists to assist the medical

inspector in making the tests required by the bill S 15, to amend the pharmacy practice act, proposes to permit persons other than licensed pharmacists to sell commonly used household and domestic remedies in original unopened packages

### New Mexico

*Bills Introduced*—S 30 proposes to authorize the Department of Public Welfare to enter into a contract with the Holy Cross Sanitarium at Deming to treat state and other governmental employees for the ailments noted. No charge is to be imposed on such employees as are afflicted with tuberculosis, cancer, asthma, bronchitis, rheumatism and skin diseases other than a 25 cent month deduction, which the bill authorizes to be deducted from their salaries. The bill also proposes to authorize the department to obtain an option to purchase Holy Cross Sanitarium within two years at not to exceed \$250,000. S 68 proposes to enact a so-called uniform food, drug and cosmetic act to regulate the sale, distribution and advertising of foods, drugs, cosmetics and therapeutic devices. S 47 proposes to make it unlawful for any child to attend school, or for any teacher to allow a child to attend school, unless the child is immunized against diphtheria. H 102 proposes to direct the Department of Public Health to preserve by proper scientific means such eyes of stillborn infants as it may receive and to distribute them in cases of blindness caused by corneal lesions when in the judgment of an eye specialist attending a particular patient their use would be indicated. The bill proposes to make it the duty of every practicing physician on delivering a still-born child to report, with the consent of the mother, the facts to the department so that no delay may be had in procuring the eyes and preserving them. No such eyes are to be received or accepted except with the full consent of the mother, and its father, if the father is living with the mother, and the department when such consent in writing is obtained may make such examination of the parents and of the child as would determine the feasibility of using such eyes for the purposes indicated above. S 112 proposes to authorize the organization of corporations to operate nonprofit hospital service plans whereby hospital care may be provided by the corporations or by hospitals with whom they have contracted to such of the public as become subscribers to the hospital service plans operated by such corporations. H 123 proposes that, when a person convicted of a crime is found by a jury either to be a habitual drunkard or to have been under the influence of liquor at the time of the commission of the crime of which he is convicted, the trial court, after imposing sentence, may suspend sentence on condition that the defendant take treatment under the supervision of the department of public welfare and that after taking such treatment he does not become intoxicated for five years. The cost of the treatment must be borne by the defendant, if he is financially able to do so, otherwise the necessary expenses will be paid by the state. The bill also provides a procedure whereby any alcoholic who is unable to pay for treatment may be treated at the expense of the state.

### New York

*Bill Introduced*—S 572, to amend the law prohibiting the operation of a motor vehicle without a license to do so, proposes to make it a condition precedent to the issue of such a license that the applicant present a certificate of a licensed physician that the applicant has been examined by him and found to have no physical defect which, in his opinion, would render the applicant unfit to drive a motor vehicle.

### North Carolina

*Bills Introduced*—S 88 proposes to provide a uniform procedure for the suspension or revocation by various North Carolina boards and commissions of licenses to engage in trades, professions and lawful callings. H 258 proposes to forbid the sale of all medicinal preparations, whether proprietary, patented or sold on the prescription of a licensed physician, containing acetanilid or any of the bromides, unless the containers are marked "poison." S 121 proposes, as a condition precedent to the issuance of a license to marry, that each party to the proposed marriage present a physician's certificate executed within seven days from the date of application that by the usual

methods of examination the physician has found no evidence of any venereal disease in the infectious or communicable stage or of tuberculosis. Such certificates must also state that the applicant is not an idiot, an imbecile, a mental defective, of unsound mind or subject to epileptic attacks. S 120 proposes that every woman who becomes pregnant shall have a blood sample taken and submitted to a laboratory approved by the State Board of Health for performing an approved test for syphilis and that any licensed physician shall, on the request of the woman, secure or cause to be secured a sample of her blood and submit it to an approved laboratory for the performance of the test indicated.

### North Dakota

*Bills Introduced*—S 197, to amend the medical practice act, proposes to increase the penalty for practicing medicine without a license or for violating any provision of the medical practice act, by authorizing the imposition of a fine of from \$50 to \$500 and/or imprisonment in the county jail not exceeding one year, or both. Under the present law the fine authorized is from \$50 to \$300 and/or imprisonment from ten to thirty days. The bill also provides that any person convicted for the second time for violating any of the provisions of the medical practice act is to be deemed guilty of a felony. H 287 proposes to enact a separate naturopathic practice act and to create a board of naturopathic examiners to examine and license persons applying for such a license. S 155 and H 350 proposes to repeal existing laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act.

### Ohio

*Bills Introduced*—H 171 proposes to create a "public health study commission" to study all laws and acts concerning public health, organization of group medical service, compulsory health insurance, cooperation between groups and associations and agencies for the furnishing of medical and hospitalization services, and all other factors concerning and affecting the social problem of the availability of medical care and facilities to the people of the state. This commission is to make a full report of its findings and recommendations to the governor on or before July 1, 1939. H 52 proposes to create a commission to study and investigate the possibilities for the rehabilitation of the visual and the physically handicapped of the state. S 97, to amend the medical practice act, proposes (1) to require an applicant for a license to practice to have a minimum preprofessional education of two years of collegiate work in an approved college of arts and sciences, (2) to permit the State Medical Board to refuse to examine applicants licensed to practice in a foreign country if that country does not extend a like privilege to Ohio licentiates, (3) to require applicants for licenses by reciprocity to possess the minimum educational qualifications required of applicants for licenses after examination, and (4) to provide that fines collected for violations of the medical practice act are to be distributed one half to the board and one half to the county or municipality in which the offenses were committed. S 104 proposes to authorize the organization of corporations not for profit to establish and operate group medical service plans under which such corporations, as intermediaries effect contracts between persons duly licensed to practice medicine and persons, firms or corporations for the furnishing of medical or surgical care, to subscribers for stipulated instalment payments.

### Oregon

*Bills Introduced*—S 311, to amend the workmen's compensation act, proposes, in effect, to permit an injured workman to have his injuries treated at state expense by any person licensed to practice any of the healing arts. H 313, to amend the laws conferring stated powers on the State Board of Health with respect to communicable diseases, proposes that the term "communicable diseases" as used in the act shall include tuberculosis in a communicable stage.

### Pennsylvania

*Bill Introduced*—H 204 proposes to authorize the sexual sterilization of inmates of state institutions who are idiots imbeciles or feebleminded.

## South Dakota

*Bills Introduced*—H 78 proposes to raise the maximum liability of an employer for medical and hospital services rendered an injured workman to \$400 and to extend to twenty weeks the period after an industrial accident during which the employer must provide such services. H 133 proposes to permit any registered pharmacist conducting a pharmacy and having in stock drugs of a value of not less than \$2,000 to sell, on the prescription of a licensed physician, whisky and brandy of the kind and character recognized and defined by the United States Pharmacopeia for medicinal purposes. To avail himself of this right, however, a pharmacist must receive from the Secretary of Agriculture a permit to do so and to pay a fee of \$10 annually. H 92 proposes to enact a so-called "basic science act" which is a basic science act in no reasonable sense of the term. The bill proposes to prohibit the State Medical Examining Board, the Chiropractic Examining Board and the Osteopathic Examining Board from admitting to examination any applicant who has not passed a satisfactory examination in anatomy, physiology, bacteriology, pathology and chemistry. However, instead of such applicants being examined by an impartial board in the subjects enumerated, examinations in those subjects are to be given by the medical, chiropractic or osteopathic boards themselves "to applicants for license in their respective professions."

## Tennessee

*Bill Passed*—H 354 passed the House February 2, proposing extensive amendments to the chiropractic practice act. Among other things it proposes (1) to make eligible for examination for licensure any applicant who is of good moral character, who has a preliminary school education equal to that of a standard accredited high school, and who is a graduate of a school of chiropractic giving adequate courses of anatomy, physiology, symptomatology, spinal analysis, hygiene, sanitation, principles and practice of chiropractic, and requiring actual attendance of three school years of not less than nine months each, or 3600 hours of actual class attendance, (2) to raise the examination fee to \$25 from \$15, (3) to raise to \$50 the fee for issuing a license without examination, and (4) to set out causes for the revocation, suspension or refusal of licenses. A companion bill (S 255) is now pending in the senate.

*Bills Introduced*—H 504, to amend the workmen's compensation act, proposes to increase the liability of an employer for medical aid rendered an injured workman to \$300 from \$100 and for hospital care to \$300 from \$100. S 411 proposes extensive amendments to the existing osteopathic practice act which without doubt will grant to osteopaths now licensed and to be licensed in the future the right to practice medicine and surgery without restriction. Specifically the bill states that a license to practice osteopathy shall entitle the holder thereof "to practice osteopathy in any county in this State, in all its branches, as taught and practiced by the recognized associated colleges of osteopathy, with the right to use such drugs as are necessary in the practice of osteopathy, surgery, and obstetrics, including narcotics, antiseptics, anesthetics, and biologicals. Osteopathic physicians and surgeons licensed hereunder shall have the same general rights as physicians or surgeons of other schools of medicine including the right to register under the Federal Narcotic Act." The bill proposes that after 1944 all applicants for licenses must have "completed two years of college education, of college grade, in a recognized college or university, prior to enrolling in an osteopathic college." As indicative of the scope of osteopathy, applicants are to be subjected to examination in anatomy, chemistry, physiology, pathology, bacteriology, *preventive medicine*, diagnosis, toxicology, *pharmacology*, *therapeutics*, *surgery*, gynecology, obstetrics, *medical jurisprudence*, practice of osteopathic medicine, and such other subjects as the board may require. The bill proposes to permit the board to license without examination applicants (1) duly authorized to practice osteopathy in any other state or (2) holding certificates issued by the National Board of Examiners for Osteopathic Physicians and Surgeons. H 664 and S 499 propose to enact a law to prohibit the manufacture, distribution or advertising of adulterated foods, drugs, cosmetics and devices.

## Texas

*Bills Introduced*—H 246 proposes to designate tuberculosis as a communicable disease and to require every physician to notify in writing the appropriate health officer of every case of any form of tuberculosis which comes under his professional observation. The bill proposes to require the appropriate health officer when he learns that any person afflicted with tuberculosis fails to conduct himself in such a manner as not to expose others to danger of infection to petition the probate court to commit the infected individual to any approved institution established for the care of persons suffering from tuberculosis. H 465, to amend the workmen's compensation act, proposes in effect to permit an injured workman to select, at the expense of the employers' insurance association, a physician of his own choice to treat his industrial injuries. S 101 proposes to appropriate \$150,000 to the State Department of Health to assist in the eradication of venereal diseases in the state.

## Washington

*Bills Introduced*—S 322 proposes to create a "Washington State Chiropractors' Association," which is to operate as an agency of the state and is to be composed of all persons licensed to practice chiropractic in the state. The association apparently is to have the power to fix the qualifications requirements and procedure for admission to the practice of chiropractic and to establish and enforce rules of professional conduct for its members. H 261 proposes to repeal the present laws relating to the possession, distribution and sale of narcotic drugs and to enact what appears to be the uniform narcotic drug act. H 280 proposes that "No person, firm, association or corporation shall either directly or indirectly solicit contract, collect, receive or transmit compensation for services in the exercise of any of the healing arts, nor conspire, agree or attempt to do any of said acts, except for and on behalf of a principal or principals all of whom are duly licensed under the laws of this state to perform such services." H 302 proposes in effect to permit any licensed practitioner of the healing art to render the medical aid called for by the workmen's compensation act.

## West Virginia

*Bill Introduced*—S 21 proposes to enact a so-called uniform food, drug and cosmetic act to prohibit the manufacture, distribution or advertising of adulterated or misbranded drugs, foods, cosmetics and devices.

## Wisconsin

*Bill Introduced*—A 227 to amend the basic science act, proposes in effect that chiropractic applicants submitting to the basic science examination shall be examined by chiropractors designated by the State Board of Examiners of Chiropractic.

## Wyoming

*Bills Introduced*—H 54 proposes to authorize the State Board of Charities and Reform to establish in or near the State Park at Thermopolis an orthopedic hospital for the prevention, treatment and care of infantile paralysis and other like diseases. H 106, to amend the optometry practice act, proposes, among other things, to define optometry as "the employment of any means other than the use of drugs for the measurement of the powers or range of human vision or the determination of the accommodative and refractive status of the human eye or the scope of its functions in general or the adaptation of lenses or frames for the aid thereof." H 125, to amend the chiropody practice act, proposes (1) to amend the definition of minor surgery on the feet, which chiropodists are permitted to perform, so that the term shall mean the surgical treatments of the ailments of the human foot and leg, except amputation of the foot or leg or the use of anesthetics other than local. (2) to require applicants in addition to the educational qualifications now required to have had two years in a recognized college of liberal arts and sciences. (3) to provide that "Any person who shall use objectionable display, advertising in any manner being detrimental to the dignity of the profession, and therefore unprofessional shall be punished by the provisions of this Act" and (4) apparently to make the term "podiatrist" synonymous with chiropodist.

## MEDICAL ECONOMIC ABSTRACTS

THE CHANGING ASPECT OF AGE  
AT DEATH

A somewhat novel arrangement of mortality rates is given in the accompanying table, which was prepared by William C. Welling and published in the *Connecticut Health Bulletin* (52:291 [Nov.] 1938). This shows in a striking manner just how and within what age limits the death rate has been reduced

*Mortality by Age Groups, 1890-1937*  
(Percentage of total deaths in italics)

Ages	1890	1900	1910	1920	1930	1937
Under 1	2 540 <i>18.6</i>	3 521 <i>21.6</i>	3 472 <i>19.9</i>	3 063 <i>16.2</i>	1 529 <i>9.1</i>	907 <i>5.2</i>
1 5	1 162 <i>8.6</i>	1 294 <i>8.0</i>	1 234 <i>7.1</i>	1 349 <i>7.1</i>	431 <i>2.6</i>	213 <i>1.2</i>
5 10	414 <i>3.0</i>	393 <i>2.4</i>	357 <i>2.0</i>	423 <i>2.2</i>	209 <i>1.2</i>	150 <i>0.8</i>
10 20	645 <i>4.7</i>	696 <i>4.3</i>	576 <i>3.3</i>	622 <i>3.3</i>	467 <i>2.8</i>	329 <i>1.9</i>
20 30	1 249 <i>9.2</i>	1 172 <i>7.2</i>	1 037 <i>5.9</i>	1 298 <i>6.9</i>	763 <i>4.5</i>	565 <i>3.2</i>
30 40	1 104 <i>8.2</i>	1 247 <i>7.7</i>	1 447 <i>8.3</i>	1 608 <i>8.5</i>	1 019 <i>6.0</i>	807 <i>4.6</i>
40 50	1 053 <i>7.7</i>	1 214 <i>7.5</i>	1 474 <i>8.4</i>	1 580 <i>8.4</i>	1 615 <i>9.6</i>	1 645 <i>9.4</i>
50 60	1 163 <i>8.5</i>	1 497 <i>9.2</i>	1 709 <i>9.8</i>	2 107 <i>11.0</i>	2 442 <i>14.5</i>	2 670 <i>15.2</i>
60 70	1 528 <i>11.2</i>	1 805 <i>11.0</i>	2 243 <i>12.9</i>	2 574 <i>13.6</i>	3 311 <i>19.6</i>	3 951 <i>22.5</i>
70 80	1 532 <i>11.2</i>	1 954 <i>12.0</i>	2 388 <i>13.7</i>	2 602 <i>13.8</i>	3 189 <i>18.9</i>	3 873 <i>22.0</i>
80 90	988 <i>7.3</i>	1,267 <i>7.8</i>	1 310 <i>7.5</i>	1 450 <i>7.7</i>	1 612 <i>9.5</i>	2 108 <i>12.0</i>
90 100	247 <i>1.8</i>	213 <i>1.3</i>	207 <i>1.2</i>	243 <i>1.3</i>	295 <i>1.7</i>	345 <i>2.0</i>
Unknown age	40	95	46	6	90	11
Total deaths	13 665	16 368	17 500	18 925	16 972	17 574
Av. age at death	38.2	38.1	40.7	42.4	52.8	58.6

It is somewhat significant that some of these rates of change seem to be accelerating during the last decade. Up to and including 1920 the entry of greatest numerical value was the infant mortality. By 1930 this had abruptly changed to the age group 60-70. In 1890 and 1900 the median death rate fell somewhere within the age group 30-40. In 1910 and 1920 the median age at death was between 40-50 years and in 1937 this had increased to the age group 60-70.

MORBIDITY AND PHYSICIANS' INCOMES  
UNDER GERMAN SICKNESS  
INSURANCE

The perennial conflict over the payment of physicians in Germany has brought out some additional and illuminating statistics concerning morbidity among the insured. J. Seifert in an article on "Morbidity, Wage Movements and Income of the Insurance Physicians in the Legal Insurance Societies," which appears in the *Deutsches Arzteblatt* (68:893 [Dec. 24] 1938), replies to charges raised by some of the administrators of sickness insurance that the physicians are receiving increased salaries.

He points out, in the first place, that one of the elements which enter into the calculation of the physician's compensation is the number of sicknesses annually. These have increased steadily and at a quite rapid rate in recent years, so that the work which the physician is required to do has become such that "the practicing physician knows no regular hours of work, day and night and hour after hour he must be ready to serve. He is generally overloaded with work." The increase in morbidity has brought about a condition in which the rate of payment for insurance services is lower from year to year. This is in part due to the demand for more extensive services, for

which no additional payment is provided. The demand for x-ray examinations and other costly and time-consuming services has greatly increased. At the same time the "insurance societies find it impossible to pay any higher rates to physicians because no resources for that purpose are available. It is useless to make demands on the societies to raise the rate of payment, since the societies cannot meet any such demand. It is a very exceptional situation when the societies can raise the dues of their members." This condition is one that is bound to arise in any system of voluntary or compulsory insurance in which premiums are paid in cash and benefits in services.

The situation has been rendered exceptionally critical in Germany by the recent rapid increase in the morbidity of the insured. This increase has been fairly constant for fifty years and the rate of advance has risen since 1933. In 1933 the average number of sicknesses per person insured was 2.32, in 1936 this was 2.79, an increase of 20.3 per cent. (This figure applies to a complete, individual illness, which may require many treatments.) The Committee on the Costs of Medical Care found that the corresponding figure in the United States was "0.84 illnesses per person."<sup>1</sup> In other words, the morbidity among persons able to work and therefore covered by insurance in Germany was more than three times as high as for the entire population in the United States, including infants, the aged and the chronically disabled.

The author of the article from which this material was taken is sharply aware of the use that might be made of these figures by critics of the present totalitarian state in Germany, and he seeks to explain it on the ground that the removal of all restrictions on access to services of insurance physicians has caused the greater use of medical services. He seemingly overlooks the argument which might, even for his purposes, have been equally effective and which has been previously mentioned—that this increase has been cumulative for half a century.

In spite of the increase in illnesses which are treated in the home, the author still complains that the costs of hospitalization "have been rising for many years, for which the insurance physician is mainly responsible, since he sends more and more of the insured and their dependents to the hospital in order not to increase the number of services delivered in the home and thereby reduce the rate of payment for such services."

## HEALTH PERSONNEL IN GERMANY

The results of an annual enumeration of all persons concerned in the care and treatment of disease in Germany are given in the *Deutsches Arzteblatt* (68:903 [Dec. 24] 1938). The following table summarizes the results of this enumeration.

Occupation	Number of Persons			
	1934	1935	1936	1937
Licensed physicians*	47,210	47,419	47,844	48,549
Approved dentists	11,247	12,088	13,037	13,966
Licensed druggists	10,845	10,981	11,461	11,549
Pharmaceutical assistants	5,269	4,791	4,591	4,641
Midwives	25,911	25,737	25,765	25,143
Dental mechanics (dentisten)	19,998	20,009	20,659	21,000
Physical therapists and bath attendants	11,410	11,922	12,140	12,687
Nurses	120,216	126,068	131,249	131,407
Nurses for infants and small children	5,747	6,569	9,302	9,781
Private duty nurses	1,197	1,240	1,333	1,517
Sanatoriums	4,972	5,581	5,700	5,847
Unlicensed healers	14,266	14,023	12,936	12,101
Total	278,353	286,948	296,166	298,540
Male	129,019	130,520	132,322	133,710
Female	149,334	156,428	163,844	164,830

\* This includes only practicing physicians and excludes those who have retired, are engaged in research, hold official positions or are in military service. The total number of physicians included within the official medical organization (Reichsarztzammer) is 50,443.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

### CALIFORNIA

**Physicians' Art Exhibit**—The San Francisco branch of the American Physicians' Art Association held an art exhibit in the club rooms of the San Francisco Medical Society, Washington and Laguna streets, February 13-17. On the opening night there was a Valentine dinner dance given by the woman's auxiliary at the county medical building.

**Professor Van Dyke to Retire**—Dr Edwin C. Van Dyke, since 1913 member of the faculty of the College of Agriculture of the University of California, Berkeley, will retire at the end of the present college year. He will reach the retirement age April 7. Dr Van Dyke graduated at the Cooper Medical College, now Stanford University School of Medicine, in 1895. He engaged in the private practice of medicine until 1913, when he joined the California faculty as instructor in entomology. He has been professor since 1927. He is a former president of the Pacific Coast Entomological Society and is the honorary curator of the California Academy of Science.

**Society News**—The Los Angeles County Medical Association devoted its meeting February 2 to a discussion of new drugs, the speakers were Drs Barclay E. Noble, Morris H. Nathanson, Clarence W. Olsen, William C. Boeck, Robert W. Lamson, Clinton H. Thienes, Roy E. Thomas and William J. Mitchell Jr.—Dr John Dunlop, Pasadena, among others, discussed "Transcondylar Fractures of the Humerus in Children" before the Los Angeles Surgical Society February 10.—At a meeting of the Pacific Physical Therapy Association January 25 Drs Clinton D. Hubbard, Huntington Park, spoke on "Morbose Effect of Stercorremia" and William W. Worster, San Gabriel, "Advantages of Underwater Treatment in Poliomyelitis."

### DISTRICT OF COLUMBIA

**Personal**—Dr Ross T. McIntire, surgeon general of the U. S. Navy, has been appointed a member of the advisory board of the Society for the Prevention of Asphyxial Death, succeeding Dr Perceval S. Rossiter, recently retired.—Dr Robert B. Hightower, Richmond, Va., has been appointed assistant hygiene director in the public schools of Washington.

**Doctors' Hospital**—Ground was broken for the new \$1,500,000 Doctors' Hospital January 9 by Dr Charles Stanley White, president of the institution. The building will be ten stories high and will provide accommodations for 250 patients. It will connect the two medical buildings, known as the Washington and Columbia Medical Buildings, which have as tenants about 250 physicians and representatives of the allied professions.

**Society News**—Dr James G. Townsend, director of health for the Indian Service, was reelected president of the District Tuberculosis Association recently, and Dr J. Winthrop Peabody, superintendent Tuberculosis Sanatorium was chosen secretary.—Dr Charles F. Geschickter, Baltimore, discussed "Recent Advances in Endocrinology in Relation to Neoplastic Diseases" before a meeting of the medical and dental officers of the navy on duty in the District and vicinity February 6.

### FLORIDA

**Hospital News**—The new Lee Memorial Hospital, Fort Myers, assured by a \$100,000 WPA project will be located in Edison Park, according to the state medical journal.

**Public Health Survey**—The American Public Health Association through its committee on state health studies was to begin a statewide public health survey in Florida January 3. The Commonwealth Fund is supplying the funds. The results of the study will form the basis of a long time program of public health work in the state newspapers reported.

**Society News**—The Duval County Medical Society was addressed in Jacksonville January 3 by Drs Karl B. Hanson, James G. Laverle and Julian E. Gammon on "Fluid Balance" and Carl C. Mendoza, New Technics in Blood Transfusion.—The Suwannee River Medical Association was addressed

in Lake City January 20 by Dr John F. Busey Jr. on the value of electrocardiograms, Dr James F. Pitman presented a case report on complete transposition of viscera. Both speakers are of Lake City.

### GEORGIA

**Dr Newburgh Lectures**—Dr Louis H. Newburgh, professor of clinical investigation and internal medicine, University of Michigan Medical School, Ann Arbor, delivered a series of lectures before the Atlanta Clinical Society February 8-10, on "Methods for Studying Exchange of Water Between the Human Organism and the Environment," "Physiology of Water and Salt Exchange" and "Pathological Shifts in Water and Salts as Exemplified by Quantitative Study of These Conditions in Patients."

**Society News**—At the sixth annual meeting of the Georgia Pediatric Society in Augusta, January 12, Drs Charles Hendee Smith, New York, discussed "The Diet of Infants and Young Children", Alexis F. Hartmann, St. Louis, "Nephritis," and Thomas B. Cooley, Detroit, "Anemias of Infancy." At a joint meeting of the society and the Richmond County Medical Society the same evening Dr Cooley spoke on "The Constitutional Anemias of Childhood", Dr Hartmann, "Some Physiologic Effects of Sulfanilamide," and Dr Smith, "Pneumonia."—Dr Charles M. Mulhern, Augusta, addressed the Dugas Journal Club in Augusta January 16 on "Analysis of 500 Incomplete Abortions: Radical versus Conservative Treatment," and Dr Edward S. Cardwell Jr., Augusta, "Syphilis of the Kidney."

### IDAHO

**Changes in Health Officers**—Dr Max B. McQueen, Pocatello, has been appointed head of the health district which includes Nez Perce, Latah and Clearwater counties with headquarters at Lewiston. He succeeds Dr Marion W. Caskey, who will enter private practice. Dr Herbert L. Newcombe, Boston, has been appointed in charge of the health unit in Kootenai to succeed Dr Lester C. Krotcher, Boise, who has been named to a position with the state department of health. Dr George H. Bischoff, Boise, has been given a temporary appointment as head of the Bannock County health unit, succeeding Dr Glen T. Smith, who resigned to accept a hospital residency in Chicago, according to *Northwest Medicine*.

### ILLINOIS

**Prevalence of Tularemia**—Because of the increased prevalence of tularemia in Illinois during the past season, the state conservation department's plan to move 5,000 rabbits from the southern counties to farm lands and marshes in the northern part has been abandoned. More than thirty-eight deaths from tularemia were reported in the state during the past year and 489 cases of the disease have been recorded since Jan. 1, 1938, newspapers announced January 19.

**Activities for Crippled Children**—There were 1,744 patients seen in the sixty clinics for crippled children held in thirty different sites in Illinois in the fiscal year 1937-1938, according to a recent report of the division for handicapped children, state department of public welfare. Of 783 patients recommended for hospital care, 45.6 per cent were hospitalized during the fiscal year, while the majority of the group had been hospitalized by Dec. 1, 1938. A program of consultation on poliomyelitis was initiated and was in operation during the summer of 1938 in the entire state except within the city limits of Chicago, where other agencies covered the field. All the sporadic cases of poliomyelitis of 1938 that needed hospital care were sent to hospitals. There were but twenty-five bona fide cases during the summer. The field nurses of the division for handicapped children made 10,410 visits during the year and 51,960 days of hospital care were provided to crippled children by the department of public welfare of these children 8,426 were in the wards of the general hospitals of the state where orthopedic surgeons are cooperating in the plan for this care with the division for handicapped children. Appliances were furnished to patients attending the clinics in the following numbers: braces 138, artificial limbs 39, and orthopedic shoes and shoe corrections 184.

### Chicago

**Chevalier Jackson to Give Public Lecture**—The Chicago Medical Society will present a public lecture March 1 at the Chicago Woman's Club by Dr Chevalier Jackson, professor of bronchoscopy, Temple University School of Medicine, Philadelphia, on "Looking Into Your Lungs."

**Society News**—The Chicago Gynecological Society was addressed January 20 by Drs William J Dieckmann and Ira Brown on "The Obstetric Management of Pregnancy Toxemia" and Charles E Galloway and Tom D Paul, Evanston, Ill., "Treatment of Early Abortions"—At a meeting of the Chicago Society of Internal Medicine January 23 the speakers included Dr Frederick T Jung and B L Isaacs on "Measurement of Vitamin A Deficiency in Man" and Dr John Ashworth, C J Farmer M A, and Dr Don C Sutton, "Observations on Vitamin C"—The mortality of appendicitis was discussed in a symposium before the Chicago Medical Society February 1, the speakers were Drs David E W Wenstrand, medical director, Northwestern Mutual Life Insurance Company, Milwaukee, LeRoy H Sloan, professor of medicine, University of Illinois College of Medicine, and Vernon C David, clinical professor of surgery, Rush Medical College Dr Byrl R Kirklin, Rochester, Minn, addressed a joint meeting of the society and the Chicago Roentgen Society January 18 on "The Value of Roentgen Diagnosis as It Pertains to the Physician in General Practice," and Dr Bernard P Widmann, Philadelphia, "X-Ray, Radium and Cancer" The Chicago Medical Society sponsored a public lecture at the Chicago Woman's Club February 8 with Dr Francis E Sencar, professor of dermatology, University of Illinois College of Medicine as the speaker, his subject was "Preserving Your Complexion"

### INDIANA

**County Secretaries Retire**—The Lake County Medical Society held a testimonial dinner meeting January 12 in honor of Dr Eldridge M Shanklin, Hammond, who has retired as secretary of the society Dr Shanklin served from 1912 to 1920, becoming president in the latter year In 1927 he took office as secretary, serving continuously through 1938 He has been succeeded by Dr Harry Brandman, Whiting—Dr Joseph L Allen, Greenfield, who has been secretary of the Hancock County Medical Society since 1928, has retired He is succeeded by Dr James R Woods Jr, Greenfield

**Society News**—At a meeting of the Tippecanoe County Medical Society in Lafayette recently Dr Samuel M Fernberg, Chicago, spoke on "Newer Developments and Common Misconceptions of Allergy"—A symposium on jaundice was presented before the Indianapolis Medical Society recently by Drs Brandt F Steele, Bernard D Rosenak and Ralph U Leser—The Northeastern Indiana Academy of Medicine was addressed in Kendallville recently by Dr Henry F Beckman, Indianapolis, on "Hemorrhage Associated with Labor"

**Personal**—Dr Charles E Holland has been appointed physician at Indiana University, Bloomington, succeeding his father, the late Dr James E P Holland—Dr William F Duncan, Aurora, has been appointed the first honorary life member of the Dearborn-Ohio County Medical Society Dr Duncan is the oldest member of the society and has practiced medicine in Manchester for forty-six years He graduated at Miami Medical College, Cincinnati, in 1892—Mrs Isaac Born, Indianapolis, has been appointed commander of the Indiana division of the Women's Field Army of the American Society for the Control of Cancer, succeeding Mrs George Dillinger, French Lick, resigned

### IOWA

**Itinerant Scissors Grinder with Smallpox**—A warning was issued throughout the state January 19 when an itinerant scissors grinder was found suffering from smallpox, newspapers reported January 20 The patient said that he stopped at barber and beauty shops in Mount Pleasant, Ottumwa, Columbus Junction and Iowa City to sharpen scissors, stayed in hotels, ate in restaurants and rode with motorists between towns, it was reported He was detained at University Hospital, Iowa City

### MASSACHUSETTS

**Alumni Dinner**—The alumni of Boston University School of Medicine met at dinner at the Hotel Somerset, Boston, January 20 The speakers included Drs Nathan H Garrick, president of the alumni association, Samuel N Vose, chairman, Alexander S Begg, dean of the university, Wesley T Lee, alumni chairman of the school of medicine campaign, Morris Fishbein, Chicago, editor of THE JOURNAL, "The Frontiers of Medicine", Lucv J Franklin, L H D, dean of women, Boston University, Frederick W Mansfield, LL D, chairman of the Boston University general alumni committee, Pliny Jewell, trustee of the university, and Walter B Dickinson, campaign manager

**Special Society Meetings**—Dr Elias William Abramowitz, New York, addressed the New England Dermatological Society in Boston February 8 on "Action of Certain Drugs in the Local and General Treatment of Various Dermatoses"—At a meeting of the New England Society of Physical Medicine in Boston, January 18, Dr Edward A Edwards discussed "Organic Arterial Disease"—The New England Heart Association was addressed in Boston January 23, among others, by Drs Blair V Jager on "Thrombosis of the Ductus Arteriosus with Embolic Manifestations" and Paul Kunkel, "Influence of the Peripheral Circulation in the Upper Extremities on the Circulation Time as Measured by the Sodium Cyanide Method"—Dr Paul A Younge discussed "Pre Invasive Carcinoma of the Cervix Uteri" before the New England Pathological Society January 19 in Boston

### MINNESOTA

**Graduate Courses at Center for Continuation Study**—Graduate courses at the Center for Continuation Study of the University of Minnesota, Minneapolis, include the following

Hospital Administration January 23 28  
Medical Record Librarians January 30 February 1  
Hospital Dietetics for Dietitians February 13 15  
Medical Social Work February 22 24  
Orthopedics March 13 18  
Neuropsychiatry March 13 18  
Diagnostic Roentgenology March 20 25

In the spring courses on obstetrics, general surgery, hematology and gastro enterology will be offered, the dates to be announced later One on ophthalmology was presented January 16-21

**Society News**—The East Central Minnesota Medical Society was recently addressed by Drs Erling S Platou, Minneapolis, on "Convalescent Sera as Therapeutic Agents," and Gordon R Kimman, St Paul, "Neurosis"—Dr Moses Barron, Minneapolis, was recently elected president of the Minnesota Society of Internal Medicine, Dr Russell M Wilder, Rochester, vice president, and Dr Max H Hoffman, St Paul, was reelected secretary-treasurer The spring meeting will be in Minneapolis—Dr Hobart C Johnson, North Mankato, who has been a medical missionary for several years, discussed "Practice of Medicine in Africa" before the Nicollet Le Sueur County Medical Society in Le Sueur recently—The Upper Mississippi Medical Society was addressed in Brainerd January 28, among others, by Drs Chester A Stewart, Minneapolis, on "Nutritional Problems in Infancy" and Orwood J Campbell, Minneapolis, "Some Observations on the Care of Fractures"—Dr William J Kerr, San Francisco, gave a Mayo Foundation lecture in Rochester Dec 15 1938, on "The Anxiety States in Practice with Particular Reference to the Physiologic and Biochemical Disturbances"

### MISSOURI

**New County Health Center**—A two story building will be erected at the St Louis County Hospital, Clayton to serve as headquarters for the county health department There will be eight rooms on the first floor and a large waiting room and consultation rooms on the second floor The county court has appropriated \$16 500 toward the \$30,000 cost of the building, while the remainder will be sought from the PWA, according to the state medical journal The U S Public Health Service has promised a grant of \$2,500 The health department, of which Dr Theodore R Meyer is the director, is now housed in four rooms scattered through the hospital

**Society News**—Jackson County Medical Society, Kansas City, recently reported the 100 per cent payment of membership dues—Dr Andrew C Ivy, Chicago addressed the Kansas City Obstetrical and Gynecological Society January 19 on "Physiology of Uterine Muscle in Labor"—The Ray County Medical Society was addressed in Hardin in December by Drs William Byron Black and Ralph R Coffey, Kansas City, on "Relationship of Nasal Allergy and Sinusitis" and "Abdominal Pains" respectively—At a meeting of the Kansas City Surgical Society January 18 Dr Michael J Owens, among others, spoke on "Use of Barbiturates in Surgery"

### NEBRASKA

**District Meeting**—Lincoln physicians addressed a meeting of the Sixth Council District of the Nebraska State Medical Association in Staplehurst recently as follows Drs Harry E Flansburg, on "Pulmonary Infarction", E Burkett Reed "The Mechanism of Anemia," and Clarence C Hickman "Diagnosis and Treatment of Certain Anorectal Conditions"

**Practitioner Honored**—Dr and Mrs Joseph H Downing Rising City, were guests at a dinner given by the Sixth Councilor District and the Butler County Medical Society January 9 at Brannard Dr Charles W M Poynter, dean of the University of Nebraska School of Medicine, Omaha, was the principal speaker, reviewing the history of medical practice in Nebraska Drs Homer Davis, Genoa, president of the Nebraska State Medical Association, and Arthur L Miller Kimball, president-elect, paid tribute to Dr Downing, who has practiced fifty-six years in the state

## NEW YORK

**Foreign Physicians Qualify for Licenses**—Of 1 063 foreign physicians who took the state medical examinations in January, 622 were successful The largest number of candidates (422) came from Germany, of whom 210 failed to pass Austria furnished 112 candidates, of whom thirty-five failed Of 488 graduates of New York medical schools 55 per cent failed and of 285 from schools of other states 249 per cent failed

**Dr Edward R Baldwin Retires**—Dr Edward R Baldwin, Saranac Lake, for many years director of the Trudeau Foundation and the Trudeau School of Tuberculosis has retired and has been succeeded by Dr Leroy U Gardner, director of the Saranac Laboratory Dr Baldwin, now 74 years old, was born in Connecticut and graduated from Yale University School of Medicine in 1890 He went to Saranac Lake in 1893 and was assistant director of the Saranac Laboratory from that year till 1915 when he became director He has been head of the foundation and the school of tuberculosis since 1916 In 1916 Dr Baldwin was president of the National Tuberculosis Association He has also served as president of the American Clinical and Climatological Association In 1936 he received the Kober Medal

## New York City

**Theobald Smith Lecture**—Dr Richard P Strong, professor of tropical medicine emeritus, Harvard University Medical School, Boston, delivered the Theobald Smith Lecture before the New York Society of Tropical Medicine January 20, on "Malarial Diseases in the Western Hemisphere"

**Health Data for 1938**—The number of deaths in New York in 1938 was 73,775, giving a rate of 9.8 per thousand, the lowest in the city's history Last year the rate was 10.4 For the first time infant mortality reached a low rate of 38.3 per thousand live births The maternal death rate was 3.5 per thousand live births In 1933 it was 6.4 Dr John L Rice, health commissioner in presenting the report attributed the reductions in deaths of mothers and infants to the work done by the county medical societies and the New York Academy of Medicine in cooperation with the health department The rate from diphtheria was 17 per hundred thousand children under 15 years old there were 712 cases with twenty-seven deaths Scarlet fever cases and deaths declined, but measles and whooping cough were unusually prevalent An increase in measles was not unexpected, as 1937 was a light year, there were 34,605 cases with forty-two deaths Whooping cough was nearly three times as prevalent as in the previous year with 12,333 cases and 105 deaths Poliomyelitis and meningitis were at a low point, with forty-four and 112 cases, respectively A reduction in mortality from pneumonia was tentatively attributed to new services for distribution of serum to physicians There were 4,732 deaths compared with 6,504 in 1937 The death rate from tuberculosis was 51.1, a decline from 57.4 of the previous year Typhoid fever caused twenty-three deaths compared with an average of 126 during the decade 1920-1929 The death rate from appendicitis was 11.1 and for 1937 was 12.6 In 1930 it was 16 Deaths from accidents have declined in the past year the rate for all accidents being 50 as compared with 56.3 for 1937 Suicides numbered 1,161 in 1938 more than in 1937 when 1,140 were listed There were 303 homicides seventy-three less than in 1937 The birth rate continued to decline being 13.6 per thousand of population compared with 13.7 in 1937 and 17.7 in 1930

## NORTH DAKOTA

**Personal**—Dr Ernst G Sasse Lidgerwood was recently guest of honor at a dinner given by friends in recognition of his forty years service to the community—Dr George H Hiltz Bowhells, has been appointed health officer of Burke County

## PENNSYLVANIA

**Cancer and Diabetes Made Reportable**—The state department of health recently announced new regulations making cancer and diabetes reportable diseases Previously these diseases were registered only when they were fatal

**County Secretaries' Conference**—The thirty-second annual conference of secretaries and editors of county medical societies was held in Harrisburg February 10 After separate meetings of secretaries and editors there was a discussion of group hospitalization insurance Dr Walter F Donaldson Pittsburgh, secretary of the Medical Society of the State of Pennsylvania, spoke on "Federal Health Legislation" and afterwards the group discussed Pennsylvania's new public assistance medical service and state and county plans for voluntary insured medical service

## Philadelphia

**Medicolegal Night**—The Philadelphia County Medical Society presented a "Medicolegal Night" for its program February 8 with a discussion of "The Role of Psychiatry in Criminal Justice" The speakers were Prof Edwin R Keedy, LL.D., University of Pennsylvania, on "Proposals of Legislation Relative to the Presentation of Psychiatric Findings in Criminal Procedure", Hugh D Scott, assistant district attorney, "The Prosecutor and Psychiatry", Thomas E Cogan, public defender's office, "The Public Defender and Psychiatry", and Judge Ralph H Smith, Pittsburgh The Allegheny County Behavior Clinic" Dr Edward A Strecker professor of psychiatry, University of Pennsylvania School of Medicine, and Judge Curtis Bok were the commentators on the addresses

**Society News**—Dr Cyril N H Long, New Haven, Conn., delivered a Nathan Lewis Hatfield Lecture before the College of Physicians of Philadelphia February 1 on "Diabetes Mellitus in the Light of Our Present Knowledge of Metabolism"—Dr Howard C Taylor Jr, New York, addressed the Obstetrical Society of Philadelphia February 2 on "The Endocrine Factor in Neoplastic Disease of the Reproductive Tract"—At a meeting of the Philadelphia Academy of Surgery February 6 the speakers were Drs John C Howell and Harry G McNamee Jr on "Treatment of Breast Cancer" and Drs Lewis K Ferguson and Wesley D Thompson Jr, Internal Derangement of the Knee Joints A Review of 100 Operated Cases with Follow-Ups"—Dr Joseph C Yaskin delivered his presidential address before the Philadelphia Neurological Society January 27 on "Neurological Complications Arising from Infections of the Temporal Bone and Paranasal Sinuses"

## GENERAL

**"Milligrams per Cent" a Vague Term**—Many authors use in their papers the terms 'milligrams per cent' or 'grams per cent' to express the results of some laboratory investigations These terms are vague and unreliable The unit used should be specified such as milligrams per hundred cubic centimeters or milligrams per hundred grams

**Society News**—Dr John Edward Clark, Seattle was recently elected president of the Puget Sound Academy of Ophthalmology and Otolaryngology Dr W Cameron Tacoma, was elected vice president and Dr Purman Dorman Seattle secretary-treasurer—The thirty-first annual meeting of the American Society for Pharmacology and Experimental Therapeutics, will be held in Toronto Ont, at the Royal York Hotel April 26-29 The secretary is Dr Gustave P Grabfield 319 Longwood Avenue Boston

**International Surgeons' Meeting**—The biennial assembly of the International College of Surgeons will be held in New York at the Hotel Roosevelt May 21-24, under the chairmanship of Dr Andre Crotti Columbus, Ohio international president Applications for places on the program should be sent to Dr Fred H Albee 57 West Fifty-Seventh Street New York General information as to scientific and commercial exhibits may be obtained by addressing Dr Edward Frankel Jr, 217 East Seventeenth Street New York

**Fatal Accidents Declined in 1938**—Eleven thousand fewer people were killed in accidents of all kinds in the United States during 1938 than in 1937, a decline of more than 10 per cent according to the *Statistical Bulletin* of the Metropolitan Life Insurance Company The 1938 loss was the lowest since the deep depression years of 1932 and 1933 when the number of deaths totaled 89,000 and 91,000 respectively it was stated Present indications are that the number of deaths resulting from accidental injuries will run around 95,000 in 1939 as compared with approximately 106,000 deaths in 1937 and with 110,000 deaths the all time high figure in 1936 That business conditions clearly have a material effect on the general accident

toll is evidenced by the low totals during the depression years. Motor vehicle fatalities decreased about 8,000, or from about 40,000 in 1937 to between 31,000 and 32,000 deaths in 1938, although data on gasoline consumption indicate little change in the amount of automobile mileage in the last two years. There was little change in accidents in and about the home as compared with 1937, final records probably showing that home accident fatalities during 1938 exceeded in number those resulting from motor vehicle accidents. According to the bulletin, cataclysms and catastrophes claimed large numbers of lives in all sections of the country during the year. Most devastating were the hurricane and flood in the Atlantic Coastal states in September (682 lives) and the floods in southern California during February and March (181 lives). A tornado originating in Oklahoma spread across Kansas, Arkansas, Missouri and Illinois (forty lives). Other disastrous tornadoes occurred in Charleston, S C (twenty-nine lives), in Rodessa, La, (twenty-five lives), in and near Belleville, Ill (twenty-two lives), in Aliceville, Ala (thirteen lives), and in Clyde, Tex (thirteen lives). Flood waters caused thirteen deaths in Whitestone, Ga, and ten in Havre, Mont. Forty-seven persons were killed in the most serious railroad accident in years when a passenger train plunged through a bridge in Montana. This one accident took as many or more lives among passengers as are lost ordinarily in all railroad passenger accidents in an entire year. Accidents causing ten or more deaths included coal mine explosions in Grundy, Va (forty-five lives) in Pittston Township, Pa (ten lives), and in Harwick, near Pittsburgh (ten lives), a fire in a hotel in Atlanta, Ga (thirty-five lives), the collision of a school bus and freight train in Midvale, Utah (twenty-four lives), the collapse of a cafe building in Phenix City, Ala (twenty-one lives), the vanishing of the Hawin Clipper with fifteen persons aboard, the airplane crashes near Bozeman, Mont (ten lives), near Cleveland, Ohio (ten lives), and off San Diego, Calif (eleven lives), the collision of two passenger trains near Niland, Calif (twelve lives), and the premature explosion of dynamite while workers were blasting a tunnel in Baltimore (ten lives). Hundreds of other persons were victims in multiple fatality accidents of from five to ten deaths.

## Government Services

### Recommendations of Advisory Committee on Maternal and Child Health Services of U S Children's Bureau, Dec 3 and 4, 1938

The following members of this Committee, at the meeting in Washington Dec 3-4 1938, made these recommendations in addition to those made in 1936 and 1937

Fred L. Adair MD Chicago  
Horton R. Casparis MD Nashville  
Hazel Corbin RN New York  
Robert L. DeNormandie MD Boston  
Amelia Grant RN New York  
Clifford G. Grulee MD Evanston Ill  
Henry F. Helmholtz MD Rochester Minn  
George W. Kosmak MD New York  
George M. Lyon MD Huntington W Va  
Lyle G. McNeile MD Los Angeles  
Guy S. Millberry DDS San Francisco  
Mary E. Murphy Chicago  
Harry S. Mustard MD New York  
Everett D. Plass MD Iowa City  
Grover F. Powers MD New Haven  
Lydia J. Roberts Chicago  
Viola Russell MD Pierre S D  
Marian W. Sheahan RN Albany N Y  
Clifford D. Sweet MD Oakland Calif  
Felix J. Underwood MD Jackson Miss  
Philip F. Williams MD Philadelphia

Dr Paul A. Teschner, Chicago, represented the American Medical Association at this meeting

#### I Selection, training, and compensation of personnel

1 The advisory committee, recognizing that efficient administration of the maternal and child-health services depends on the employment of fully qualified personnel and that personnel with such qualifications are not always resident within each state, urges that (1) selection of personnel be on the basis of qualifications only and (2) that salaries commensurate with the qualifications required and services performed be paid.

2 It is the sense of this committee that the American Medical Association be asked to use its influence through its various component societies to promote the acceptance and attainment of desirable standards regarding qualifications of all official

personnel in health departments, and to work to the end that merit systems be established in all states and political subdivisions.

3 The committee recommends that physicians and nurses participating in maternity clinics and child-health conferences under the maternal and child-health programs be given special training for this type of service and that continued supervision and consultation by approved specialists in these fields be provided by state health authorities to maintain adequate standards of obstetric and pediatric service.

4 The committee recommends that the qualifications of directors of maternal and child-health divisions be (1) Graduation from medical schools approved by the Council on Medical Education and Hospitals of the American Medical Association, (2) thorough training in pediatrics or obstetrics or both preferably training and experience required for certification by the American Board of Pediatrics or of Obstetrics and Gynecology, (3) eligibility for examination for medical licensure in the state in which service is to be rendered, (4) preferably, training in the fundamentals of public health.

5 The committee recommends that the same fundamental requirements be recommended for assistant directors except that less stress be placed on administrative experience.

6 The committee recommends that local practicing physicians paid from maternal and child-health funds for services in child-health or maternity clinics and conferences (1) shall be licensed to practice in the state, (2) shall be graduates of medical schools approved by the Council on Medical Education and Hospitals of the American Medical Association, (3) should be devoting a considerable proportion of their practice to pediatrics or obstetrics, and (4) should have had or shall receive special training in the conduct of these clinics and should be selected from among the outstanding practitioners of obstetrics or pediatrics in their communities.

7 To qualify as full-time clinical consultants in obstetrics or pediatrics or other specialty, physicians should be certified by their respective American boards or have had the training and experience required for certification by the American boards of their respective specialties and, in addition, have had experience in the practice of medicine.

To qualify as part-time clinical consultants in obstetrics or pediatrics under the maternal and child-health programs practicing physicians should be certified by the respective American boards or have had the training and experience required for certification by the American boards of their respective specialties. If physicians having such qualifications are not available, the state health agency, after consultation with a committee of physicians appointed by the state health officer to advise on the selection of physicians, should designate the physicians best qualified to serve as clinical consultants in obstetrics or pediatrics (or other specialty).

#### II Cooperation with other agencies

Recognizing the need for technical advice in the development of the maternal and child-health programs in the states, the committee recommends that the state health agency administering the maternal and child-health program make use of expert advice available through such professional groups as the state maternal and child-welfare committees, state organizations of public-health nurses, social workers, nutritionists, or other professional groups, and through physicians certified by, or having the training and experience required for certification by, their respective specialty boards, or through other individuals with special interest in and knowledge of the problems of maternal and child health.

#### III Hospital standards

The committee recommends that the Children's Bureau take steps to secure the cooperation of various professional and administrative groups and of the state health departments in formulating standards for hospitals and maternity homes caring for mothers, infants and children and that attempts be made by securing effective state licensure of hospitals and maternity homes and by other means to establish and maintain hospitals which conform to acceptable standards of care for mothers, infants and children.

#### New Veterans' Facilities Opened

A new Veterans Administration Facility and regional office was recently opened at White River Junction, Vt., three stories high with fifty beds for surgical patients and sixty for general medical patients. Dr. Jefferson W. Pafford, transferred from Newington, Conn., is chief medical officer. Construction of another building to provide seventy-seven additional beds has been begun. A new 500 bed hospital at Kecoughtan, Va., was also opened in October to replace an old building.

#### The Control of Puerperal Fever

In a lecture at the London School of Tropical Medicine and Hygiene Dr Leonard Colebrook, honorary director of the Research Laboratories, Queen Charlotte's Hospital, said that ten years ago the campaign against maternal mortality was held up by lack of knowledge but today the difficulty was that more facts had been accumulated than could be used. Of 100 cases of puerperal fever, the condition was due in about forty to the hemolytic streptococcus and in the other sixty to different organisms, mostly following injury during labor. He would say little about the second group because until to a large extent injuries during childbirth could be obviated they would persist.

Infection by the hemolytic streptococcus was the more important because it was the most serious and the most easily preventable. There were six or seven different types of the organism which could be distinguished by biochemical and serologic tests, but only one of these was responsible to any extent for puerperal fever. It might be transferred from other patients by the physician or nurse but it certainly came by way of the air in particles of dust or droplets from the throat, which were the most important sources. Dr Dora Colebrook investigated forty-eight cases in which she had been able to identify the organism found in the mother with that from some outside source. In twenty-four the infection came from an attendant contact, physician or nurse, and in all but one it was of the respiratory tract. Of the other cases, the infection came in nine from a member of the mother's household and in six from the mothers themselves.

Were so-called healthy throats dangerous? Research had shown that sometimes they might be a source of infection. It seemed that from 5 to 10 per cent of people were carriers of this type of streptococci. Nasal infections appeared to be less frequent but they were serious. A person suffering from a sinus infection always had a little discharge and only a small degree of lack of care was necessary for the infection to be carried.

#### PREVENTIVE METHODS

With all these possibilities it was difficult to get complete safety in midwifery. The ideal would be to inoculate all women in the last month of pregnancy, but at the moment such a measure was not in sight. However, many other things could be done. It should be possible to erect barriers by the use of masks and strict antiseptic toilet. Some valuable things had been learned with regard to antiseptics in the last few years. The prime importance of soap and water had been established. This was the most valuable antiseptic ritual both in surgical procedures and in midwifery. The old antiseptics did not give a sufficient margin of safety when removing streptococci from the skin. It had been shown that iodine and the halogen derivative of xylenol, known as 'dettol,' were much better. They left a protective film on the skin which lasted a matter of hours and thus should be of value in a prolonged labor. There was danger that with the introduction of sulfanilamide less trouble would be taken with the antiseptic ritual. Whatever the barriers, the fewest possible number of women should be delivered in a dangerous environment. Dr Colebrook favored the maternity hospital. In four years only one patient in 700 had hemolytic streptococcus infection while in domiciliary midwifery the proportion for this period had been one in 115.

#### The Medical Journals and the Royal Society of Medicine

An important part of the weekly medical journals consists of reports of the meetings of the medical societies. Of these much the greatest is the Royal Society of Medicine, which was formed by union of almost all the London societies and which in its twenty-three sections embodies all the specialties. It is a rule of this society that it holds the copyright of all its proceedings, which it publishes monthly, and that no paper can be published in a medical journal in extenso until after publication in the proceedings, and then only by permission of their editors. But the medical journals have been allowed to send reporters to the meetings and to publish abstracts of the papers and discussions. Any request from the chairman or from a speaker that something was confidential was always respected. The society has recently shown a tendency to secrecy which is resented by the medical press. Before a journal can report any meeting it must now ask permission, which is becoming more difficult to obtain. The *British Medical Journal* points out that a number of private medical clubs and associations exist for private discussion and that this should be extremely rare at the Royal Society of Medicine. The society exists to promote the science and art of medicine and has a duty to give as well as to receive information. Its contributions to the common stock of knowledge should be accessible to the whole profession not merely to the members of the society. Few discussions can be so delicate as to require privacy. The *Lancet* makes a similar protest and asks: Do those taking part in the debates want to speak to a restricted audience and to have their remarks recorded only weeks or months later and solely for the benefit of the members of the society? Now that the matter has been ventilated, the result will depend on whether the members of the society actually support the desire for secrecy which has been shown by the officials of the society.

#### The Medical Aspects of "National Service"

The need to organize this country so that no other will be tempted to attack it has been realized. The threat of air raids has rendered necessary the enrolling of the civil population capable of service in defense against them. A new term, "national service," on which the government has issued millions of handbooks, has been introduced to designate this work. In keeping with our traditions of liberty, it is on a purely voluntary basis. Men are being enrolled for air raid precautions, police duties and fire services and women for air raid precautions, ambulance driving and nursing. Physicians have been enrolled for war service by the British Medical Association. The handbook states that in view of the probable casualties in war there would be a great demand for nurses. Those who already have had nursing experience should reserve themselves for that duty and many now without experience should train for it. Women who undertake to do nursing or first aid work in war may offer to serve anywhere in the United Kingdom or abroad, if necessary, or they may make it clear that they would be unable to leave their home district. At the government's request, the College of Nursing has arranged to enroll trained and assistant nurses, whether members of the college or not, pending the formation of a representative committee that will take over the task. The evacuation of children from dangerous areas would make an unprecedented call on the services of women. Householders with spare accommodation in the relatively safe areas could do no more useful service than to assume the care and maintenance of such children. The handbook also gives particulars of national organizations by which men as well as women can be trained in first aid and ambulance work in war.

## Prevention of Diphtheria

At the Dec 20, 1938, meeting of the Académie de médecine de Paris a survey of the results obtained during the past fifteen years in the use of the specific toxoid vaccination against diphtheria was submitted by Prof Gaston Ramon. Over three million adults and children in France, two million children in Canada and, up to 1935, one million in New York have been given the Ramon diphtheria toxoid as a prophylactic. No proof has been offered to show that vaccination, when the properly prepared toxoid is used, is followed by any ill effects. Although the toxoid itself is conceded to be almost universally innocuous, there is no question that in certain persons who are intolerant of such a preparation one has observed more or less severe local and general reactions. According to the majority of those who have reported such reactions they are rarely seen in young children, the incidence increasing between the ages of 8 and 10 years. Local reactions, sufficiently marked to be worthy of mention, have been observed in from 2 to 5 per cent and more severe general reactions in from 5 to 10 per cent of those who have been vaccinated. Such a small incidence of reactions ought not to stop physicians from using the toxoid as a prophylactic. Serious reactions such as anaphylactic purpura or hematuria are extremely rare. Many reactions reported as due to the toxoid were found in reality to be the result of a lack of asepsis or to some associated systemic pathologic condition. Although it cannot be denied that reactions do occur from time to time after vaccination with the diphtheria toxoid, such reactions are far more often observed after other methods of active or passive immunization.

Ever since the first vaccinations with the diphtheria toxoid, investigation has shown that the toxoid is capable of conferring an immunity which is characterized by the presence in the blood of the specific antitoxin. During the early period it was found that from 5 to 10 per cent of the vaccinations were failures, the subjects being immunized either not at all or insufficiently. This explains why cases were reported of diphtheria occurring in those who had been vaccinated. During recent years marked progress has been made in obtaining a toxoid of higher antigen value, in repeating the vaccination and in the use of associated diphtheria and tetanus toxoids. These improvements in the technic of preparation and use of the toxoid have been followed by a greater activity, as shown by the fact that the Schick reaction becomes negative in 100 per cent of cases.

## RESULTS OF OBLIGATORY VACCINATION

Diphtheria tends to disappear in the French army because every soldier must be vaccinated. In city and country collectivities the use of the toxoid is more difficult to carry out, as a rule, yet in certain departments of France more than 50 per cent of the children have been vaccinated, with a striking fall in the mortality. Fifty years ago there were 1 500 deaths a year from diphtheria in Paris, whereas in 1937 there were only eighty-seven deaths, the mortality having dropped from eighty to less than three per hundred thousand inhabitants. The results obtained in foreign countries when the vaccination with the toxoid is correctly carried out are as favorable as those seen in France. Only when from 30 to 50 per cent of children in a given community are properly vaccinated can the effect of this prophylactic method against diphtheria be really evaluated. When the proportion of the

vaccinated rises to 70 or 80 per cent of the children in a community, the real merit of the method becomes very apparent. In order to be effective, vaccination ought to be made obligatory. This has been done in Hungary, Poland, Rumania and the city of Geneva, Switzerland. In France such a law was passed June 28, 1938, but has not yet been enforced, because of some opposition on the part of a few physicians and the public.

In the discussion the Paris pediatrician Dr Jules Renault said that vaccination with the diphtheria toxoid is successful in 96 or 98 per cent of cases. A child who has been vaccinated remains exposed to an infection for several weeks while the immunity is being established, hence he injects both the antitoxin and the serum when children are admitted to a contagious disease service in order to secure a rapid immunity. Then two other injections of the toxoid are given after an interval of fifteen days. This method was employed during the past six years with 6,000 children admitted on account of varicella, scarlatina, pertussis, mumps or measles. Only slight local reactions were noted in from 5 to 10 per cent of the children.

## Pneumonectomy for Cancer of Lung

In only about 10 per cent of the cases of pulmonary cancer observed clinically is the condition amenable to operative intervention, according to Dr Robert Monod, who reported two cases at the Dec 7, 1938, meeting of the Académie de chirurgie de Paris. Dr Monod stated that his first patient is the only one thus far operated on in France who has lived for two and one-half years. The diagnosis of a latent cancer which is primary in a peripheral part of the lung presents a more difficult problem than that of one which is primary in the bronchus, because with the latter type of cancer the cough, so often accompanied by expectoration, leads to an examination of the chest. A persistent pain in the upper part of the abdomen especially if recurrent, should always lead to an x-ray examination of the lower part of the chest. Dr Monod said that from the standpoint of technic a total pneumonectomy is not accompanied by a higher operative mortality than a lobectomy.

In the discussion, Dr Maurer who has had a large experience in pulmonary surgery, said that local anesthesia would suffice in the majority of cases. He preferred the anterior to the posterior method of approach because the ribs need not be removed and, with the aid of appropriate retractors, an ample exposure can be obtained. An additional advantage of the anterior route is that the patient lies on his back and can more easily utilize the other lung. Dr Maurer also advocates the use of an artificial pneumothorax as a preoperative procedure, because it prepares the lung for the ample exposure which is indispensable in such operations. He also preferred ligation of the individual structures of the pedicle to the use of a tourniquet. The results obtained in the treatment of pulmonary cancers, the majority of which are primarily bronchogenic, will continue to be very discouraging until earlier diagnoses are made.

In reply to Dr Maurer's advocacy of the anterior mode of approach, Dr Monod stated that it was applicable only in cases in which a preoperative diagnosis of a malignant condition had been made and was not so suitable in cases in which an exploration of the entire lung with respect to the size of the tumor was necessary. Dr Monod agreed with Dr Maurer as to the advantages of local anesthesia for the exposure of the tumor but said that general anesthesia was preferable for the endothoracic portion of the operation because it eliminated the serious reflexes so often encountered when local anesthesia is employed throughout the operation.

### Physicians with Large Families

The excess of deaths over births is causing anxiety hence every effort is being made to encourage the raising of large families. The government is granting a reduction in income tax and a monthly allowance to heads of families proportionate to the number of children. In addition Mr Cognacq owner of the largest department store in Paris, left money in trust, the interest of which is distributed annually to encourage an increase in the birth rate.

The medical profession is doing its share, as stated in the quarterly bulletin "Doctors and Their Families." There are sixty-one physicians with an average of ten children in each family. One physician heads the list with seventeen and another follows closely with sixteen children. Others worthy of mention are two with fifteen children, one with fourteen, six with thirteen, seven with twelve, eleven with eleven and thirty-one with ten children.

### Personal

The contributions of Dr Thierry de Martel to neurologic surgery are familiar to surgeons all over the world. The French government in recognition of this work has conferred on him the rank of Grand Officer in the Legion of Honor. Dr de Martel is head of the surgical department at the American Hospital of Paris.

### BELGIUM

(From Our Regular Correspondent)

Dec 23, 1938

### Collapse Therapy

Collapse therapy in the surgical treatment of tuberculosis is not based on immobilization of the lung and compression of the lesions but on relaxation of those elastic tissues which continually stretch the parenchyma, the procedure seeks to accomplish an elective remission of the lesions. In an address before the Societe medico-chirurgicale du Brabant, M Wybauw reviewed the various methods of collapse therapy.

Phrenicectomy is interesting but its results are the least predictable. If the phrenic nerve has received a preliminary alcoholization, it is easier to foresee the effect. Whereas intrapleural pneumolysis permits section of the adhesions under visible control, extrapleural pneumolysis frees the covered pulmonary apex from the two pleurae and introduces into the cavity thus formed either the pectoral muscles or paraffin. Wybauw has used paraffin, although he has found the procedure to have many disadvantages.

Extrapleural pneumothorax has been introduced with some notable successes but the postoperative happenings are rather complicated. The value of this procedure will be judged in the future.

Thoracoplasty is assuming an increasingly larger place in the surgical treatment of pulmonary tuberculosis and the technique is becoming more reliable. Its objective is remission of the lesions through progressive modeling. Brilliant results may follow the treatment of unilateral nonevolutive lesions by multiple stage thoracoplasties performed with a local anesthetic.

### A National Foundation for the Youth

In accordance with his traditional generosity and philanthropy, Baron Empain has made a further benefaction of 75 million francs for welfare activities among the youth. The foundation is called Pro Juventute. Its income will be used (1) to organize campaigns for improvement and development, physical, moral and mental of the youth, (2) for the award of prizes or other subsidies to encourage the youth to develop their mental and physical faculties and (3) to promote, protect or subsidize activities which have as their object the

improvement and development of the youth. The activities designated under 3 include (a) child welfare activities which would permit city children the advantage of outdoor life in the country and remove them from pernicious influences, (b) outdoor games and other activities which inculcate a sense of solidarity and fair play among adolescents and young adults and submit them to a rational, physical education based on medically supervised gymnastics, games and sports, including the activities of certain nonprofit athletic organizations which conform to the desired standards, and (c) supervised activities designed to improve the youthful intellect and especially to cultivate scientific or artistic bent among young men.

### A Center for Mental Prophylaxis

At the International Congress of Mental Hygiene, Dr Alexander of Brussels set forth the principles which should govern the organization of a foundation for mental prophylaxis. Such a work must be characterized by flexibility. The general activity must be first of all educational. Different sections would deal with particular phases of mental prophylaxis, for example prophylaxis of domestic difficulties through premarital consultations, child mental hygiene, care of mildly affected neuropaths, former hospital patients, former delinquents, former hoboes and drug addicts. The personnel, in addition to the specializing physicians, should include visiting nurses, social workers, a secretary, psychologists, sociologists and persons trained in vocational guidance. The center should maintain the closest collaboration with other medical specialties. The center would above all render service through its contacts with medical practitioners, medical centers, social centers, charitable institutions, judicial authorities and temperance societies. The center's staff physicians should as much as possible act as liaison officers between the center and the collaborating organizations.

### Diagnosis of Salpingitis and Appendicitis

Drs Schockaert, Rosman and Nolens have published in the *Journées médicales de Bruxelles* the results of their research on globular sedimentation as a factor in the differential diagnosis of acute salpingitis, appendicitis and extra-uterine pregnancy. The sedimentation rate is strongly accelerated in the vast majority of cases of acute salpingitis, and in cases of acute appendicitis the acceleration is much less marked, accordingly the test permits differential diagnosis of these two disorders in 95 per cent of cases.

In the pseudosalpingian forms of ectopic pregnancy the acceleration of the sedimentation rate is inconsiderable and in the majority of cases differential diagnosis between this condition and acute salpingitis is thus possible.

Let us assume the point of view of the surgeon or gynecologist called to attend a woman presenting a painful acute syndrome of the hypogastrium or of the right iliac fossa. Despite a good history and careful examination, doubt persists and no clinical sign sufficiently diagnostic of either salpingitis or appendicitis is present. The sedimentation test is easily done and the result is forthcoming within one hour. According to statistics studied by the authors the test permits solution of the problem and in 95 per cent of cases the indications of the sedimentation rate will be confirmed by clinical development or surgical intervention.

The authors believe that if the clinical picture creates serious doubt as between acute adnexitis and acute appendicitis, one may without undue timidity regard the sedimentation test as the basis of performance or postponement of a laparotomy. They recommend that if at the end of an hour the sedimentation rate has attained or exceeded 20 mm the woman should be put to bed and medical treatment of acute adnexitis begun, the chances are ninety five in a hundred that a useless opera-

tion can thus be avoided, and an operation performed at the acute stage of the disorder involves the risk of postoperative peritonitis

#### Dr Vervaeck Honored

A party was recently held at Forest prison in honor of Dr Louis Vervaeck, director general of the anthropologic-criminologic service, who, having reached the retirement age, is about to relinquish his post. He has been responsible for reforms in prison administration which have placed Belgium in the forefront of progress in this field.

### ITALY

(From Our Regular Correspondent)

Jan 14, 1939

#### Tuberculous Hemoptysis

Professors Sanguigno and Valentini, at a recent meeting of the Federazione per la lotta contro la tubercolosi, reported observations in about 3,000 cases of pulmonary tuberculosis. They concluded that alarming hemoptysis appears early in the development of pulmonary tuberculosis in about 10 per cent of the cases. The condition can be classified in three groups: (1) as the only symptom of early tuberculous infiltration of the lung, (2) as the first symptom of evolution of chronic pulmonary tuberculosis and (3) as a symptom appearing in association with other early symptoms of the disease. The second group is the most common. The frequency of alarming hemoptysis is the same for male and female patients. The symptom is frequent in exudative forms of recent development, especially phthisiogenic infiltration of the lung, and rare in primary, chronic and miliary forms. It originates as a rule in parenchymal ulceration of the lung or else, although rarely, in congestion of the organ. The age in 70 per cent of the patients is from 18 to 25, as the symptom is more frequent in young persons and in early maturity than at any other age. In some cases grave alterations of the lung take place before appearance of the first hemoptysis. A certain diagnosis of pulmonary tuberculosis can be made by clinical examination of patients after alarming hemoptysis in some but not in all cases. The sputum gave positive results for tubercle bacilli in 38 per cent of the cases seen by the speakers. In 50 per cent of their cases an early sanatorium treatment or collapse of the lung after hemoptysis induced improvement or clinical recovery.

#### Successor to Professor Alessandri

Prof Raffaele Paolucci was appointed head of the Clinica chirurgica of Rome to succeed Prof Roberto Alessandri, who retired on reaching the age limit. Professor Paolucci was born in Rome in 1892. He was lieutenant physician in the Italian navy during the World War. He was in the battle in which the Austrian warship *Viribus Unitis* was sunk. He was professor of specialized surgical pathology at the faculties of Modena and Bari and of clinical medicine at the universities of Parma and Bologna. He wrote articles on anaerobic bacteria in the appendix, pathogenesis of traumatic shock, relations between the thyroids and the sympathetic nervous system, innervation and motor functions of the intestine and surgery of the thorax in pulmonary tuberculosis and in nontuberculous suppuration of the lung.

#### Meeting of Surgical Society

The Societa medico chirurgica of Modena recently met with Professor Agazzotti as president. Professor Marogna spoke on ureteral calculosis. When the calculi are located at the pelvis or at the iliac or lumbar ureteral segments, the use of a retention catheter and injections of a hypophyseal preparation give satisfactory results. Surgery is resorted to as the

last resource. In some cases the calculi can be removed by means of pyelotomy performed after the passage of the calculi has been forced to the renal pelvis. Professor da Azzi said that he has observed that patients who are suffering from pneumonia suffer also from a deficiency of vitamin C in the blood and in the urine. Ascorbic acid, however, has no efficacious therapeutic action on pneumonia. Professor Dalla Volta reported three cases of frontoparietal cerebral tumors with symptoms similar to those of cerebral arteriosclerosis. The predominant symptoms were convulsions of the jacksonian type, which developed independently of the cerebral symptoms from twenty to twenty-five minutes after administration of an injection of 0.02 Gm of acetylcholine chloride. However, if the acetylcholine injection was immediately followed by an injection of 0.001 Gm of epinephrine the convulsions were inhibited. According to the speaker the acetylcholine injection caused dilatation of the intratumoral vessels with consequent increase of the size of the tumor and convulsions. The tumors found at necropsy were of the angiomatous type. Professor Mircoli followed the behavior of the electrocardiograms immediately before and after blood transfusion in sixteen cases of various diseases. In eleven cases the heart rhythm became slow and the altitude of the T wave increased after transfusion. There was no relation between the intensity of the electrocardiographic changes and the amount of blood which had been transfused. The speaker believes that the electrocardiographic changes are due to transient disorders of the nutritional metabolism of the myocardium after transfusion. Trabucchi did not accept Mircoli's interpretation. Isotonic liquids introduced into animals induce diminution of the altitude of the T wave. Blood transfusion improves the blood supply of the heart with consequent improvement of the physiologic contraction of the structure and slowing of the heart rhythm. From these factors the T wave in the electrocardiogram increases in altitude. Professor Mircoli and Ferromi measured by the congo red method the amount of transudate or exudate in the abdominal or pleural cavity in twenty-two patients. Stained specimens were withdrawn six, fifteen or thirty minutes after introduction of the stain and then the fluid was removed as completely as possible. The colorimetric calculations were done by the method used in determining the amount of circulating blood. The authors found that the amount of fluid withdrawn is slightly less than the amount calculated by the colorimetric method, however, the method is of value in calculating the amount of fluid in the abdominal and pleural cavities.

## Marriages

JOHN W. CROSKY, Philadelphia, to Mrs. Marie L. Bretschneider, Fort Washington, Pa., in Fort Washington, January 21.

WILLIAM H. CONWAY, Larchmont, N. Y., to Miss Helen M. McGraw, Johnstown, Pa., Nov. 24, 1938, in Johnstown.

SANFORD P. LEHMAN, Olympia, Wash., to Miss Constance Jones, Ann Arbor, Mich., in Seattle, Nov. 25, 1938.

WILLIAM FRANCIS HULSE to Miss Helen Frances Stark, both of Cleveland, in Detroit, January 28.

JOHN M. LEAHY, Tiffin, Ohio, to Miss Dorothy Slattery, Chicago, in Chicago, Oct. 10, 1938.

OLIVER S. ORMSBY to Miss Mary Horton, both of Chicago, in Louisville, Ky., February 4.

MARSHALL F. SHIELDS to Miss Eleanor Frances Collins, both of Chester, Pa., Sept. 14, 1938.

ROBERT T. ODON to Miss Mary S. Medearis, both of Fayetteville, Tenn., Sept. 29, 1938.

## Deaths

**Roy Gillian Werner** \* Akron, Ohio, Johns Hopkins University School of Medicine, Baltimore, 1915, past president of the Summit County Medical Society, served during the World War, on the staffs of the City and St Thomas hospitals, aged 55, died, Nov 12, 1938, of chronic ergotamine tartrate poisoning

**Damaso T Laine**, Bryn Mawr, Pa, University of Pennsylvania Department of Medicine, Philadelphia, 1886, fellow of the American College of Surgeons, veteran of the Spanish-American War, founded the Anglo American Hospital in Habana, Cuba aged 72, died, Nov 8, 1938, of cerebral hemorrhage

**Horace Colton Bliss**, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1897, member of the Ohio State Medical Association, aged 81, died, Dec 15, 1938, of arteriosclerosis and coronary thrombosis

**Anna M Braunwarth** \* Chicago, Woman's Medical College, Chicago, 1886 an Affiliate Fellow of the American Medical Association at one time medical superintendent of the Post Graduate Hospital, aged 81 was killed, Dec 19 1938 when struck by a bus

**Eber Leander Annis**, La Porte, Ind, Rush Medical College, Chicago, 1881, member of the Indiana State Medical Association, formerly secretary of the city and county board of health, and deputy coroner, aged 78, died, Dec 4, 1938 of coronary thrombosis

**Randall Burrows Hayes**, Jersey Shore, Pa, Jefferson Medical College of Philadelphia, 1900, member of the Medical Society of the State of Pennsylvania, on the staff of the Community Hospital, aged 60 died, Nov 24, 1938, of coronary occlusion

**William Francis Herron** \* Pittsburgh, University of Pittsburgh School of Medicine 1925 instructor in medicine at his alma mater on the staff of St Francis Hospital aged 37, died, Nov 9, 1938 of cerebral thrombosis and cerebral arteriosclerosis

**Gordon Bostwick Maurer** \* Margaretville, N Y, Yale University School of Medicine New Haven, Conn 1923 medical superintendent of the Margaretville Hospital, aged 39, died, Nov 12, 1938, of an accidental gunshot wound received while hunting

**Boyd Bell Snodgrass** \* Rochester, Pa, Marion-Sims College of Medicine St Louis, 1898, secretary of the Beaver County Medical Society on the staff of the Rochester General Hospital, aged 68, died Nov 8 1938, of coronary thrombosis

**Henry Harrison Smith** \* Johnsonburg, Pa Jefferson Medical College of Philadelphia, 1887 past president of the Elk County Medical Society, past president of the school board, aged 76, died Nov 4, 1938 of cerebral hemorrhage

**Samuel E Jordan**, Highland Home, Ala Tulane University of Louisiana School of Medicine New Orleans, 1905, member of the Medical Association of the State of Alabama, aged 57 died, Nov 27 1938, of carcinoma

**Jesse N Clore**, Madison, Va, Medical College of Virginia, Richmond, 1895, member of the Medical Society of Virginia, formerly secretary of the county board of health, aged 69, died, Dec 1, 1938 of coronary thrombosis

**James Harvey Bradfield**, Monterey, Calif, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1901 aged 62, died, Nov 5, 1938, of lobar pneumonia and coronary sclerosis

**James Thomas Strickland**, Roanoke, Va, Jefferson Medical College of Philadelphia, 1882 member of the Medical Society of Virginia, aged 81, died, Nov 25 1938, of myocarditis and adenocarcinoma of the prostate.

**Ralph Vernon Moss** \* Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1923, on the courtesy medical staff of the Frankford Hospital, aged 41 died, Nov 10, 1938 of heart disease.

**Wilhelmina G Bickelmann** \* Brooklyn, New York Medical College and Flower Hospital New York, 1919, on the associate staff of the Prospect Heights Hospital, aged 44 died Nov 10 1938, of heart disease

**William Alexander Stevens**, Okanogan Wash Jefferson Medical College of Philadelphia 1886, member of the Medical Society of the State of Pennsylvania, aged 74, died Nov 10, 1938 of a ruptured appendix

**John Adolph Fischer**, Philadelphia Hahnemann Medical College and Hospital of Philadelphia, 1895, aged 66, died, Nov 15 1938 in the Temple University Hospital of carcinoma of the colon and peritonitis

**Alfred Henry Catterall**, Hawley, Pa Medico-Chirurgical College of Philadelphia, 1896 aged 63, died Nov 1, 1938, in the Moses Taylor Hospital, Scranton, of carcinoma of the pancreas with metastasis

**Bruce H Snodgrass**, Beaver Falls, Pa, Marion-Sims College of Medicine, St Louis, 1896, member of the Medical Society of the State of Pennsylvania, aged 65, died, Nov 1, 1938, of coronary thrombosis

**Bernard Sandfeld**, Miami, Fla, Medical College of Ohio, Cincinnati, 1887, aged 73, died, Nov 15, 1938, in the James M Jackson Memorial Hospital of cholelithiasis, cholangitis and aplastic anemia

**Lewis Gravely Pedigo**, Salem, Va, University of the City of New York Medical Department, 1881, member of the Medical Society of Virginia, aged 80, died, Nov 21, 1938, of pernicious anemia

**James V Munger**, Portland N Y, University of Buffalo School of Medicine, 1891, aged 83 died, Nov 20 1938, in Buffalo of hypostatic pneumonia and carcinoma of the larynx

**Thomas J Allison**, Nocona, Texas, Louisville (Ky) Medical College, 1890, member of the State Medical Association of Texas aged 87, died, Dec 16, 1938 of coronary occlusion

## Bureau of Investigation

### WILLIAM HOWARD HAY AND HIS "CORN" DIETETICS

#### Hokum Reaches a New High in the Poconos and a New Low on the Far-Flung Plains of Illinois

Frequently William Howard Hay has been mentioned in *THE JOURNAL*. His original sanatorium, called the "Hav Rest Cure," was located at Youngsville, Pa. In *THE JOURNAL*, Feb 25, 1933, attention was called to his subsequent activities at the East Aurora Sun and Diet Sanatorium at East Aurora N Y, and later at Pocono Hav-ven Mount Pocono, Pa. Evidence in the files indicates that in 1934 he moved to Briarcliff Manor, N Y. Subsequently, however, he returned to Mount Pocono, and now he operates the institution there under the name Pocono Haven.

The Hay System is just some simple and not always scientific advice about diet. No one disagrees with the tenet that none of us should overeat and that every one should eat a nourishing diet of natural foods. Hay goes on, however, to advocate the avoidance of mixtures of proteins and starches at the same meal and is apparently so wrapped up in this tenet that many of his menus are of inadequate caloric content. This theory of the incompatibility of proteins and starches has been broadcast far and wide but apparently on the wrong wavelengths, for as yet Mother Nature has heard nothing of it. Green pers still contain about 7 per cent protein and at least, on the average, an equal amount of starch, potatoes 18 per cent protein and 14 per cent carbohydrate, and the human system still converts 58 per cent of protein into carbohydrate. It is interesting to consider some of the foods which Hay himself advocates. Whole wheat flour is chiefly starch but contains 13.8 per cent of protein; wheat germ contains about equal quantities of protein and starch. Eventually people will realize that most foods contain some protein, some carbohydrate and some fat. Meantime, however, Hay apparently continues to prosper in promoting folderol.

As part of his propaganda Hay tries to discredit established medical science. His ridiculous diatribe entitled "Who Are the Quacks?" was released by the American Medical Liberty League. In this little document Hay developed the thesis that the quacks are not the food faddists, the cultists, the "drugless healers," the chiropractors or the naturopaths but, instead, the members of the regular medical profession.

Spas, scientifically conducted, are deservedly popular with many people. The gullible portion of the public, unable to differentiate between the spas in which ethical medicine is practiced and those in which faddists convene, attends institutions such as that operated by Hay and falls easy prey to the misinformation he perpetrates.

Among Hay's publications is one called "The Hay System News." According to its cover it is "published by the Hay Alumni Association," "to extend the teachings of William Howard Hay, M.D." In a current issue Dr Hay answers medical questions. In reply to an inquirer who states "A member of our family suffers with extremely cold hands and feet during the winter time. Can you tell us the cause of this trouble?" Hay replies:

Cold hands and feet may be objectively cold yet subjectively warm. By this I mean that they may feel cold to others yet not be noticeably so to the owner. The condition of objective coldness may accompany high stages of health while objective warmth may accompany high states of toxemia as I have very often noted. It is not always wise to attach too much importance to this symptom if it is a symptom.

But it is far wiser, Dr Hay, than attaching too little importance to such a symptom "if it is a symptom," as it may be indicative of serious vascular disorders.

The Alumni Association which publishes "The Hay System News" apparently has branches, including one at Champaign-Urbana, Ill., where, according to the December 1938 issue of "The Hay System News," there was a meeting on November 10 of the Hay Health Guild. The meeting began with a banquet—if Hay food can be so designated—and was attended by approximately 500 members. The program included songs by Bruce Foote of the Music Faculty of the University of Illinois and

"a very interesting and helpful address on 'Compatibility'" by Dr William Howard Hay. The final sentence of this report reads: "There is no more enthusiastic group of followers of the Hay System, anywhere, than in these 'Twin Cities'."

These twin cities include within their limits the University of Illinois and the homes, fraternity houses and dormitories which house the students and faculty of this great midwestern university. One might expect that, in a community which is composed approximately one fourth of various members of the university faculty and the student body, such faddism would never be popular. The fact remains, however, that at least one restaurant is cashing in by following the edicts of Hay and serving the foods and food combinations suggested by him. Obviously, such activities are a matter of interest to the home economics and biochemistry departments of the university. Probably both are surprised and chagrined that such activities should ensue in these university cities.

There is not the slightest scientific evidence to back up the Hay theory concerning incompatibility of foods. Dr Martin A. Rehfuess of Philadelphia tested such diets on 200 normal men. He also tried them on a great many sick people. Some were fed mashed potatoes and chopped beef together as foods which represented concentrated starches and proteins. Dr Rehfuess discovered that it took only three minutes longer for sick people to digest the beef and potatoes together than it did to digest the beef itself.

These facts are all well known to the medical profession. They have been discussed in numerous books and publications. Two books which have described bluntly the activities of Hay are "Your Diet and Your Health" by Dr Morris Fishbein and "Diet and Die" by Carl Malmberg. The *Reader's Digest* for May 1933 published an article exposing the fallaciousness of these principles of Hay's.

At the time of the founding of the East Aurora institution by one Oliver Cabana Jr., who a number of years ago put out a preparation called "Kem-O-Zone" and described as "The Aristocrat of Antiseptics" it was claimed by Cabana that he had selected Hay as medical adviser to his institution because he was "nationally known for the past decade as an authority on dietetics." Just exactly who designated Hay as an authority on dietetics is not clear. He is not listed in "American Men of Science" and, as far as this Bureau knows, is not a member of any scientific organization in the field of dietetics or nutrition. Not satisfied with his activities in the "twilight zone" of dietetics, he has issued certain statements concerning well established scientific remedies. He claims, for instance, in his book "Health via Food" that "evidence of the efficiency of serum immunization is still entirely lacking, for we have no way of knowing whether one supposedly immunized against any form of disease would ever take such disease, even under extreme exposure." This total disregard for voluminous scientific evidence would be entirely inexcusable, even if it were a statement by a layman and not a graduate in medicine.

Before Hay commenced his activities in this field, he claimed to have been active in the practice of surgery, and yet his book "Health via Food" includes the following paragraph under the chapter entitled "Everyone His Own Physician":

Until the writer sees at least one case of appendicitis die naturally whether this be a simple catarrhal and uncomplicated case or a perforated case with abdominal abscess he is sure to be excused for not taking this condition as seriously as it is painted by the surgeon who knows nothing but the operative treatment of this really simple condition.

This fallacious piece of philosophy is entirely misleading, since it is obvious that those who die with perforated appendices do not die "naturally," whether in "quotes" or otherwise.

Starting with the treatment of asthma, Hay has referred in glowing terms to his treatment of pernicious anemia and, according to a letter from a former patient, published in this Bureau's column in *THE JOURNAL* for Jan 4, 1936, attempts to control diabetes without employing insulin.

Hay appears to be convinced that much that is wrong with any one can be attributable to his failure to follow the principles laid down in the Hay diets. Extensive scientific evidence in both research and clinical medicines refutes completely and entirely his fantastic theories.

The edition of "The Hay System News" previously mentioned contains an article by William H. Hay II. No title, however, is published after his name. Presumably he is neither

a Doctor of Medicine nor a Doctor of Philosophy in biochemistry or nutrition. His writings on the subject are based, apparently, only on his own cogitations. Under the heading 'Disease,' he says

'One fact should be brought home in vivid fashion to the youth of our nation. Disease does not immediately manifest itself in the form of tuberculosis, cancer, arthritis and the like. Disease is present when the body is not 100% efficient in every way. It is evidenced by obesity, unaccountable fatigue, catarrh, and numerous other innocent appearing signs. These conditions are not generally recognized as disease for the failure of the family doctor to pigeonhole them under the head of some definite ailment automatically crosses them off our list of worries.'

Latest reports indicate, however,\* that the "family doctor" is still the first-line battler against disease. At any rate he is not attempting to confuse the public about disease as is Hay II.

From high in the Poconos comes the call to follow Hay. Most people know enough to recognize it for what it is and to consider the call so much static. In Champaign and Urbana the news has yet to be adequately disseminated. No doubt leaders in the university realize that they have an obligation here to their local community.

## Correspondence

### ERYTHEMA NODOSUM

*To the Editor*—The recent editorial on erythema nodosum (THE JOURNAL, January 14, p. 147) should receive wide attention from the medical profession. There are at least three reasons why this subject has an importance beyond the theoretical implications. First those who regard the condition as essentially tuberculous—Wallgren for example—have intimated, as a logical outcome of their observations that patients afflicted with erythema nodosum may be possible sources of the spread of tubercle bacilli to others, if this is true, then important epidemiologic considerations arise in the care and isolation of these patients. Second, assuming that there is a rheumatic variety of erythema nodosum then the possibility of subsequent serious cardiac disease must inevitably loom large in such cases. Third, if either of these views is correct, then patients with erythema nodosum could not be granted insurance rates on the same basis as ordinary persons.

I am a member of a small minority that still regards erythema nodosum as a disease *in generis*. This letter is intended as a plea that nothing be assumed as established until proved definitely.

I. The epidemiologic observations made by Brandon and his co-workers are interesting but the chief thesis of their communication was not substantiated for the following reasons:

(a) It is stated that there was an 'open' case of tuberculosis in the school (a boy aged 17) but it appears that this diagnosis was based alone on a remarkable history of this disease in the patient's immediate family and on the observation in the boy of a positive tuberculin reaction and of a roentgenogram showing 'thickened linear markings and some slight shadowing in the apex of the left lung'. It seems hazardous to speak of 'open' tuberculosis without offering proof in the form of tubercle bacilli in the sputum or, at least, other confirmatory data. If such evidence had been present it should have been so stated. The term 'open' tuberculosis as used in this report requires clarification before its significance can be assessed properly.

(b) The patient who was believed to be suffering from 'open' tuberculosis lived in cottage J, which was later found to have sheltered but one patient with erythema nodosum whereas the other cottages (N and S particularly) had eight and four patients with this disease respectively. Moreover, the isolated patient with erythema nodosum in cottage J had also been in close contact with the first patient to have this disease in the epidemic (cottage N) having carried meals to him. In other words there were many more cases of erythema nodosum in places apparently less exposed to the influence of the boy with open tuberculosis. In order to explain this discrepancy it was assumed

that there had been other means of intimate contact, such as the swimming pool. It seems fair to conclude on the basis of these data, that the source of this epidemic was not definitely established and that there remain too many lacunae awaiting clarification.

2. Regarding the data on rheumatic erythema nodosum it is true that Wallgren described three cases in his report, but of these three he was willing to accept only one as truly rheumatic. It is my belief that an isolated example in which the evidence of relationship was suggestive but not conclusive, compared with an experience of about 800 cases of erythema nodosum, as stated by Wallgren, can hardly be construed as substantiating the rheumatic nature of this condition, at least the factor of coincidence must surely be taken into account. There is an enormous gap between Mackenzie's view that all instances of the disease are of rheumatic origin and Wallgren's apparent demonstration of a single rheumatic case observed among 800 cases of erythema nodosum.

My interest in erythema nodosum is based on a correlation of the dermatologic and the internal medical aspects of a large number of instances of this disease, including two small endemics, thus far I have attempted only an analysis of the relation of this condition to rheumatic fever (*Ann Int Med* 10:1686 [May] 1937). One cannot but be impressed by the imposing edifice of observations on the tuberculous nature of erythema nodosum, but it appears that there are many gaps in our knowledge; moreover, there is much contradictory evidence on fundamental points, all of which will be discussed in a critique under preparation. It is my belief that erythema nodosum as observed in this country differs in no remarkable way from the disease seen in other parts of the world, including the Scandinavian countries, the clinical picture, the high incidence of positive tuberculin reactions (including the vesicular response), the frequent occurrence of hilar shadows, the occasional finding of a negative tuberculin reaction, the recurrences and the like are identical to those reported from other countries. Moreover, the evidence strongly indicates that this condition in adults is essentially similar to that observed in children. The theory that erythema nodosum is a nonspecific cutaneous reaction to a variety of causes is based, in my opinion, on a mass of doubtful data.

HARRY KEIL, M.D., New York

### HIPPOCRATIC LETTERS ON THE INDEPENDENCE OF THE PROFESSION OF MEDICINE

*To the Editor*—Apropos of the present controversies on state medicine and the hiring of physicians on the same basis as workmen, it seems timely to bring to mind the following little episode. The 'Council and Citizens of Abdera' wrote to Hippocrates to come to their city and treat the ailing Democretus, their most illustrious citizen, promising him 'all the glory, learning and gold' their city could afford. The fact that a whole city should be so greatly concerned over the health of one citizen impressed Hippocrates, and he agreed to come. That the Abderites should think, however, that they could hire the services of a physician for a stipulated sum of money the same as of any other artisan, he considered an insult. So he even asked his 'guest friend' Philopomen for hospitality, during his stay in Abdera, not wanting to trouble a city already so disturbed' with his private physical needs and to the Abderites he remarked: 'For my coming neither nature nor God can contract me for money nor may you citizens of Abdera, do me violence (i.e. insult me with such a suggestion), but let the works of a free art remain likewise free. Those who hiring themselves out for salary, force the sciences into servitude, rob them of their ancient freedom and reduce them to utter slavery. Consequently, they would be as though the disease is serious, or deny it is trivial not coming when promising or

coming without being asked. Indeed the life of men has become miserable, because this unbearable covetousness, like a hurricane, has permeated it throughout." This reminds one of some of the present criticisms of the panel system.

I am, of course, aware of the very serious objections as to the authenticity of these so-called hippocratic letters. However, the time and the spirit is hippocratic and it should matter but little who actually penned them. The excerpt is offered for the consideration of both sides, and a familiarity with the spirit it displays might prove profitable to both physicians and laymen.

SAVAS NITTIS, M D, Ann Arbor, Mich

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### DEATH FROM INSULIN SHOCK OR OTHER CAUSE

*To the Editor*—Kindly criticize the following treatment. A woman aged 52 while eating supper suddenly fell into a deep snoring slumber from which she couldn't be roused. Her daughter gave the following history: Mother was told she was diabetic and she had been on insulin and a special diet for about six months. We covered about 300 miles today and twice during the afternoon mother complained of not feeling well and she took a little nap in the bus. She always took her protamine zinc insulin in the morning before breakfast [quantity unknown]. Out side of the diabetes she apparently was in good health. The patient unfortunately was not seen until after having been in coma for over an hour. Her face was pale, the eyeballs were soft, there was a slight suggestion of acetone on the breath, the skin was sweaty, respirations were labored and apneic in character, the pulse was of good quality (about 80), the blood pressure was 130 systolic, 80 diastolic. There were no heart murmurs, the patient was relaxed and the superficial reflexes were sluggish but no abnormal ones were present. The patient was rushed to the hospital where the bladder was immediately catheterized and a blood specimen taken. Ten per cent dextrose in physiologic solution of sodium chloride was started. Examination of the urine revealed specific gravity 1.010, acetone negative and sugar negative. Following this report stimulants were started such as epinephrine, caffeine and strychnine. The 10 per cent dextrose was stopped and 50 cc of 50 per cent dextrose solution was given slowly. The patient did not respond at all but seemed to sink deeper, her respirations coming about once every two minutes. Just as the blood sugar report came back 52 the patient's pulse became irregular and she died. A urea nitrogen test later revealed a level of 38. 1. The condition resembled insulin shock or hypoglycemia; was proper treatment instituted? 2. What is the terminal picture in hypoglycemia? 3. Could protamine zinc insulin have exerted a peak influence early in the evening to have produced the shock picture? (No severe exercise was taken during the day to deplete the sugar.) 4. How long can one remain in shock before treatment is hopeless? Is it possible to be in diabetic coma (acidosis) with a low blood sugar, urine sugar and acetone free? If kidneys stop excreting waste products?

M D, Oregon

*ANSWER*—Treatment of this case under the circumstances appears sensible, but the diagnosis of the condition remains in doubt. First, it is rare for a patient while eating a meal to develop insulin shock, but it does occur. Second, an argument against insulin shock is the rapidity with which a blood pressure of 130/80 and a pulse of good quality changed and the patient died. Third, a blood sugar of 52 mg is not as low as one ordinarily encounters during insulin shock which has persisted in the stage of unconsciousness over a considerable period. Fourth, the insulin shock came on rapidly and treatment was instituted within an hour, and with such prompt treatment a prompt recovery would be expected. Fifth, extreme pallor, soft eyeballs and a labored respiration, apneic in character, are not characteristic of insulin shock. A necropsy might well have shown cerebral or coronary sclerosis with accompanying lesions.

The terminal picture in hypoglycemia is not well known. In three recent cases supposed to be typical of death in hypoglycemia, coronary occlusion was found in two and a pulmonary embolism subsequent to a fracture in the third. It is perfectly possible for the symptoms to come on suddenly and thus for perspiration and tremor to be absent. The respiration is usually normal, blood pressure certainly normal at first.

Protamine zinc insulin could have exerted a peak influence early in the evening, but one would have expected a lower blood

sugar to produce such an advanced stage of shock. The fact that the shock came on during the meal does not militate against the possibility of insulin shock, because the food might not have been absorbed. Repeatedly dextrose or other forms of carbohydrate are given in the early stages of shock and do not bring about prompt improvement and later this is explained, because the stomach empties itself of all that was administered. In such instances people generally get well of themselves or with the help of repeated feedings or dextrose given intravenously or subcutaneously.

If a patient is unconscious in insulin shock for more than eight hours there is grave danger. No instance is recalled from experience or in the literature in which recovery has occurred after unconsciousness of twelve hours.

It does not appear possible for a patient to be in diabetic coma caused by acidosis with a low blood sugar and to have the urine free from sugar and acetone. If the kidneys were blocked, acetone and diacetic acid might disappear from the urine but would be present in the blood.

### DROWNING AND RESUSCITATION

*To the Editor*—Can you tell me how long a person has been under water and then resuscitated regardless of whether or not death occurred a short time later from complications? The reason I am asking is that I have seen in several books statements to the effect that persons who have been immersed as long as thirty minutes have been resuscitated. Don't give up! Persons who have been under the water as long as thirty minutes have been resuscitated by this simple method (Daiton F E Swimming Scientifically Taught New York Funk & Wagnalls Company 1931 p 246). Persons have been known to have been restored to life after having been under water for a half hour (Sullivan F J Science of Swimming New York American Sports Publishing Company 1932 p 91). There are cases on record of people having been revived after being under water for half an hour and unconscious several hours (Hindley L de B Swimming for Women New York American Sports Publishing Company 1931 p 90).

R D STREETOR M D Moberly, Mo

*ANSWER*—All laboratory tests have agreed in showing that after about four minutes of complete deprivation of oxygen in the brain—as by occlusion of the arteries—irremediable damage has occurred. If instead the trachea is clamped, the oxygen in the air in the lungs postpones this result perhaps a minute or two. Absolutely sudden and complete submersion for six or seven minutes may therefore be expected to render resuscitation impossible. But considering the way in which drownings actually occur, with the possibility that the victim has drawn a partial breath before his traditional "going down the third time," ten or twelve minutes may elapse during the "drowning" and therefore resuscitation may still be attainable. As for such longer periods as half an hour, it may be remembered that no one actually times them, and that in view of many successful resuscitations of persons apparently dead it is well to encourage prolonged efforts.

### DIAGNOSIS OF SYPHILIS

*To the Editor*—A man aged 47 was originally infected with syphilis in 1910. He states that there was no doubt about the original infection since he had gone out on furlough with three other persons and all were infected. He was treated with arsphenamine from 1910 to 1912 and he had malaria from 1912 to 1914 on several occasions while in the tropics. He is married and has two healthy grown children and a grandson. Routine and provocative Wassermann tests at intervals have been negative. There has been no treatment since 1912. Up to September 1938 the spinal fluid had not been examined. In September he suffered a nose bleed. The examining physician stated that the cause was either hypertension or syphilis and concluded that it was the latter as the blood pressure was 130/90. The patient came to my attention about September 15. Examinations revealed no physical or neurologic abnormalities. The nasal mucous membrane was normal. The blood pressure was 130/90. X ray examination of the heart showed nothing suggestive of syphilis. The blood serum reaction was negative. The spinal fluid was normal as to Wassermann and Kahn and colloidal gold tests. The patient is somewhat worried and no doubt a diagnosis made twenty-eight years ago has irretrievably affected his life. Was syphilis present originally? Had the malarial infection of 1912 to 1914 an adverse influence on the course of the supposed syphilitic infection? Does the negative serum reaction rule out a syphilitic infection? How should the case be handled?

M D Michigan

*ANSWER*—The fact that the patient now shows no clinical or serologic evidence of syphilis does not mean that he did not acquire syphilis in 1910. It is known that practically one third of the patients who acquire syphilis will control the disease spontaneously, and this patient may belong in this group. As he manifests no signs of the disease at this time, there is no way in which the original diagnosis made in 1910 can be confirmed or disproved. It is true no doubt, that the psychological effect of this knowledge on the patient has been great, but the only way this can be offset is to reassure him that,

although one cannot say whether or not he had the disease in 1910, the evidence now indicates that the syphilis has apparently been cured. It is likewise impossible to say just what effect the malarial infection of 1912 to 1914 had on the course of the disease, because many patients with a serious type of syphilis are seen who have a malarial infection after they acquired the syphilis. It would seem advisable to reassure the patient to the utmost and to urge him not to take treatment but, if he wishes, to come in once a year for a recheck simply to assure himself that he need have no worry regarding the disease.

#### PRIMARY JEJUNAL ULCER

*To the Editor*—I recently had occasion to examine a white man aged 42 who showed all the signs and symptoms of an acute perforated ulcer. On operation a primary jejunal ulcer was found to have perforated. No other ulcers were found elsewhere in the gastrointestinal tract and there had been no previous abdominal surgery done except an appendectomy seven years before. In going back over the literature I am unable to find mention of a case of perforation of a primary jejunal ulcer in which the jejunal ulcer is of the peptic type and no previous abdominal surgery had been done. If you know of such a case I should appreciate the references.

M D Pennsylvania

*ANSWER*—Primary jejunal ulcer must be an extreme rarity, as many large necropsy series fail to record a single case. W W Ebeling (Primary Jejunal Ulcer *Ann Surg* 97 857 [June] 1933) of Philadelphia, in a comprehensive article states that only forty-seven cases including one of his own had been reported in the literature between 1827 and 1932. Only seven of these ulcers had been operated on in the absence of perforation. While tuberculous ulceration and syphilis produce changes in the jejunum, the pathologic change of a primary jejunal ulcer is different in that it is similar to that of chronic peptic ulcer as found in the duodenum. Most of these ulcers occur in the upper part of the jejunum and are situated opposite the mesenteric border. The symptomatology is not unlike that of duodenal ulcer, although the pain may be located in the upper left quadrant, especially in the occasional case in which upper jejunal obstruction has occurred. X-ray examination may be of some aid in diagnosis. The diagnosis, however, has not been made in most cases until after perforation has occurred. Perforation has followed trauma in one or two instances. Resection of the ulcer is naturally the treatment of choice.

#### TREATMENT OF HEMOPTYSIS IN PULMONARY TUBERCULOSIS

*To the Editor*—Should small doses of morphine sulfate (from one eighth to one fourth grain (0.008 to 0.016 Gm)) be used in hemoptysis in cases of pulmonary tuberculosis? Is the value of this drug in quieting the patient and controlling the cough overshadowed by the danger of producing spread of disease by permitting blood and sputum to collect in the bronchi? Is there risk of producing pneumonia by placing an icebag on the patient's chest to keep him quiet? Would you outline a routine to be followed in treating a tuberculous patient with hemoptysis?

M D Connecticut

*ANSWER*—Morphine in ordinary doses does not stop cough completely, therefore there is not much increase in danger from the blood collecting in the bronchi. The greatest danger in this respect comes from slow internal bleeding. As a rule the doses specified can be used with safety.

An ice bag placed over the precordium has a tendency to slow the heart rate. It does not tend to cause pneumonia. Absolute quiet of the patient gives the best chance of stopping bleeding. This includes also the assurance given the patient by the physician himself.

The treatment of pulmonary hemorrhage may be divided into prophylactic and active. The former depends on the early diagnosis of ulcerations and prompt collapse therapy or other forms of treatment supplemented always with the sine qua non of tuberculosis therapy—rest.

Active treatment in actual bleeding differs depending on the amount of hemorrhage. In ordinary bleeding blood spitting, oozing or seeping hemorrhages the patient should have absolute rest, small doses of morphine or barbiturates. Phenobarbital is good and is preferred by some to morphine. Coagulants such as calcium gluconate or lactate have been recommended but their actual efficacy has not been demonstrated. They inspire the patient however so that the fear of death or great hemorrhage is removed somewhat. Chipped ice by mouth, ice cream for food and an ice pack to the chest are useful and may be used profitably.

As soon as any danger of bronchopneumonia has passed, collapse therapy should be done.

In massive hemorrhage the patient should have collapse of the bleeding lung as soon as possible until bleeding stops and be put to bed in a horizontal position with the head elevated enough to keep him from strangling in the sputum or blood that may come up. Then all the other measures mentioned before may be used, as necessity dictates.

#### ILL EFFECTS OF PROLONGED STANDING ON WOMEN

*To the Editor*—As medical inspector of our department of labor I happened to inspect a canning industry in which women in its trimming department have been working in the standing position all the time. Please explain to me what ill effects this working in the standing position for at least eight hours a day will be likely to bring to these women.

JOSE SANTILLAN MD Manila P I

*ANSWER*—Most disorders attributed to prolonged standing are associated with the lower extremities, such as varicosities with eczema or ulcers, flat foot, and knock knee. Bone and joint changes have been reported in young women and children in whom the osseous system is imperfectly developed especially when unnatural posture or repetitive movements are added considerations. Also in the case of women greater incidence of dysmenorrhea with or without associated uterine displacement is stated to occur. Similar functional disturbances may take place in the case of abdominal organs in persons with viscerotonic tendencies. Bulletin 136 of the Women's Bureau of the U S Department of Labor contains a section on seating equipment for women workers and the regulations which have been adopted in certain jurisdictions. Various commentators have pointed out that due care must be taken that the facilities provided are not as injurious as standing itself, that seats or benches are readily accessible and adjustable to the working place, with backs, arm and foot rests if needed and the number of seats supplied in proper relation to the number of employees.

#### PAINFUL AND STIFF FINGERS AND TOES AFTER CEREBRAL HEMORRHAGE

*To the Editor*—A white man aged 62 suffered a cerebral hemorrhage last January resulting in a paralysis of the left side. He gradually improved until now he can walk again and do light work. His Wassermann reaction is negative, blood count normal and blood pressure around 170 systolic, 90 diastolic. His reflexes are all hyperactive. He also has several carious teeth. His chief complaint is pain and tenderness in the ends of his fingers and toes; another complaint is a progressive stiffness of the joints of his hands. I gave him six injections, one every three days of sodium iodide 1 Gm without any relief. I should like to know the cause of the pains and tenderness in his fingers and toes and the treatment.

M D Ill

*ANSWER*—It is assumed that the pain and tenderness in the fingers and toes is bilateral. If this is the case it is extremely unlikely that the cerebral hemorrhage is directly responsible. Occasionally a hyperesthesia accompanies cerebral hemorrhage but only on the affected side.

There are a number of conditions that might produce the complaint mentioned. Circulatory disturbances must be ruled out. Buerger's disease (thrombo angustis obliterans) is a possibility. This disorder is not symmetrical in its distribution and rarely affects the upper extremity to the same extent that it affects the lower. Raynaud's syndrome is symmetrical in its distribution but it is not continuous and is associated with blanching of the skin. Weir Mitchell's disease (erythromelalgia) produces discomfort of this sort. This condition is aggravated by a dependent position and by heat or is relieved by elevation of the part and by cold. Scleroderma may be painful even before thickening of the skin occurs. In subacute bacterial endocarditis Osler's nodes, small painful elevations on the finger tips and toe tips occur as a result of embolism of the end arteries. This appears unlikely in this case. The pain of arteriosclerosis is rarely symmetrical and is made worse by exercise.

Nerve disorders must be considered. An avitaminosis may produce a peripheral neuritis. Certain drugs, notably arsenic produce a like effect.

The progressive stiffness of the hands in patients of this age is usually the result of an osteoarthritis. This condition often progresses rapidly when customary exercise is abandoned for any reason.

Correct therapeutic procedures will depend on a more accurate diagnosis. The effect of heat and cold should be tried both for therapeutic and for diagnostic reasons. The effect of vaso dilators should be investigated. For this purpose one of the compounds of thiochrome or theophylline may be used.

### ABSENT TEETH AND DELAYED DENTITION IN BABY

*To the Editor*—A white baby an only child aged 16 months has a complete absence of teeth. The baby held its head up at 2 months sat up at 6 months walked at 11 months and says several two syllable words now. Physical examination is normal except for a tendency to dry hair dry skin and absence of all teeth. There is no evidence of rickets. The baby has been spoiled and no regular dietary regimen has been followed because of unwillingness of the parents to cooperate. The Wassermann reaction is negative and there is no family history of syphilis or delayed dentition. X-ray examination of the skull shows unerupted teeth present. The film was not a good one. X-ray examination of the wrist bones shows only two carpal bones present. According to the roentgenologist this shows the development of a 6 months infant. Oct. 15, 1938 I started the baby on one-half grain (0.03 Gm.) of thyroid extract (Armour's) orally daily. I know that infants who have manifestations of thyroid deficiency often have delayed dentition. However this child's mental development has been normal. Are there any other causes of delayed calcification of the carpal bones other than thyroid deficiency? How long should I keep giving thyroid extract if the child shows no physical improvement but continues to do well mentally?  
M D Virginia

*ANSWER*—It is doubtful whether the infant discussed is suffering from a lack of thyroid secretion. Thyroid deficiency in infancy is manifested by slow growth in height, thick, dry, wrinkled skin, pasty complexion, dull expression, thick tongue, protuberant abdomen and short, thick hands. There is a delayed closure of the fontanel.

It is true that delayed dentition and tardy ossification of the carpal centers accompany thyroid deficiency. However, physical and mental development are retarded also.

In certain nutritional disorders, especially rickets, there is a delay in the calcification of the carpal bones. It should be pointed out, however, that there may be considerable individual variation in the time at which the carpal bones become calcified. The infant mentioned in the query may well be within the range of normal.

If there is no response to the treatment within one or two months, the administration of the thyroid gland extract should be discontinued.

### OPHTHALMOGRAPH AND METRONOSCOPE

*To the Editor*—As president of the board of education I am interested in knowing whether or not there is any scientific basis for the use of metronoscopes and ophthalmographs in the public school system for the purpose of detecting visual defects and their correction. Worlds of literature emanate from educational institutes where reading laboratories are maintained which set forth the great value of these instruments. I have been unable to find any medical literature on the subject and would appreciate any information you may be able to give me.

E J CUMMINS M D El Paso Texas

*ANSWER*—No strictly medical literature on the metronoscope or ophthalmograph has been found. The ophthalmograph has been used for photographing the movements of the eyes in reading and it does give a record of ocular imbalance in reading and of faulty reading habits. A certain amount of skill and experience is required to obtain good records with it. Unless such records are obtained the use of the metronoscope does not seem scientific, since it should be used only for children whose reading rhythm is proved to be defective by such a record. Probably no one knows what proportion of cases showing reading disability is due to poor reading rhythm which could be detected and might be corrected by the two instruments. The problem is rather one for educators than for ophthalmologists.

### INTRAVAGINAL TAMPONS AND OBSTRUCTION OF MENSTRUAL FLOW

*To the Editor*—I have had a few cases of severe pain in the right lower quadrant which followed a normal menstrual period during which time the patient had used intravaginal tampons to absorb the menses. Two cases of severe pain showed signs of peritoneal irritation. Rigidity, tenderness below McBurney's point and rebound tenderness were present in both cases. There was marked tenderness in the right fornix. However there was no vomiting, nausea, fever or increased white count. All symptoms subsided in forty-eight hours and did not recur when the use of intravaginal tampons were forbidden. I believe that the entire syndrome was due to back pressure by a snug tampon. I should like to know your opinion.  
M D New York

*ANSWER*—It is entirely possible that the symptoms enumerated may have been due to the escape of blood from the uterus through one or both fallopian tubes into the pelvic cavity. Good evidence in favor of this is the fact that the attacks failed to appear when the intravaginal tampons were not used. Most likely the tampons were inserted high enough into the vagina to obstruct the external os. Ordinarily if there is no obstruction

at the external os the blood which escapes from the uterus remains in the vagina until the tampon is removed. If the external os is not blocked, a back flow of blood through the tubes can occur only if a large amount of blood is dammed back in the vagina. Of course in some cases blood may escape into the peritoneal cavity without any obstruction, an occurrence which in the opinion of Sampson and others is responsible for most cases of external endometriosis.

### PERMANENT WAVE AND CONSTITUTIONAL DISEASE

*To the Editor*—Every now and then a patient states that hairdressers claim that there must be some constitutional disease present as they are unable to get a permanent curl in the customer's hair. Thus far I have never seen literature that would enable me to solve this problem. Has anything been written regarding this matter?

W L CASLER M D Marquette, Mich

*ANSWER*—So called permanent waves are produced by wetting the hair with an alkaline solution to soften it and then heating it while on the curlers long enough to produce steam. This fixes the curl for a longer time than any other method yet discovered. It works well with most hair, but even the most expert hairdressers have difficulty with some kinds of white, overbleached, stringy or dyed hair.

"Constitutional disease" is a common excuse used by hairdressers whose failure to accomplish a good curl is not uncommonly due to poor technique or poor preparations. A test curl made on one lock of hair preliminary to the operation will sometimes spare both operator and subject the distress of failure. It is not an uncommon experience for the woman who has been told that some mysterious constitutional disease or condition prevents her hair from taking the curl to get a perfect result by employing another more expert hairdresser.

### TRAUMA AND REGIONAL ILEITIS

*To the Editor*—Will you discuss the possible relationship between so called terminal ileitis and trauma? References to the ileitis syndrome would be appreciated.  
M D New York

*ANSWER*—Although most of the many articles which are now appearing on so called terminal or regional ileitis make no mention of trauma as an etiologic factor, Mock (*Infective Granulomata, Surg Gynec & Obst* 52:672 [March] 1931) mentions trauma as one of the factors in production of infective granulomas. He refers more particularly, however, to inflammations following the presence of foreign material such as mass ligation with silk, sponges left in the intra-abdominal cavity, and similar conditions. While all authors regard the etiology of regional ileitis as obscure, it is generally agreed that the process is of some unknown bacterial or virus origin. An excellent bibliography including over 100 articles is to be found at the end of a paper by Maxwell Lick on "Regional Ileitis" (*Surg Gynec & Obst* 66:340 [April] 1938).

### ONSET AND DURATION OF SYMPTOMS FROM FOOD ALLERGY

*To the Editor*—In a case of vasomotor rhinitis in which certain foods are the proved cause (such as potato and wheat) approximately how long might the interval be between eating the food and the onset of the attack? Approximately how long might symptoms continue to appear or be present from a single attack producing amount of the allergen?

M D Washington D C

*ANSWER*—Foods such as potatoes and wheat which cause vasomotor rhinitis usually act within a period of time varying from one-half hour to three or four hours. In extremely sensitive persons symptoms may occur almost immediately after ingestion, on the other hand, in less sensitive persons the symptoms may not occur until twenty-four hours after eating. Certainly twenty-four hours would be the late limit in almost every case. The duration of symptoms will vary from a few minutes to perhaps as long as three or four days or even longer in occasional instances.

### REDUCED FECUNDITY IN RADIO WORKERS

*To the Editor*—A 33 year old radio engineer whose work keeps him in close contact with radio transformers complains of sterility. His sperm count is found diminished with a large preponderance of dead sperm. He states that those in this work are of a reduced fecundity which factor is common knowledge to them. Is this true? Can you refer me to articles on this subject?  
M D Alabama

*ANSWER*—Although the X-rays will at times cause sterility, there is no evidence that workers in radio machines are ever affected in this fashion. There are no cases on record and no articles on the subject.

## Book Notices

**Human Pathology A Textbook** By Howard T. Karsner M.D. Professor of Pathology Western Reserve University Cleveland Ohio. With an introduction by Simon Flexner M.D. Fifth edition. Cloth. Price \$10. Pp. 1013 with 461 illustrations. Philadelphia & London J. B. Lippincott Company 1938.

The object of a textbook of any scientific subject is to provide for the initiate a logical and understandable guide which will enable him (1) to acquire the fundamental principles, (2) to orient the different yet related phases of the subject material, (3) to incorporate all such information into the sum total of a fruitful knowledge and (4) to instill the spirit of response to the challenge in the search for new and as yet unknown truths. Such a concept of purpose is especially applicable to the comprehensive subject of pathology.

Textbooks in pathology are written from the point of view of the generalizations of disease as applied to the various systems and organs (general pathology), from the point of view of the specific considerations of the morbid anatomy of the various organs and systems (organ or system pathology), or with a combination of these two considerations. The latter is the arrangement in this textbook.

The average writer of the modern textbook in pathology is undoubtedly motivated by a desire to present the subject clearly, logically and comprehensively, yet sufficiently concise to enable the struggling student sufficient time to meet the exacting demands of other instructors in a rapidly advancing "curricular" curriculum conspiracy. To meet this situation certain textbooks abound in attractive, often dogmatic, brevity. The author levels off his competency to a stratum of knowledge too incomplete to be beneficial to either the student, author or subject. In his preface Dr. Karsner admirably points out that "the doctrine of purpose should not be permitted to smooth too easily the paths of learning, especially if it entails a critical analysis of cause and effect."

There are three preeminent qualities in Karsner's textbook: (1) pertinent outlines of each subject, (2) vivid and scholarly discussions and (3) excellent and often inclusive bibliographies following the exposition of each major dissertation. To the teacher it affords a stimulus to a better pedagogy, for the student it provides a *modus operandi* for the epitomizing, orienting and retaining of the maze of facts and theories of the continuously growing science of disease. One cannot emphasize too much the helpful assistance that such a textbook in pathology gives to the student not only while he is taking the course but later when he begins to apply his knowledge of pathology to the recognition of disease in his patients and the alleviation of human suffering. Such practical application is made possible on the basis of a better understanding of the altered anatomy and physiology induced by the various etiologic agents of disease.

The book is amply illustrated if supported by the usual demonstrations available in the lecture room and laboratory. More complete illustrations would undoubtedly enhance its value in keeping alive for the physician the impressions of disease he acquired as a student. Realizing that illustrations are costly and that students are usually poor, the writer is nevertheless impressed with the soundness of the economic principle of paying well for a complete portrayal in words and illustration afforded by a good textbook of pathology or any other science, especially when such books may be made to serve as the personal and "cherished guides" of scientific knowledge throughout the life of the student and physician.

Karsner's *Human Pathology* continues to maintain an enviable position among the excellent American textbooks on this subject.

**The Practice of Medicine** By Jonathan Campbell Meakins M.D. LL.D. Professor of Medicine and Director of the Department of Medicine, McGill University, Montreal, Quebec. Second edition. Cloth. Price \$12.50. Pp. 1413 with 521 illustrations. St. Louis: C. V. Mosby Company 1938.

The first edition of this work appeared in 1936. In his preface the author emphasizes the necessity for individualization of patients, particularly in the control of infectious diseases, indicating that every patient is an *experimental problem* to the scientific physician. The feature of the Meakins work is the extensive illustration. Whereas some may criticize the medical student

will find this feature most commendable. It may be said of the illustrations that they have been most carefully chosen and all of them actually illustrate.

In the preparation of the new edition there have been extensive revisions of many of the sections in which new information has been developed. The opening chapters are for the average student a fine philosophic approach to the practice of medicine. This volume, which is in outline form, is ideal for the medical student.

The section on vitamins unfortunately is altogether inadequate. Thus it is stated that there are now recognized five vitamins, which hardly gives an adequate picture of the situation. The consideration of migraine occupies some thirty lines. This is inadequate, since it fails to reveal many of the etiologic factors commonly discussed in other works. The treatment offered is apparently wholly empirical. Obviously, this great work suffers from the same difficulties of other works of similar scope, namely the unevenness of the treatment of various subjects. However, on the whole the volume compares quite favorably with other works in this field.

If there is any single criticism which should be made against this volume, it is of carelessness in editing, which might easily be controlled by more meticulous attention. For example:

This Utopia has not yet arrived but in the meantime we must do the best we may.

The generally accepted facies of mitral disease are characterized by a deep reddish color.

Pneumothorax is not the result of trauma; it is most frequently due to pulmonary tuberculosis and spontaneous pneumothorax due to such may occur without any obvious parenchymatous pulmonary lesion.

It has already been described how the internal carotid and the vertebral arteries form the circle of Willis.

In treatment, the author refers frequently to pharmaceutical preparations that are little used in the United States but which have sale in Canada.

**Abortive Poliomyelitis.** Rein abortive und nicht pareitische Formen der Heine Medin'schen Krankheit. Von Dr. med. Otto Gsell, Chefarzt der medizinischen Abteilung am Kantonsspital St. Gallen (Schweiz). Boards. Price 6.70 marks. Pp. 94 with 13 illustrations. Leipzig: Georg Thieme 1938.

This short monograph on abortive poliomyelitis is a valuable contribution to the subject. Although the author presents a brief review, his remarks are quite pertinent. He begins with a short historical outline of the subject and discusses in a systematic manner the epidemiology, the clinical appearances in the various types of abortive poliomyelitis, the pathologic changes, the differential diagnosis, prognosis and prophylaxis, and the therapy of this disease. It is of interest to note the many references to American contributions to this subject. The author states that the first report on the abortive type of poliomyelitis was made in 1894 by Caverly, who discussed the epidemic in the Otter Creek Valley in Vermont. Subsequent contributions were made by writers from Norway, Sweden, Germany and Switzerland. In the epidemiology of this disease the author discusses local epidemics in various countries, particularly Germany and Switzerland. Later the larger epidemics are reviewed and toward the end of this chapter a detailed discussion of epidemics of abortive poliomyelitis that occurred in the Jungfrau district in Switzerland. In this section the larger epidemics in Denmark and California in 1934 and in Sweden in 1936 are discussed in some detail. In the discussion of experimental and immunobiologic observations in abortive poliomyelitis the author refers to the work of Flexner and his associates among others. The clinical forms of this test are classified by the author as: (a) The nonparalytic form of poliomyelitis, which includes the poliomyelitic form of serous meningitis, the neuritic form and the encephalitis form. In this group the author emphasizes particularly the "spine" sign, which is pain over the region of the vertebrae and stiffness of the neck, the Lasague sign, which is similar to the Brudzinski, headache, characteristic facies of poliomyelitis, obstipation, fever and lastly spinal fluid changes, which may vary from an increase in neutrophils in the spinal fluid the first few days of the disease and later present a predominance of mononuclear cells. The spinal fluid is not very characteristic in the abortive type of poliomyelitis. (b) The pure abortive type of poliomyelitis. The author discusses the similarity to various other diseases, such as bacterial endocarditis, typhus and meningismus. As to the pathol-

ogy of this condition, there is grossly a cloudy swelling of the heart, liver and kidneys, and the blood vessels of the brain are engorged. Under differential diagnosis the author discusses such conditions as meningococcic meningitis, tuberculous meningitis, the meningitis associated in croupous pneumonia, Weil's disease, acute syphilitic meningitis, and meningitis due to virus diseases. Although the book is brief, it is highly recommended to all physicians.

**Medical Information for Social Workers** Edited by William Matthew Champion A.B. M.D. With the assistance of the contributors from the Faculty of Western Reserve University School of Medicine Cleveland Ohio. Cloth Price \$4. Pp 520 with 26 illustrations. Baltimore: William Wood & Company 1938.

Nine physicians from the faculty of the Western Reserve University School of Medicine have aided the author in preparing an outline of medical information for the use of social workers. The book is not expected to teach social workers how to recognize diseases, how to estimate the physical capacity of the patient to work or how to apply remedies. It is hoped merely by its use to aid the social worker in serving more efficiently as a liaison officer between doctor and patient. Since statistics seem to show that the majority of failure to secure adequate medical care seems to arise in our present times not so much from poverty as from ignorance, the social worker has a vital place in bringing the patient into contact with the available medical care. The social worker may be called on to make the decision for the patient as to when the home shall be left for the hospital or the sanatorium. The chapters on the selection of a physician and on the history of medicine are followed by individual chapters giving fundamental facts regarding various forms of disease. The book concludes with outlines for examinations and with an excellent bibliographic supplement.

**Histological Technique for Normal Tissues Morbid Changes and the Identification of Parasites** By H. V. Carleton M.A. B.Sc. D.Phil. University Lecturer in Histology Oxford and E. H. Leach M.A. B.Sc. Demonstrator in Histology Oxford. Chapters VI and VII in collaboration with Frederic Haynes M.A. Second edition. Cloth Price \$7.25. Pp 383 with 18 illustrations. London New York & Toronto: Oxford University Press 1938.

"The worker in biology or medicine must be an Aphrodite, quick to transform the cold ivory of Pygmalion's technical result into the glow of the living cell." So enlightened an attitude leads the reader to expect much and he is not disappointed. The point of view and the consistent effort to rationalize the histologic procedures is a unique character of the book. It is written primarily for students and technicians and does not aim to be encyclopedic. The authors and their associates have had personal experience with all the methods described and as a result many details are included which often spell the difference between success and failure. The fundamental differences between histologic and cytologic procedure are stressed but there is not much intimation of the gulf that lies between a microtome knife that will cut satisfactory 10 micron sections and one that will give good 4 micron sections. This is especially true of celloidin work. One would hardly suspect from the rather summary treatment of this procedure that many histologists insist it is vastly superior to all others, even for serial sections. The work is divided into five parts. Parts I and II deal with general principles and type methods. The general discussion of the cell and the chapter on the theory of staining are perforce brief and simple but unnecessarily dogmatic in view of the many controversial issues involved. Part III describes the principles and practice of dark field study, certain microchemical and injection methods and the staining of fresh tissue. Attention may be called to an error on page 191. R. R. Bensley was the first to show that the "mitochondria" of Benda are specifically stained supravitaly by Janus green. Part IV gives special histologic and cytologic methods for various cells, organs and tissues and comprises the bulk of the book. Numerous changes have been made in this edition. Important new methods that have been added are the Feulgen nuclear reaction, which replaces all staining methods for chromatin, the brilliant differential staining methods of Masson, the galloxyanin technic for Nissl substance, and the newer diovan and double embedding procedures. Part V details various special methods used in pathology, bacteriology and parasitology. Chiefly by economizing on ems, considerable new material has been added and the total number of pages has been reduced as compared to the first edition.

**Medicine in Modern Society** By David Riesman. Cloth Price \$2.50. Pp 226. Princeton New Jersey: Princeton University Press, London: Oxford University Press 1938.

The author has collected a number of essays in a volume published under a grant from the Louis Clark Vanuxem Foundation. The book includes a brief account of medical progress with philosophic reflections. Especially interesting are the chapters on medical education, those on the neuroses and the concluding chapters, in which the author expresses his concept of the future of medicine. If one wished to be hypercritical, one could easily point out the discrepancies in thought between the chapters on medical education, on medicine as a career and on medical ethics with the conclusions presented in the chapters on the social outlook in medicine. Yet one does not wish the author to be scientific in his leisurely contemplation of medical sociology and medical economics. He approaches the field as an amateur and it is interesting to have him present his own point of view, which does not seem to be very distinct or concrete. If there is any one point which Dr. Riesman's essays reveal, it is the fact that his personality is of the compassionate, reflective, humanitarian type that makes good physicians but sometimes exceedingly inefficient businessmen, organizers or politicians.

**Manual of Veterinary Bacteriology** By Raymond A. Kelsner D.V.M. A.M. Ph.D. Lieut. Colonel Veterinary Corps United States Army. Third edition. Cloth Price \$6. Pp 640 with 93 illustrations. Baltimore: Williams & Wilkins Company 1938.

The first edition was published in 1927 and contained 525 pages and eighty-seven illustrations, a second edition appeared in 1933 and contained 552 pages and ninety-three illustrations. The author states in his preface that the need for a third edition at this time is due to the place the work has found in the libraries and laboratories of those interested in the bacteriology of diseases of the lower animals and especially to its adoption by numerous colleges and universities as a textbook for use in the teaching of veterinary bacteriology. Much new material is introduced in the various sections, and the chapters and subject material have the same orderly and systematic arrangement as in previous editions. The classification of bacteria as developed by Bergey has been continued. Chapters on protozoa and hematology are again included. Kelsner's Manual of Veterinary Bacteriology is the foremost work in the field of veterinary bacteriology and no doubt will maintain its prestige as an authoritative and comprehensive reference work of value. It should also continue its popularity as a textbook among veterinary students and others interested in animal diseases. The book should likewise prove a valuable help to medical men and general laboratory investigators, as many animal diseases also affect man. In the latter group may be mentioned actinomycosis, anthrax, botulism, avian and bovine tuberculosis, tetanus, rabies, tularemia, psittacosis of parrots, various pathogenic fungi, influenza, brucella infections causing undulant fever in man, and equine encephalomyelitis. The subject of equine encephalomyelitis is of special significance now that this disease has been definitely linked with human encephalitis. The chapters on bacterial variation and filtrable viruses are entirely new and contain much of the new knowledge that has come to light in the five years since the publication of the previous edition.

**Refraction of the Eye** By Alfred Cowan M.D. Associate Professor of Ophthalmology Graduate School of Medicine University of Pennsylvania Philadelphia. Cloth Price \$4.75. Pp 319 with 175 illustrations including 3 colored plates. Philadelphia: Lea & Febiger 1938.

The first thirteen chapters, 167 pages, are devoted to physiologic optics, given in somewhat less detail than the author's book on Ophthalmic Optics published by the F. A. Davis Company in 1927. Chapter 14 is on the lens changes in accommodation, method of determining the accommodative power of the eye, presbyopia and its symptoms and cycloplegics and their uses. He states on pages 181-182 that atropine used in the conjunctival sac reaches its maximum cycloplegic effect in two hours. If this were true why should it be used for "a day or two before refractions"? He also states on page 183 that homatropine hydrobromide is "an efficient and adequate cycloplegic." Two sentences later he says "It is unsatisfactory in children." He further states on page 184 of cycloplegics that "they are unnecessary in older presbyopes." With this dogmatic state-

ment we must take issue. On page 185 he states of ametropia that "the tendency is usually toward a too great growth of the eyeball—hypermetropia toward emmetropia, emmetropia toward myopia and myopia increasing." This is an old belief based on studies with incomplete cycloplegia. Recent investigations showed that hyperopia increases and myopia may remain stationary. On page 199 the author states that "axial hypermetropia never reaches to such high degrees as myopia, even 5 D is uncommon and 8 to 9 D is rare." With complete cycloplegia, from 8 to 9 diopters is common and even 10 to 12 diopters is not rare. On page 200, "Hypermetropia is said to develop sometimes in diabetes." This is merely a latent hyperopia become manifest. In chapter 17 are given a brief description of instruments and lenses used in refraction, the theory of retinoscopy and the various methods for objective and subjective refraction. Chapter 18 is devoted to routine procedure in the conduct of the examination and writing the prescription for glasses as well as remarks on bifocal lenses. The final chapter deals with contact glasses and telescopic spectacles. The book is well illustrated and will be useful to beginners in refraction but would be vastly more useful if greater space were used to cite case histories and examples of the various types of refractive errors and what to prescribe for each.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Hospitals Liability for Negligence of Physician Whose Services Are Provided by the Hospital**—The defendant was a charitable institution maintaining a school and a hospital. In 1928, the plaintiff underwent a tonsillectomy at the defendant's free clinic, the operation being performed by a physician assigned to the case by the defendant. Alleging that the hospital was negligent because, without knowledge of the physician's fitness or ability to perform the operation, and without making a proper and adequate examination to determine his competency, it permitted him to operate and to subject the plaintiff to careless and unprofessional treatment, the plaintiff sued the hospital. The action was commenced in 1931, more than two and less than three years after the operation. The trial court dismissed the complaint on the ground that the acts which were the foundation of the action constituted malpractice and that therefore the two year statute of limitation applicable to malpractice actions barred the action. The plaintiff appealed to the supreme court of New York, appellate division, second department.

In the opinion of the appellate court, the act which formed the basis of the action was not the malpractice of the physician but the defendant's negligence in selecting him when it knew or should have known that he was not qualified to perform the operation. That was the charge made against the hospital both by the allegations of the complaint and by the terms of the stipulation entered into between the parties. The defendant may be held liable only for its negligence in selecting the physician, the court pointed out, not for the latter's negligence or malpractice in performing the operation. In other words, a charitable institution which makes a physician available for the patient's use is not liable for malpractice. It is in no sense an employer or principal.

If the allegations of the complaint be established, the court said, the negligence of the hospital in selecting the physician and the malpractice of the physician in performing the operation were concurrent causes in producing a single wrong or injury to the plaintiff, for which she may recover against the hospital. The fact that the plaintiff suffered a single wrong or injury to her person, while it may authorize only one recovery, does not necessarily give rise to a single cause of action. It may give rise to several causes of action. Here the origin and nature of the wrong alleged gave rise to two causes of action—one against the physician for malpractice and one against the hospital for

its negligence in selecting him. The former is governed by the two-year statute of limitation and the latter by the three year statute.

The order of the trial court in dismissing the complaint was therefore reversed and the case remitted for further proceedings.—*Roczekamp v New York Post Graduate Medical School and Hospital (N Y)*, 4 N Y S (2d) 751

**Medical Practice Acts Proof that Person Treated Has a Disease Unnecessary**—The appellant was convicted of practicing medicine without a license and appealed to the court of appeals of Alabama.

The appellant had no license to practice medicine. A witness for the state testified that in April 1937 she was sick and under the care of a physician. The appellant came to her home and told the witness that she was just throwing away money by continuing treatment under the physician and that he, the appellant, could take the case. He gave her medicine and wrote several prescriptions for her, which the witness' husband had filled at a drugstore. The appellant was paid a fee of \$25 for his services which apparently extended over a period of a week. All this testimony was corroborated by the patient's husband. The appellant categorically denied the evidence presented by the state.

The medical practice act of Alabama declares it to be unlawful for any person to treat or offer to treat "diseases of human beings" without having obtained a certificate of qualification from the state board of medical examiners. On appeal, the principal contention urged by the appellant was that the state had failed to prove that the person alleged to have been treated was suffering from a disease, citing the case of *Frazier v State*, 19 Ala App 322, 97 So 251. But, said the court, the case cited was no authority for the appellant's contention, for in it the court said:

We are not however of the opinion that in a prosecution under this statute [the medical practice act] the state must either allege or prove that the person treated in fact had a disease. The statute reads:

Any person who treats or offers to treat diseases of human beings in this state by any system of treatment whatsoever etc. Acts 1915 p 661. Whether the person receiving the treatment or offered to be treated has a disease or not does not relieve one treating or offering to treat, from criminality. The fact that one claiming to be able to treat diseases of the human body offers to treat a person for a disease which that person did not have would be the worst kind of 'quackery' and was one of the things aimed at by the statute. Again if it should be held that the person offered to be treated must in fact be affected by the disease offered to be treated each case would present a case for the highest and most technical investigation involving diagnoses and other questions of pathology and scientific medicine. Such certainly, was never in the minds of the Legislature.

Furthermore, the person alleged to have been treated testified that she was sick when the appellant came to her home and the terms sick, sickness or disease, the court pointed out, are used interchangeably, and are of practically the same import.

The court could find no reversible error in the record and therefore affirmed the judgment of conviction.—*McAllister v State (Ala)* 181 So 511

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Theelin, Fever and Sulfanilamide for Gonorrheal Vaginitis**—During the last three years Burpee and his co-workers have had under their observation 112 cases of gonorrheal vaginitis in young girls. In the majority of the girls the infection was probably acquired from an adult in their homes. Complications were common. Apparent cures following the intramuscular injection of theelin in oil as the only form of treatment were obtained in forty-one of forty-seven cases. In five of these there were recurrences. Five patients treated with theelin and 1 per cent silver nitrate jelly were cured and did not have recurrences. Apparent cures following fever as the only method of treatment were obtained in eight of nineteen cases. There were no recurrences. In six of the seven patients treated with fever during theelin therapy apparent cures could be attributed to the fever. The fever was produced by the intravenous injection of typhoid vaccine and in five cases by the Kettering hypertherm. Apparent cures followed the oral administration of sulfanilamide as the only method of treatment in eleven of twenty-two cases. One patient had a recurrence. Two patients were cured by

the combined treatment of fever and sulfanilamide. There was a recurrence in one. All cures due to sulfanilamide were obtained in less than two weeks. Increase of the dose, prolongation of the treatment and combination with fever therapy did not improve the results. Fever therapy and sulfanilamide are recommended for further investigation.

**Development of Mongolism**—Although the available data are not sufficient to allow one to make a definite and final conclusion as to the exact time of the operation of the factor or factors which lead to the production of mongolism, Southwick believes that it can be stated, on the data that he found in fifty-eight cases of mongolism in dizygotic twins, that the causes of mongolism must reside in some factor or factors that cannot at any stage of development act directly on more than one ovum, zygote or embryo. Since at all stages of the development two or more ova, zygotes or embryos may occur in exactly the same external environment, one can conclude that the condition can develop only from within the gametes and so must be either chromosomal or cytoplasmic. The extreme infrequency with which two or more persons with the condition appear in one family makes it justifiable to conclude that mongolism is not produced by hereditary factors. The factors therefore are not considered to act at the time of the formation of the gametic chromosomes. It is suggested that the production of mongolism may be definitely associated with substances liberated from the ovum and from the spermatozoon and that mongolism may be the result of fertilization in which one or the other gamete was in an aged condition transitional to the nonfunctional or inactive state. That the spermatozoa may thus be effective is shown by the abnormal sex ratio that occurs among those with mongolism, and that the ovum may be similarly effective is shown by the definite relation between the age of the mother and the frequency of production of mongolism. This study is based on the records of 259 persons with mongolism.

**Effect of Tuberculosis on Serologic Reactions for Syphilis**—Parran and Emerson discuss the general field of tuberculosis with regard to the possibility that this toxemia adversely influences the specificity of carefully conducted serologic tests for syphilis. The study was participated in by five serologists. From 458 supposedly nonsyphilitic tuberculous donors of blood obtained from nine sanatoriums, the serums of eight were found to be positive to many laboratory tests. A minute review of the histories of four patients revealed evidence which supported the probable presence of syphilitic infection. Three of the remainder were not available for reexamination, while follow-up of the remaining one failed to reveal a history or clinical evidence indicative of syphilis. As the blood from this patient was strongly positive to all tests on both original and follow-up examination and as the eight instances of unrecognized and unsuspected syphilitic infections in the 458 cases are within the normal expectancy, it seems

justifiable to omit the entire group of eight cases from the final tabulation. Communications from some of the serologists called attention to the atypical nature of many of these adverse results. The authors' conclusion is that, since with the present serologic tests for syphilis both typical and atypical false-doubtful and false-positive results are found in serums from tuberculous donors, it is evident that tuberculous toxemia may contribute a confusing factor to the serologic study of syphilis. It should not, however, present a major problem in the clinical interpretation of results obtained with carefully conducted sero-diagnostic procedures.

**Pulmonary Tuberculosis in Young Adults**—Soper and Amberson find that tuberculous infection in young adults in this country and abroad is by no means universal. Roughly speaking, in this country 50 per cent of the white population less than 20 years of age does not react to tuberculin. In some sections, as the Middle West, the percentage of positive reactors is considerably lower. The medical student and the student nurse are more intimately exposed to tuberculous infection during their training than are those in other professions and occupations. This is attested by the disproportionate increase of positive reactions to tuberculin during their training. Infection in them may produce a primary type of lesion in the nonallergic individual or the superinfection type in the allergic. Recognizable lesions appear to occur more frequently in the nonallergic than in the allergic. Allergy may be said to be associated with a definite protective influence within certain limits. The severity of infection of nurses and medical students appears to be decreasing owing to the greater application of methods to prevent exposure, improved diagnosis of the acquired disease in its earliest stage and better living standards. A greater and more widespread emphasis on prevention of infection and on early diagnosis, particularly by tuberculin and the x-rays, should reduce the hazard in students to that of the general population or even lower. Its accomplishment is a direct obligation of the institutions concerned.

\*Role of Inflammatory Bronchial Stenosis in the Etiology of Bronchiectasis P. H. Holinger Chicago—p. 1070

**Deficiency Reaction in the Nose**—Hargett believes that atrophic rhinitis is a deficiency of the mucous glands of the nasal epithelium, either because there is an inadequate number of them or because the function of those present, if their number is normal, is abnormal, or a combination of the two. When the stratum corneum is removed from the skin, the moist layers beneath refuse to submit to drying and exude lymph and fibrin, which coagulates and dries, forming a protective coating, so that the cells below continue their function in a moist state. The author points out that the same reaction occurs in the mucous membrane of the nose. The microorganisms normally inhabiting the nose invade these scabs and produce the typical ozena. As this condition persists over a long period, a secondary defensive measure begins on the part of the mucous membrane to form a stratum corneum for itself. This process begins at the junction of the skin and mucous membrane at the opening of the nares and gradually extends

backward. This, the author believes, explains why atrophic rhinitis is most severe and is most often seen in the posterior half of the nasal cavity and why the condition never extends into the mouth and seldom into the pharynx, with the large and copious salivary glands to keep these parts moist. The author knows of nothing that will help the condition after cornification has taken place. But before cornification takes place treatment should resolve itself into trying to lighten the load of the glands present, to restore them to normal function and perhaps to stimulate their proliferation. If one side of the nose is closed through a deviation, the amount of air going through the other side is equalized, and thus the work of the glands, by a straightening of the septum. Operations which reduce the amount of air going through the nose by moving the lateral walls inward ease the burden of the glands, and some cures are effected. Paranasal sinusitis preceding the atrophic rhinitis coincides with the theory of deficiency. As with the other organs of the body, it seemed reasonable that the condition of the glands might be improved by periods of rest. This was accomplished by placing cotton plugs in one or both nostrils. It was found convenient to have the patient place these plugs in the nose at bedtime and remove them the next morning, giving the membrane eight or more hours of rest. Patients soon become accustomed to the mouth breathing necessitated and make no complaints. If the plugs are used while there is active sinus infection the patient immediately feels worse, and this is an indication to begin simultaneous treatment of the sinus, always being conservative at first. As soon as the sinusitis begins to improve, the plug treatment may be begun, and at this stage the patient will usually remark on the improvement. If the adenoids are infected they should be removed, but it is well to give preoperative douches daily for about a week.

**Inflammatory Bronchial Stenosis and Bronchiectasis**—The specific reaction which Holinger discusses is the inflammatory bronchial stenosis which produces complete or partial bronchial obstruction leading eventually to atelectasis and then to bronchiectasis. He correlates this sequence of bronchial inflammation, bronchial obstruction, atelectasis and, eventually, bronchiectasis as it has been observed in a series of children. He compares a previously reported series of bronchiectatic children who were observed from the onset of the pulmonary disease and followed to fully developed bronchiectasis with similar cases observed early and treated bronchoscopically in which the process was aborted, thus reemphasizing the effect of breaking this sequence by prompt recognition and clearing of the original lesion. Inflammatory bronchial stenosis was found to be responsible for the production of the original pulmonary lesion, atelectasis. "Atelectasis precedes and plays a prominent and most constant role in the development of a common form of bronchiectasis of the lower lobes" (Anspach, 1934). Persistent pulmonary changes simulating pneumonia are frequently due to atelectasis. If the lung does not clear spontaneously, early and frequent bronchoscopic drainage of the involved bronchi will prevent permanent dilatation and destruction of the bronchial walls, which follow if the atelectasis is left untreated.

Bacteriologic Study of Eating and Drinking Utensils A. L. MacNabb F. White and O. W. Owen Toronto—p. 591

**Typhoid Carriers in Nova Scotia**—MacRitchie states that in Nova Scotia the average annual death rate from typhoid for the ten years previous to 1932 was 17.9 per hundred thousand of population. For the five years from 1932 to 1936 the average rate was 4.2, the lowest of any province in Canada and slightly less than that of British Columbia, a province which has always had a low rate. From April 1936 to April 1938 the department of public health of Nova Scotia has been able to detect and place under a degree of control eight residual carriers, making a total of twenty now listed. The histories

of three of these carriers are reported. The three lived at different points within a radius of ten miles and during the preceding years 75 per cent of the cases reported in the province were from this section. A cholecystectomy was performed in all three cases.

**Limp Due to Coxalgia.**—Calve and his associates believe that the limp of coxalgia is a limp of escape, a limp of defense by antalgic reflex. The antalgic gait is not associated exclusively with coxalgia. It is seen in all conditions causing instability of the hip. It is frequent in congenital dislocations of the hip particularly in those cases of subluxation in which the phenomena of arthritis predominate over those due to interference with the static equilibrium. The authors have frequently seen patients with bilateral congenital dislocation of the hip present the Trendelenburg sign on one side and the antalgic limp on the other or show the antalgic limp only periodically. The antalgic limp is an indication of the degree

of irritability of the fibrous neocapsule in coxalgia, or of the deformed capsule of congenital dislocation of the hip. It is for the same reason that the antalgic gait characterizes the limp of those with arthritis deformans of the hip. Here again the antalgic movement makes possible the avoidance of pain. Theoretically it is impossible to have an antalgic gait when the hip is firm and capable of transmitting the weight of the body to the lower extremity. There is no antalgic gait when coxalgic conditions terminate in a true bony ankylosis, either spontaneous or operative (arthrodesis). The antalgic gait is slight in certain cases when, contrary to the rule, the *gluteus medius* has conserved an important functional value and especially in the cases in which the neocapsule is formed of tissue so tight that the ankylosis seems complete and comparable to a bony ankylosis. The antalgic gait may vary in a given case. For example, fatigue markedly aggravates the antalgic gait, which may appear after a long walk in patients who usually do not show it. Also, like rheumatic manifestations, the antalgic gait undergoes variations in relation to meteorological conditions.

**Hydrochloric Acid for Enhancing Calcification.**—Cornell and his colleagues observed reduced gastric acidity and decrease in the volume of gastric contents in eight cases of fractured bones with excessive osseous atrophy and delayed calcification at the sites of fracture. Five of these cases were treated with hydrochloric acid. The addition of hydrochloric acid (from 4 to 8 cc of a 10 per cent solution three times a day) to a diet high in calcium and vitamins increased the absorption of calcium and furthered the calcification of bone.

**Gastric Secretion in Chronic Alcoholic Addiction.**—Seymour and his colleagues studied the gastric secretion of forty chronic alcoholic addicts (from seven to forty years). Histamine was used as a secretory stimulant. The fasting volume of their gastric juice on repeated intubation was scanty and in the majority of cases was rather thick and ropy. A volume of 20 cc or less was found in 71 per cent of the men. Twenty minutes after the injection of histamine the gastric juice was considerably more limpid and had increased in volume 50 per cent of the men showing 20 cc or more. Only two of the forty subjects had free acid in the fasting specimen. In the first analysis after histamine eighteen had free hydrochloric acid and twenty-two had none. Reintubation of all the latter was done after from one to three weeks had elapsed and seven of these showed free acid in the gastric juice after this period. Only three of the men showed no evidence of pepsin in the gastric juice after repeated analyses, and seven showed an absence of rennin. The mean digestion of albumin in the

thirty-seven cases was 35 mm. The patients were singularly free from gastrointestinal complaints. Thirty-two claimed to have good appetites, twelve complained of gas and eight complained of sour eructations. Intermittent nausea and vomiting were experienced by six. In none was there a history of sore tongue, cutaneous lesions or diarrhea nor was there any objective evidence of glossitis. Six patients complained of occasional numbness and burning sensations of the extremities, and none had any objective evidence of involvement of the peripheral nerves. The erythrocyte counts and hemoglobin determinations were normal in all. After repeated analyses on all subjects with achlorhydria after histamine in the initial analysis, seven yielded free hydrochloric acid after histamine following enforced abstinence from alcohol. This point suggests the relationship of the ingestion of large quantities of alcohol to the secretion of acid in the gastric juice. It is apparent from the authors' studies and those of other observers that the incidence of achlorhydria is far higher in addicts to alcohol with polyneuritis than in those with uncomplicated alcoholism.

**Urinary Excretion of Androgen After Testosterone Propionate**—Dorfman and Hamilton determined the excretion of urinary androgens following the treatment with testosterone propionate of two men having organic and functional evidence of deficient testicular secretion. The rapidity of the appearance and comparative levels of excretion after oral and intramuscular treatment, the percentage of recovery in the urine of the administered material and the urinary levels of androgens were studied. The first patient was a man aged 35 who had lived until this time with a single descended testis. Following surgical removal of the testis at the age of 35, castration phenomena appeared. The second patient was a sexually underdeveloped man aged 27 whose genitalia instead of undergoing atrophy had never developed. The testes did not respond to injections of 100 rat units of gonadotropic substance given three times a week for nine weeks. With intramuscular injections of 20 mg. of testosterone propionate daily, the first patient showed an increase in androgenic output to normal levels and clinical disappearance of castration phenomena. A twenty-four hour titer of 50 international units was obtained on the third day of administration. The average of six assays covering twelve of the thirty days of injection was 68.9 international units, with a range from 47 to 94 international units. Tablets containing from 60 to 120 mg. of testosterone propionate were given daily. Twenty-four hour urine readings gave as high as 500 international units of androgen in case 1 and 264 international units in case 2. These large excretions were not accompanied after oral intake by as good clinical relief as was obtained with one-sixth or one-seventh the amount taken intramuscularly and with lesser androgenic activity of the urine. Absorption of the large amounts of androgen can take place through the gastrointestinal tract with what appears to be rapid elimination through the kidneys. It is suggested that there may be a threshold for the substance in the body and that rapid disposition is made of an excess. Oral means of administration should be considered from the standpoint of material lost not only through the feces but also excreted in the urine. Urine assays as an indication of the presence of hormone in the body may be misleading if the hormone in the body is present only irregularly. A rough estimation of the percentage of the androgenic material recovered in the urine is 62 per cent if it is in the form of testosterone, 41.4 per cent if androsterone, and 62.4 per cent if the material given contains an equal amount of androsterone and dehydroisoandrosterone.

**Sulfanilamide in Respiratory Infections and Rheumatic Fever**—The experience of Coburn and Moore over the last ten years has shown that rheumatic subjects who escaped hemolytic streptococcus infections also escaped rheumatic fever. With this objective in mind they conducted studies in the prophylaxis of hemolytic streptococcus infections during the last two years. The data reported comprise experiments on guinea pigs and observations on eighty rheumatic subjects. The authors found that sulfanilamide administered to guinea pigs before or after the induction of streptococcal abscesses failed to sterilize the lesions. Sulfanilamide used prophylactically prevented spontaneous infections and either prevented or modified the development of induced hemolytic streptococcus

cervical adenitis in guinea pigs. Sulfanilamide administered to rheumatic subjects after the onset of streptococcal infections of the throat did not prevent rheumatic recrudescences. The possible prophylactic use of sulfanilamide was tested in eighty rheumatic children. Seventy-nine escaped hemolytic streptococcus infection and signs of rheumatic activity.

**Pyelitis in Pregnancy**—Eastman states that the symptoms produced by infections of the urinary tract in pregnancy may vary considerably from those of the same disease in the non-pregnant state. Hectic fever with chills, tenderness at the costovertebral angle, clumped white cells in the urine and colon bacillus bacteriuria are the main diagnostic signs. To be of diagnostic significance the pyuria should exceed fifty white cells per high power field and these should be in clumps. From a diagnostic point of view the only difficulty that arises occasionally is in differentiating pyelitis, which is usually on the right side from acute appendicitis. Appendicitis rarely strikes for the first time during pregnancy. If appendicitis does exist usually there is a history of previous attacks. In pyelitis the "spiking" temperature curve, the common occurrence of chills and the tenderness at the costovertebral angle are usually characteristic and the diagnosis ordinarily presents no great problem. In women suffering from pyelitis the fetal mortality is at least twice that usually encountered. Abortion and premature birth account for most of these deaths. When therapeutic abortion is considered in refractory cases this unfavorable outlook for the fetus must enter into the decision. The variety of therapeutic methods which have been advocated for the treatment of pyelitis in pregnancy is evidence in itself that an established and successful form of therapy is lacking. Actual cure of pyelitis during pregnancy is rarely possible since the atonic ureters with their content of static urine prove usually an insuperable handicap, and during this period only relief of the disease is possible. Treatment has two objectives: relief of stasis and urinary antisepsis. Forced drinking of water serves both these ends and is the most important single measure, both in the prophylaxis and in the treatment of the disease. Two glasses of water with each meal and the same at bedtime should be routine for every pregnant woman and during warm weather a larger intake is desirable. In the treatment of pyelitis the intake of fluid should exceed 4,500 cc daily (except when certain of the newer urinary antiseptics are used). The more important drugs and therapeutic measures used in the treatment of pyelitis are methenamine, alkalis, mandelic acid, sulfanilamide, solution of posterior pituitary, termination of pregnancy and drainage and lavage of the renal pelvis. Of these, sulfanilamide appears to be the best.

**Nutritional Anemia in an Industrial District**—In order to determine the incidence of iron deficiency anemia of infancy in a large industrial area of Glasgow, Hutchison studied the hemoglobin levels of 300 infants up to 1 year of age. The diets of these infants were not supplemented by iron and they were regarded by their mothers as healthy. The author's data show that 26 per cent of the breast-fed and 35 per cent of the bottle fed infants had hemoglobin values of at least 10 per cent below normal (Mackay) values for their respective ages. These percentages become much greater if infants less than 6 months old are excluded. The principal factors influencing the development of this type of anemia were undue prolongation of exclusive milk diet, low birth weight and infections. The importance of prophylaxis is stressed and a mixed diet (including broth, vegetable puree and egg yolk at 4 or 5 months), preceded by the administration of iron, is suggested as a method of preventing this type of anemia.

**Nonhemoglobin Cellular Iron in Anemia**—In a previous paper on the distribution of iron in blood Jenkins and Thomson suggested that the excess iron was a breakdown product derived from aging hemoglobin and that the rise of the nonhemoglobin cellular iron percentage found in most forms of anemia was due to a compensatory retention in the circulation of cells which had passed the normal life span of an erythrocyte. In this investigation the authors performed 110 blood examinations in twenty-four cases of anemia or hemorrhage. The results show that the nonhemoglobin cellular iron increases as the hemoglobin concentration falls and decreases as the latter rises. If the fluctuations of the nonhemoglobin cellular iron are expressions of a compensatory mechanism they should usually be independent of the cause of the anemia. A study of the results makes it clear that this is so, as a corollary the nonhemoglobin cellular iron is of no value as a means of differential diagnosis. The erythrocytic population is made up of cells of varying age and if in the course of recovery from an anemia there is at one stage an intense hematopoietic activity one would expect that the new cells, having no appreciable nonhemoglobin cellular iron would

depress the percentage to a point below the normal for a brief period a number of such instances are present (six cases). The result is due to the combined effects of an increased removal of aged cells, in itself causing a reduction in the nonhemoglobin cellular iron percentage, and the influx of a large number of new cells. A further expectation would be that the total cellular iron might actually fall if the hemoglobin rises sharply enough. Several such instances have been encountered. The fallacy of assuming that the hemoglobin concentration can be calculated from the total cellular iron is evident. The authors do not claim that the facts presented furnish formal experimental proof of the accuracy of the hypothesis, but they submit that all the data obtained so far can be explained rationally on that basis.

**Horsehair Sutures for Closure of Conjunctiva**—Hay has found horsehair extremely useful for closing the wound after inserting the glass globe in a Frost-Lang operation. No knots are required. Horsehair keeps the wound firmly closed in virtue of its rigidity, while it does not bunch up the conjunctiva like a silk purse-string suture. The same suture may be used with advantage for closing the wound in the conjunctiva after trephining.

**The Itch Sensation**—Bickford states that, when histamine enters the skin through a puncture, itching begins at the point of the puncture. The skin widely surrounding the puncture also undergoes a change, so that when gently rubbed it gives an abnormal itchy sensation. The former sensation is called spontaneous itching and the latter itchy skin. Itchy skin arises through a local nervous (axonic) pathway. This pathway is separate from that of hyperalgesia and the vascular flare. The nerves do not belong to the sympathetic system. Itchy skin has been found round all itching lesions examined, whether occurring naturally or produced deliberately. It is, therefore, considered to be an essential part of the sensation of itching. Itchy skin may be abolished by a degree of asphyxia which leaves spontaneous itching unaffected, a similar dissociation may be produced by cooling a nerve trunk. This indicates that the nerves carrying the two sensations are separate. The sensation of tickling shows a close association with itchy skin in these experiments. In clinical cases of sensory dissociation itchy skin is not detected in areas in which the sensation of tickling is lost, even though the sensation of touch may be retained. Spontaneous itching is not felt at a point at which pain to the prick of a pin is defective. The pain of tickling, spontaneous itching and itchy skin are all conveyed in the anterolateral tracts, since they all disappear when this is divided. A condition of the skin in which itching is inhibited is described. The inhibition is central in origin and is probably produced through the pain nerves.

**Food Poisoning in Egypt**—From a total of 117 cases of food poisoning observed during three months, Fahmy and his associates isolated fifteen organisms seven *Bacillus pyocyaneus*, six *Bacillus morganii*, one *Bacillus aertrycke* and one *Bacillus metadysenteriae*. Of fifty rats, three were found to be infected and five strains were isolated four *Bacillus aertrycke* and one *Bacillus morganii*. There is apparently no difference between the organisms isolated from rats in Egypt and those isolated elsewhere. Strains of Castellani's metadysentery group were found responsible for two fatal cases.

 Extrapleural Pneumothorax A Maurer and E de Switsch—p 1468

**Bilirubin Level and Pernicious Anemia**—Mills and Mawson found that the bilirubin content of the serum of pernicious anemia patients is considerably greater than that of normal persons. Of eighty-five patients with pernicious anemia 93 per cent had serum bilirubin greater than 0.4 mg per hundred cubic centimeters, whereas of eighty-five normal patients 91 per cent had less than 0.4 mg per hundred cubic centimeters. The serum bilirubin was  $0.31 \pm 0.02$  mg in normal persons and  $0.98 \pm 0.06$  mg in patients having pernicious anemia. In fifty-three cases of pernicious anemia controlled by liver therapy the serum bilirubin was  $0.31 \pm 0.03$  mg per hundred cubic centimeters. The most striking proof that a significant difference between the two groups of persons does exist is shown not by statistical analysis but by the fact that specific treatment of pernicious anemia causes a return of a previously raised serum bilirubin to a normal level. That such a return to normal does take place can only mean that a raised serum bilirubin is a true symptom of pernicious anemia.

**Treatment of Pellagra with Nicotinamide**—Alport and his associates treated fifteen patients with pellagra and dermatitis, and two with, presumably, pellagrous stomatitis with 1 Gm orally or 0.5 Gm by injection of nicotinamide. The acute lesions of the mucous membranes were promptly and rapidly improved. Improvement in the acute cutaneous lesions was slower. Chronic cutaneous lesions in friction areas and chronic atrophic changes in the tongue were only slightly affected. The appetite, mental condition and general physical health of all the patients were improved by the treatment. Headache, itching and warmth of the skin followed treatment of four patients and one patient had colic after the administration of 1 Gm of nicotinic acid, but the same dose of nicotinamide given two patients led only to transient headache.

- \*Infarct of Liver J F Martin, P F Girard and M Planchu—p 715  
 Primary Hematoma of Aortic Wall I Bouchut A Guichard and J Bourret—p 727

**Infarct of Liver**—Martin and his associates point out that infarcts of the liver are extremely rare. As they were able to find reports of only seven cases, they describe two new cases that were observed in 1938. They give detailed clinical histories of the two cases and describe the postmortem aspects. The two hepatic infarcts were as different as could be one was red, circumscribed and triangular and its aspects corresponded well to the classic description. The other was white, diffuse and of irregular outline. It differed in all points from the cases reported heretofore, for the red infarct is the most frequent type. After describing the microscopic aspects of the two types of infarcts the authors give their attention to the etiology and pathogenesis, pointing out that they are difficult to explain. The double circulation of the liver, the arterial and the portal systems, create peculiar anatomic conditions, which however render the study of hepatic infarcts useful for a knowledge of the causes of infarcts in general. The authors regard as important the frequency of infectious endocarditis which they observed in two of four cases. Moreover, the large white infarct seemed to be connected with a dissecting aneurysm of the thoraco abdominal aorta in a patient with hypertension. It is by an arteritic process that hepatic infarct is most frequently brought about. However, it remains difficult to explain the extreme rarity of infarct of the liver. At first it seems justified to explain this rarity by the double circulation in the liver, for theoretically it seems necessary that obliteration of an arterial branch and of a portal branch would have to concur. After citing some experimental studies on the functions of the double circulation of the liver, the authors show that the results of these experiments are discordant and that it is difficult to explain the hepatic infarct by a simple mechanism. They regard as of primary importance the role assumed by the nervous element. They call attention to the rich nervous plexus which surrounds the hepatic artery and show that the anatomoclinical observations indicate the primary role of the periarterial nervous system. Among other factors they point out that whereas in the red infarct arterial obliteration was evident, in the case of the white infarct it was disputable. In the latter case the dissecting aneurysm was the most important vascular lesion and this produced a dislocation of the periaortic nervous plexus.

- Insulin Storage of Sugar L Bugnard and C Soula—p 1913  
 \*Role of B<sub>1</sub> Hypovitaminosis in Cardiovascular Pathology G Bickel—p 1916  
 Painful Syndrome of Right Hypochondrium in Course of Gonococcal Adnexitis E Mauro—p 1919

**B<sub>1</sub> Hypovitaminosis in Cardiovascular Pathology**—Bickel observed the disappearance of severe cardiac dilatation accompanied by cantering rhythm, simultaneously with the alcoholic polyneuritis, after the cardiotonic treatment had been interrupted and the patient was treated only with vitamin. The author shows further that the great importance of circulatory symptoms in the symptomatology of classic B<sub>1</sub> avitaminosis, beriberi, justifies a search for cardiovascular involvement in numerous disorders due to a partial deficit of vitamin B<sub>1</sub>. He made studies on patients with polyneuritis of alcoholic and gravidic origin and discovered that cardiac disturbances may become manifest in alcoholic addicts and in pregnant women in the absence of nervous symptoms other than diminution in the tendon reflexes and a slight weakness in the legs. On the other hand, these patients almost always present a certain degree of anorexia or of other gastrointestinal disturbances, which are early symptoms of a B<sub>1</sub> hypovitaminosis. After discussing the cardiovascular disorders of chronic alcoholism, the author takes up the cardiac disturbances of pregnancy, which, when they appear independent of valvular, arterial or renal disorders, should always suggest a deficit in the intake or utilization of vitamin B<sub>1</sub>. To be sure, the cardiovascular

disturbances of purely gravidic origin, that is, independent of all preexisting cardiac disorders, are usually less severe than those which appear in alcoholism. Nevertheless the author observed a favorable effect of the administration of vitamin B<sub>1</sub> in several women who, during the fourth or fifth month of pregnancy, developed tachycardia, cardiac erethism and slight dilatation of the heart, symptoms which generally are attributed merely to mechanical or toxic causes. After pointing out that cardiac disorders of hypovitaminotic origin occasionally are observed also in diabetes, in hyperthyroidism, in febrile diseases with grave denutrition, in certain gastrointestinal disturbances and so on, the author makes remarks about the mechanism by which the B<sub>1</sub> hypovitaminosis might give rise to the circulatory disorders and then discusses the therapy. He says that the rapid and complete cure of the cardiovascular disturbances requires comparatively large doses of vitamin B<sub>1</sub>, at first from 10 to 20 mg should be administered daily by injection. Beginning with the third week, that is, after a sufficient amelioration has been obtained, vitamin B<sub>1</sub> is given by mouth in combination with a suitable diet.

Postoperative Deficit in Weight Eventual Sequel of Gastrectomy for Ulcer. P. Santy and P. Mallet-Guy —p 1

\*Value of Cutaneous Reaction in Tuberculous Milieu. P. Foucaud —p 5

**Cutaneous Reaction in Tuberculosis**—Foucaud says that the cutaneous reaction for tuberculosis has been in use for about twelve years and that most pediatricians agree that the percentages of positive or negative reactions depend on factors such as (1) the housing conditions, the proportion of positive cutaneous reactions being much lower in rural sections than in urban and densely populated sections, (2) the mode of life, in that among the well-to-do, even in the cities, the percentage of positivity is much lower than among the poorer classes, (3) the type of material in which the tests are made in presumably healthy subjects (schools, group of students or of workers) positive results are detected in a much smaller percentage than in subjects from an infected milieu such as in those who come to medical services and dispensaries. The author's studies, which were begun in 1934, were made on the one hand on children who came from surroundings in which infection was suspected and who were referred to his dispensary by physicians for completion of the diagnosis and, on the other hand, on school children. The majority of children were from rural regions. Tests were made on 1,020 children ranging in age from several months to 18 years. The antecedents and the living conditions were known. The cutaneous tests were made at the time of the first examination. If negative they were repeated after three months if it was supposed that the infection was masked by a transitory state of anergy or was made the first time during a preallergic period when, for instance, the tuberculous contact had been removed. The results of the tests are recorded in tables. In the conclusion the author stresses the points which he was able to verify with maximum exactitude. 1 A positive cutaneous reaction indicates a tuberculous infection in the environment, the more so if the child is quite young. 2 The child represents the biologic evidence of familial tuberculosis in that the positive cutaneous reaction in a child permits the detection of tuberculosis in its familial surroundings. 3 The onset of school age and the age of puberty seem to be the periods during which the child is most exposed to tuberculous infection and to tuberculous disease. 4 A considerable number of children living in the surroundings of persons who excrete tubercle bacilli retain a negative cutaneous reaction. A table compares the incidence of positive reactions according to the type of tuberculous contact the children were exposed to: (a) persons with pulmonary tuberculosis who excrete bacilli, (b) persons with pulmonary tuberculosis who do not and (c) persons with visceral and osseous tuberculosis. 5 A considerable quantity of bacilli are necessary to provoke a positive cutaneous reaction in certain children. 6 The change of the cutaneous reaction is produced only in an infected milieu, it is produced rarely and slowly, this fact can be explained by a natural resistance to the bacillus without manifestation. The immunity thus conferred is slow but lasting.

\*Comparative Study of 350 Benign and Malignant Tumors of Mammary Gland. P. Desaise —p 533  
Septicopyemia of the Newborn and of Nurslings. J. Bottin —p 573

**Tumors of Mammary Gland**—Desaise presents a comparative study of 350 cases of benign and malignant tumors of the mammary gland. In the course of this report he advances a certain number of facts which now militate for a correlation between the two types and then again for their absolute independence. Among the first he cites the fact that fibro adenomas usually precede the development of cancer, for, whereas the average age of women with fibro-adenoma of the breast is 37 years, that of the women with cancer of the breast is 52 years. This fact makes probable the transformation of the first into the second type. The coincidence of the preferential site of the two forms of tumors in the superior external quadrant of the left breast and the observation of a direct transformation of a fibro-adenoma into cancer are additional factors indicating a correlation. Factors which militate against a correlation are the anatomopathologic independence of the fibro-adenoma, which is transplantable and is not dependent on a simple process of involution of the gland, the extremely different behavior of the two neoplasms as regards the time factor, the one being benign and of indefinite duration, the other one malignant and of limited duration, the noticeable divergences between the hormonal influences exerted on the two types of tumors, the fibro-adenoma developing chiefly during the period of ovarian activity and the cancer during or after the menopause, finally the possibility of interpreting as simply accidental the cases of association of fibro-adenoma and cancer. The author is inclined to consider as problematic the existence of the etiologic complex fibro-adenoma cancer, he thinks that the two tumorous processes have different if not opposite causes. He then raises the question whether, on the basis of this opinion, it would be justified to advise abstinence from surgical treatment in mammary fibro-adenoma and try in such cases medical treatment, based on glandular therapy and especially on the search of a perfect equilibrium between the ovary and the anterior hypophysis. Taking this position seems premature to the author for three reasons. 1 The exact mode of endocrine action on the genesis of benign mammary tumors is still unknown. 2 At the onset, the differentiation between benign and malignant tumors is impossible without recourse to biopsy. 3 The chances of atypical transformation constitute a danger for the patient with fibro-adenoma, because a more mutilating treatment may become necessary than the simple ablation of the small initial tumor. The author concludes that at the present state of knowledge the systematic ablation remains the best treatment in the presence of an apparently benign tumor of the mammary gland.

\*Behavior of Sugar Content of Cerebrospinal Fluid and Its Relation to Blood Sugar in Course of Insulin Coma in Schizophrenic Patients. M. Fischer —p 221

Psychology of Process of Suggestion. B. Stokvis —p 237

**Cerebrospinal and Blood Sugar During Insulin Coma**—Fischer says that, whereas the behavior of the sugar content of the blood during insulin shock therapy has been repeatedly investigated, little is as yet known about the behavior of the sugar content of the cerebrospinal fluid. He reports studies in fourteen cases and he arrives at the following conclusions. 1 In the course of insulin shock therapy there often develop considerable fluctuations in the fasting sugar values of the cerebrospinal fluid. A regular decrease in the fasting values was not proved by the author's investigations. 2 Like the blood sugar values the cerebrospinal fluid values decrease rapidly during the first hour, to be sure, the decrease in the cerebrospinal fluid is not quite as extensive and so the two curves either approach or cross each other during the second or third hour. 3 The glycochorrhachia shows a renewed decrease after two and one half hours, that is, at a time when the blood

sugar curve commences to increase again. 4 At the end of the coma the glycorrhachia is usually considerably lower than the blood sugar value and it rises much more slowly. 5 After the administration of sugar, the sugar content of the blood increases more rapidly than that of the cerebrospinal fluid. Although the blood may show a temporary hyperglycemia, the sugar content of the cerebrospinal fluid is more constant and in the author's cases it never exceeded normal values. Frequently the glycorrhachia was still quite low after the patient had wakened from the coma, this was the case even in the presence of hyperglycemia. Regaining consciousness is dependent not on the restoration of normal sugar values in the cerebrospinal fluid but probably on the reestablishment of normal endocrine conditions in the tissues, including the ganglion cell. Under certain conditions the sugar may reach abnormally high values also in the cerebrospinal fluid. In this connection the author cites a case observed by Molony and Honan, but even in this case it was observed that the sugar values of the cerebrospinal fluid do not fall and rise as quickly as do the sugar values of the blood, that is, they have a greater stability than do the sugar values of the blood. The author further cites results of punctures after spontaneous epileptic attacks and after attacks induced by metrazol. In the concluding summary he stresses once more that the sugar contents of the cerebrospinal fluid and of the blood do not determine the depth of the coma, as has been assumed by some investigators.

Technic for External Cholecystostomy P Cazzamali and R Pecco —p 501

**Arterial Symptoms in Phlebitis of Extremities**—Uggeri and Massone report three cases of arterial vasomotor reactions from thrombophlebitis of the legs and review the literature on the subject. They conclude that arterial reactions with ischemia may develop from thrombophlebitis of the extremities. They can be classified into three different groups: (1) in the course of phlebitis of long duration or during amelioration of the condition; (2) as sudden grave early symptoms of extensive thrombophlebitis of the main vein of the limb; and (3) in the course of aggravation of benign thrombophlebitis. Ischemia of the first type may be caused by arteritis (from dissemination of phlebitis), by arterial spasm (also induced by phlebitis) or by both arteritis and arterial spasm. It develops slowly. The arterial pulsation at the foot and at the posterior tibial and popliteal arteries generally cannot be felt and that of the femoral artery is weak, the oscillometric waves (Pachon) at the thigh and leg are absent. Both the arterial pulsations and the oscillometric waves improve by rest and proper treatment. Gangrene develops only in rare cases. Ischemia of the second type develops suddenly with symptoms of arterial embolism. It is due to reflex arterial spasm from venous occlusion. The arterial pulsations at the foot and at the posterior tibial and popliteal arteries and the oscillometric waves are absent from the beginning of the acute attack. The pulsation of the femoral artery may be felt weakly at the beginning of the attack and disappears as the condition is aggravated. The arteries in this type of ischemia show no pathologic changes. Ischemia of the third type is a benign arterial reaction to the venous condition. The diagnosis of the arterial reaction is simple in cases of the first and third groups. In cases of the second group (those which simulate arterial embolism) the diagnosis is made by the early appearance of cyanosis of the limb with blue and violet hues, which is different from the waxy pallor of the limb in arterial embolism. The treatment consists in administration of drugs aimed to control the arterial spasm. It is advisable to administer a daily dose of 0.5 or 0.6 Gm of acetylcholine in association with warm bathing of the limb or application of short wave irradiations or a morphine derivative. If this treatment fails, sympathetic treatment with procaine hydrochloride, peri-

arterial sympathectomy or resection of the occluded segment of the vein are indicated. Removal of the venous thrombus seems to be the ideal treatment in acute cases. However, further experiments are indicated in order to establish the probabilities of success of the procedure.

**Calcifying Tuberculosis of Spleen**—Von Orelli says that although splenic tuberculosis is occasionally discovered in the course of necropsies it is rarely diagnosed during life, because it is lacking in symptoms. He thinks that a diagnosis during life is possible only if the patient survives the splenic tuberculosis long enough, so that the tuberculous foci in the spleen undergo calcification and thus become detectable by x-rays. Since such cases are rare, he feels justified in reporting several in which clinical and x-ray examinations and in some also microscopic examinations justified the diagnosis of a calcified tuberculosis of the spleen. In four cases x-ray examination of the spleen revealed multiple calcified nodules in the spleen. To be sure, such shadows in the spleen have four possible explanations: they may be caused by calcified animal parasites, by phleboliths, by nonspecific calcified granulomas and by calcified tubercles. The author evaluates these possibilities in the reported cases. In three of his cases it became possible later to subject the calcified splenic nodules to microscopic studies. He found that neither the x-ray nor the microscopic examination permits a definite diagnosis. To be sure, in three cases general pathologic considerations made a calcifying splenic tuberculosis highly probable, however, in a fourth it proved difficult to render an exact differentiation from phleboliths and nonspecific calcified foci. Discussing the pathogenesis of calcifying splenic tuberculosis the author cites a fifth case which, strictly considered, does not belong to the aforementioned group of cases because there were no calcified splenic foci. However, observations in this case indicate that a general tuberculosis of the lymphatic apparatus plays a decisive part in the pathogenesis of splenic tuberculosis.

\*Risk and Advantages of Energetic Treatment with Neoarsphenamine and Bismuth Compounds C W Bottema —p 6014

Sodium Content of Blood Serum in Thyrogenic Degeneration of Liver J C M D Verschure —p 6021

**Combined Neoarsphenamine and Bismuth Therapy**—Bottema compares the risk involved in the energetic neoarsphenamine-bismuth treatment with the advantages of this method. He describes the disturbances which he observed in 1140 men of the navy who were subjected to energetic therapy with neoarsphenamine and bismuth compounds. The mortality of this treatment was found to be 0.087 per cent, the total morbidity was 4.6 per cent. The neoarsphenamine was chiefly responsible for the toxic complications, that is it caused all the deaths (0.087 per cent) and its morbidity rate was 3.9 per cent, bismuth compounds having a morbidity rate of 0.7 per cent. Of 647 patients observed for from five to seventeen years the mortality from syphilis was found to have decreased by 2.8 per cent and the morbidity (calculated on the basis of the patients with clinical signs, the cases only serologically positive being excluded) by 4.9 per cent. The advantages thus far outweigh the risks involved.

## The University of Michigan Medical Student

WARREN R. AUSTIN

Student in Class of 1940 University of Michigan  
Medical School

ANN ARBOR, MICH

During the one hour out of twenty-four (between 5 and 6 o'clock any evening) when even medical students become human beings, if an inquiring reporter were to drop in at one of Ann Arbor's eight medical fraternity houses he would be apt to find most of its members relaxing lazily on the davenports, grouped around the piano or, more probably, overbidding a weak bridge hand. By engaging in conversation the "dummy" at the sunporch bridge game, the interviewer would probably learn the following:

The student is a freshman in medical school, 21 years old but soon to celebrate his twenty-second birthday anniversary. He may or may not be helping his family in financing his schooling by outside work. He is almost sure to be unmarried, is very apt to be a Michigan resident and there is a 50-50 chance that he has a college degree. There is also an even chance that he will be seen in church on the following Sunday. He will probably state that he spends from \$2 to \$5 each month on social activities, most of which will find its way to the till of one of Ann Arbor's five modest cinema palaces. The remainder probably goes for occasional university or fraternity dances. Probably he does not "go for" the concerts and lectures sponsored by the university. The entire cost of his first year he estimates at from \$600 to \$1,000, with emphasis on the higher figure. Out of this he would probably budget his room cost at from \$150 to \$200 and his board at from \$250 to \$300. He is not sure how much his clothes will cost him during this first year but guesses at anywhere from \$50 to \$150. He is very apt to choose gross anatomy as his favorite subject thus far in his career. His premedical grade average is approximately B.

Over at the grand piano, a young man pauses a few moments to offer this information:

As an "average" sophomore, he is between 22 and 23 years old and the chances are good that he is doing some outside work along with his studies, although he is also leaning pretty heavily on the family for aid. He too is apt to be single and a Michigan resident. While he is more apt to have a college degree, there is less chance that he will be seen with his freshman brother in church. He spends about the same on social activities as his beginning classmate, with emphasis on movies and dances, but he is "discovering" the concerts and lectures and may be attending one or both series. As for the total cost of his first year, he has already found out that his budget had been rather slim and that \$700 was about the lowest figure he could spend, with \$1,000 a more workable figure. However, he has learned to make his room money go further but the board figure remains about the same. His freshman extravagance at the Ann Arbor haberdasheries is standing him in good stead, so that his clothes cost will average about \$50 less this year. He is even more likely to choose anatomy as his favorite subject now, although there is a definite leaning toward such new studies as pathology and biochemistry. His premedical average too was about B, and he probably finished his first year in the middle third of the class.

In another corner a young man is smiling over the Tonics and Sedatives in THE JOURNAL. He lays the magazine aside to give these facts:

Nearly 24 years old, he is a junior in medical school and probably just got back from several hours of extracurricular work. By this work he is able to lean less on his family for financial support than he had the year before. Although nearly a fourth of his classmates have been married during the previous summer, he is still single and probably claims Michigan as his home. He is almost sure to have a college degree and, more than any of his brothers from the other classes, is probably a regular church

The author received help and cooperation from Miss Vera Cummings and (Mrs.) Joyce Stanchfield of the Medical Office and Dr. Bradley M. Patten of the Anatomy Department in the preparation and distribution of the questionnaires. Dean Albert C. Lurstenberg and Dr. H. Marvin Pollard gave encouragement and suggestions.

attendant. He too spends on the average from \$2 to \$5 for his social activities, although not infrequently this figure may be around \$10. He is like as not to spend much of this on movies and dances but, with his future place in community life constantly in mind, he finds it stimulating to be a rather regular attendant at the concerts and lectures. Legitimate stage plays in Detroit not infrequently cut into his social fund. Although he still finds that \$1,000 is about the average yearly cost of schooling, he has learned in his two previous years how to "cut corners" and may be able to shave this figure down to as low as \$500. His room cost is about the same as during his sophomore year but his board is apt to have risen slightly, since he must occasionally eat at the hospital instead of getting back to "the house" for his paid-for meals. His clothes cost is still less this year, probably being no more than \$25 to \$50. Although he is now spending his entire time in the hospital, he has not yet had enough of any one course to pick an outstanding clinical favorite and he probably will choose pathology as his favorite subject, but he still remembers his anatomy dissections with fondness, internal medicine courses are beginning to strike his fancy. His premedical grades were probably mostly A's and B's and he seems to have had a few more of the former than his underclassman brothers.

Just as the first dinner chimes are sounded a rather earnest young man hurries in from the hospital. As he climbs to his room, doffs his white coat and prepares for supper, he tells his story.

Having just learned of his acceptance as an intern for the following year, this senior feels far more mature than his 24 years. The chances are even that he is doing some outside work and he finds that more than at any other time, except during his sophomore year, he is having to depend on his family for financial aid, he has probably borrowed some money to complete his last year. Nearly a third of his classmates are married but he is still a bachelor and, probably, a native of Michigan. He probably boasts a college degree but attends church less than any of his less advanced classmates. He is less apt to overstep a \$2 to \$5 monthly budget for social activities than his junior friends and so attends movies and dances more and the concerts, lectures and plays less. One thousand dollars is still his annual average cost of school, although he finds that this figure sometimes goes a little higher during his final year. His benedick friends are finding that their housing costs are mounting to such figures as \$250 and \$300, but he is still paying about the same as in previous years, his meals too are about the same as before. He is spending less for clothes (from \$25 to \$50 yearly, with emphasis on the smaller

figure) than at any other time during his medical school career. Having sampled the entire curriculum, the odds are that he will favor his medicine courses, especially those entailing clinical work, but surgery is a close second in his choice, just nosing out obstetrics and gynecology. Pathology still ranks high in his favor and he has still fond recollections of his gross anatomy days. He too probably entered medical school with a previous average of B.

Statistics leading to the foregoing information were obtained by circulating nearly 500 questionnaires among the four classes of the University of Michigan Medical School during November and December 1938. While the distribution and collection of these questionnaires had the approval and cooperation of the medical office, they are in no way official, having been circulated by me to obtain information which I believe is both interesting and informational to both students and faculty. Any inaccuracies must therefore be placed on my doorstep. Information that I gleaned from the questionnaires was supplemented through personal interview among students taken at random from the several classes. Verbal information closely coincided with that obtained in the written forms and apparently serves to authenticate the latter. While slightly less than half the entire student body returned completely filled in questionnaires, the number who furnished partial information and the additional personal interviews represents a majority of the medical students. The fact that of the total number who filled in questionnaires there was approximately one third in each of the three "grade divisions" of each class also serves to verify the belief that the information is a true cross-sectional picture of this medical school.

Official figures show the total enrolment of the University of Michigan Medical School to be 475, of which forty are women. Class enrolment figures are 121 freshmen, 125 sophomores, 127 juniors and 102 seniors. Of these 40 per cent returned completed questionnaires. With additional personal interviews, the total answering was about 60 per cent.

While the foregoing word pictures of "average" Michigan medical students may be regarded as typical, the extremes in each category varied widely. The questionnaire, entitled "University of Michigan Medical School Census," was marked confidential. It was explained that while answers were not obligatory they would be appreciated, and that additional details might be written on the back of the sheet. The questions covered the following points:

General Information—Class Entrance date Age  
Sex Married or single Children Nationality City-  
zen? Home city and state Other medical schools  
Premedical school Degree Full-time student? Local

address fraternity, own home, apartment, rooming house, elsewhere Church Member? Attend? Fraternity, social and/or medical Member Pledge Date

**Social Activities**—Approximate cost per month Principally movies, dances, plays or what? Attending concert series, lectures, Detroit legitimate plays, other events? Approximate annual cost of clothes, room, board Other hobbies with approximate cost

**Scholarship**—Approximate grade average in pre-medical school Class standing First year, second year and third year in class of how many? Honor point average of all work Favorite subjects in medical school Grades

**Outside Work**—Percentage of self support Type of work and hours per week, with salary, for each year and summer school Summer work Approximate annual cost of school attendance each year Method of financing medical education Whether willing to give more details on personal interview

Information on these points is presented under the separate headings as they appeared on the questionnaire

#### GENERAL INFORMATION

**Age**—Freshmen range, 20 to 29, 37 per cent 21, 28 per cent 22 Sophomores range, 20 to 33, 33 per cent 22, 22 per cent 23 Juniors range, 21 to 31, 29 per cent 23, 29 per cent 24 Seniors range, 21 to 37, 38 per cent 24, 29 per cent 25

**Married Students**—Freshmen 7 per cent, sophomores 11 per cent, juniors 27 per cent, seniors 32 per cent

**Residents of Michigan**—Freshmen 82 per cent, sophomores 70 per cent, juniors 79 per cent, seniors 76 per cent

**Literary School Degrees**—Freshmen 56 per cent, sophomores 70 per cent, juniors 86 per cent, seniors 82 per cent

**Medical Fraternity Membership**—Freshmen 78 per cent, sophomores 78 per cent, juniors 74 per cent, seniors 69 per cent

**Church Attendance**—Freshmen 49 per cent, sophomores 44 per cent, juniors 56 per cent, seniors 41 per cent

#### SOCIAL ACTIVITIES

**Monthly Cost** Freshmen range, 0 to \$20, 40 per cent \$2-\$5, 24 per cent \$6-\$10 Sophomores range, 0 to \$30, 52 per cent \$2-\$5, 19 per cent \$6-\$10 Juniors range, 0 to \$50, 42 per cent \$2-\$5, 33 per cent \$6-\$10 Seniors range, \$2 to \$25, 51 per cent \$2-\$5 33 per cent \$6-\$20

**Type** Freshmen movies 71 per cent, dances 38 per cent, concerts 7 per cent, lectures 5 per cent, plays 1 per cent, various 19 per cent Sophomores movies 60 per cent, dances 33 per cent, lectures 11 per cent, concerts 15 per cent, plays 11 per cent, various 22 per cent Juniors movies 52 per cent, dances 29 per cent, concerts 37 per cent, lectures 33 per cent, plays 23 per cent, various 2 per cent Seniors movies 54 per cent, dances 38 per cent, concerts 30 per cent, lectures 30 per cent, plays 35 per cent, various 2 per cent

#### SCHOLARSHIP

**Premedical Grade Average** (students' own estimate) —Freshmen A, 11+ per cent, B, 79 per cent, C, 8+ per cent Sophomores A, 11 per cent, B, 78 per cent, C, 11 per cent Juniors A, 15 per cent, B, 63 per cent, C, 19 per cent Seniors A, 11 per cent, B, 78 per cent, C, 11 per cent

**Class Standing**—As was expected, approximately one third of each class fell into each of the hypothetical grade divisions the upper, middle and lower third The majority of the students remained in the

same division throughout their four years It was hoped that the questionnaires might bring out a relationship between class standing and age of the student, but careful survey of the data shows about the same distribution in each of the three grade divisions as in the class as a whole

**Favorite Subject** (only those chosen by 5 per cent or more) —Freshmen anatomy 41 per cent, biochemistry 19 per cent, embryology 10 per cent, histology 5 per cent Sophomores anatomy 52 per cent, pathology 26 per cent, biochemistry 22 per cent, physiology 19 per cent, bacteriology 7 per cent Juniors pathology 31 per cent, medicine 23 per cent, anatomy 17 per cent, obstetrics 12 per cent, physiology 10 per cent, surgery 10 per cent, biochemistry 8 per cent, physical diagnosis 6 per cent Seniors medicine 54 per cent, surgery 30 per cent, obstetrics and gynecology 24 per cent, pathology 11 per cent, anatomy 8 per cent, pediatrics 8 per cent, biochemistry 5 per cent physiology 5 per cent, psychiatry 5 per cent All classes medicine 36 per cent, anatomy 30 per cent, pathology 24 per cent, surgery 19 per cent, obstetrics and gynecology 18 per cent, biochemistry 14 per cent (These percentages include only those classes which have already studied the courses voted on) Other subjects voted for by 3 per cent or more of any one class included clinical microscopy, public health, neuroanatomy and ophthalmology

#### EXPENSES

**First Year**—Freshmen range, \$250 to \$1,300, 35 per cent \$600 to \$1,000 Sophomores range, \$300 to \$1,300, 59 per cent \$700 to \$1,000 Juniors range, \$500 to \$2,500, 60 per cent \$800 to \$1,200 Seniors range, \$260 to \$1,250, 68 per cent \$600 to \$1,000

**Second Year**—Sophomores Too few estimated to make figures reliable Juniors range, \$400 to \$2,500, 62 per cent \$500 to \$1,000 Seniors range, \$260 to \$1,400, 62 per cent \$600 to 1,000

**Third Year**—Juniors Too few estimated to make figures reliable Seniors range, \$260 to \$1,200, 70 per cent \$600 to \$1,100

**Fourth Year**—Seniors (estimates) range, \$260 to \$1,200, 46 per cent \$600 to \$1,000

**Room**—Freshmen range, 0 to \$450, 48 per cent \$150 to \$200 Three per cent worked for their room Sophomores range, 0 to \$400, 60 per cent \$150 to \$175, 4 per cent worked for their room Juniors range, 0 to \$684, 50 per cent \$150 to \$175, 8 per cent worked for their room Seniors range, 0 to \$400, 54 per cent \$250 to \$350, 19 per cent worked for their room (Those living at home listed their room expenses as zero)

**Board**—Freshmen range, 0 to \$400, 45 per cent \$250 to \$300, 11 per cent worked for their meals Sophomores range, 0 to \$400, 63 per cent \$175 to \$300, 15 per cent worked for their meals Juniors range, 0 to \$1,140, 52 per cent \$200 to \$300, 19 per cent worked for their meals Seniors range, 0 to \$400, 62 per cent \$200 to \$300, 24 per cent worked for their meals

**Clothes**—Freshmen range, 0 to \$300, 31 per cent \$25-\$50, 27 per cent \$75-\$100, 35 per cent \$100-\$150 Sophomores range, 0 to \$150, 41 per cent \$25-\$50, 48 per cent \$75-\$100 Juniors range, 0 to \$300, 33 per cent \$25-\$50, 66 per cent varied widely Seniors range, \$10 to \$300, 53 per cent \$25-\$50, 47 per cent varied widely

**Method of Financing Medical School**—Freshmen family aid 58 per cent, borrowing 15 per cent, inheritance, bonds or trust fund 8 per cent, outside work 51 per cent Sophomores family aid 85 per cent, borrowing 7 per cent, inheritance, bonds or trust fund 7 per cent, outside work 52 per cent Juniors family aid 68 per cent, borrowing 29 per cent, inheritance, bonds or trust fund 8 per cent, outside work 40 per cent

cent Seniors family aid 74 per cent, borrowing 38 per cent, outside work 44 per cent, about 3 per cent partially financed themselves as blood donors

#### OUTSIDE WORK (DURING SCHOOL YEAR)

*Working*—Freshmen 51 per cent, sophomores 59 per cent, juniors 60 per cent, seniors 54 per cent

*One Hundred Per Cent Self Supporting*—Freshmen 14 per cent, sophomores 11 per cent, juniors 23 per cent, seniors 11 per cent

*Seventy-Five Per Cent Self Supporting*—Freshmen 11 per cent, sophomores 11 per cent, juniors 12 per cent, seniors 16 per cent

*Fifty Per Cent Self Supporting*—Freshmen 4 per cent, sophomores 11 per cent, juniors 2 per cent, seniors 16 per cent

*Twenty-Five Per Cent Self Supporting*—Freshmen 25 per cent, sophomores 26 per cent, juniors 23 per cent, seniors 11 per cent

*Type of Work*—Waiting table and washing dishes is the most common Other common jobs externship, assistant in university laboratories, laboratory work in hospital and/or doctor's office, NIA, assistant diener, selling medical books and instruments, orderly in hospital, fraternity house manager, fraternity "store," donor for transfusions, instructor, janitor, caretaker, life insurance work, practice of dentistry, subject for medical experiments, usher at university affairs, store clerk, music teacher, carrying paper route

*Relation of Outside Work (during school attendance) and Grades*—Freshmen Premedical average of A 7 per cent worked outside Premedical average of B, 42 per cent worked Premedical average of C, none worked

Sophomores Premedical average A, 5 per cent worked, B, 59 per cent worked, C, 11 per cent worked

Freshman average Upper third of class, 80 per cent worked Middle third, 40 per cent worked Lower third, 50 per cent worked

Juniors Premedical average A, 19 per cent worked, B, 62 per cent worked, C, 21 per cent worked

Freshman average Upper third, 66 per cent worked Middle third, 40 per cent worked Lower third 80 per cent worked

Sophomore average Upper third, 80 per cent worked Middle third, 60 per cent worked Lower third, 65 per cent worked

Seniors Premedical average A, 50 per cent worked, B, 80 per cent worked, C, 8 per cent worked

Freshman average Upper third, 85 per cent worked Middle third, 75 per cent worked Lower third, 1 per cent worked

Sophomore average Upper third, 92 per cent worked Middle third, 37 per cent worked Lower third, 25 per cent worked

Junior average Upper third, 99 per cent worked Middle third, 37 per cent worked Lower third, 25 per cent worked

Although analysis of these figures is somewhat difficult, the tendency appears to be toward higher grades for those students who are working their way through school, in whole or in part

#### COMMENT

Surveys and questionnaires of this kind suggest infinite possibilities which might be revealing as well as interesting I had originally intended only to find the percentage of working students, but the frequent discussions by groups of students have convinced me that medical students are keenly interested in how their fellow students live In my opinion it would be of great interest if a similar census would be taken in other medical schools Fair warning should be given any student, however, who anticipates such an undertaking that the preparation, distribution and collection of the questionnaires, together with the problem of shaping the data into presentable form, entail many hours of tedious work and that the project is hardly one to be undertaken during the busy school year

1414 Washington Heights, Ann Arbor (home address, Seattle)

## Comments and Reviews

### TEACHING THE MEDICOSOCIAL ASPECTS OF CASES

*Abridgment of an article by Dr George P Reynolds, instructor in medicine at Harvard University Medical School, Boston published in the New England Journal of Medicine, Jan 5, 1939*

Medicine is not a science which can be practiced by the precise methods of reasoning and deduction of the mathematician, the chemist or the physicist The human reaction to external or internal factors is a variable which prevents the accurate relation between cause and effect that characterizes the work of the true scientist The innumerable social, economic, psychiatric and physical elements of each situation make ever changing the reaction of the human being even during the course of a brief illness

Emphasis in the teaching of medicine on the physical and laboratory approach to disease obscures the importance of methods and quali-

ties which enabled the old fashioned family doctor to bring solace and tranquility to patients and to discover factors in their illness which would not have been revealed by the most complete modern laboratory studies

Clinical medicine is taught principally in the wards and outpatient departments From the point of view of the study of disease the public hospital is the best place for such teaching The difficulty is that in these surroundings the patient is likely to be stripped of his personality, his human relationships and the complexities of his own particular life and environment The student and even the instructor tend to speak of him, for example, as a "case of gastric ulcer" They fail properly to investigate the economic, occupational, social and psychological problems that he is facing and that may bear on the etiology and treatment of his illness

There is a tendency to speak of all symptoms as either functional or organic and to base their

treatment on this arbitrary method of classification. Few physicians seem to realize that environmental factors often cause dysfunction of an organ and that dysfunction may result in a lesion. There is much evidence that anxiety may lead to gastric hyperacidity and eventually to gastric ulcer, that exacerbations of arthritis frequently follow prolonged periods of mental or physical overactivity and that arterial hypertension is frequently found in the high pressure type of individual. A summary of the social service investigation and the recommendations resulting from it should be incorporated in the patient's record in as routine a manner as are consultations from medical specialists.

The lack of a proper liaison between the physician and the social worker hides from the student and house officer the importance of considering the social aspects of each case before drawing conclusions as to diagnosis and management. The physician whose experience has been confined to patients within a hospital is prone to look on the social service department as a charitable endeavor to better the lot of poor patients. This is erroneous, as similar social problems arise among well-to-do patients.

This criticism does not imply that attempts to teach the medicosocial approach to medical problems have not been made. Instructors at various schools have given lectures in recent years on this aspect of medicine. But the social approach to the study of cases has received insufficient emphasis in the education of medical students and has been totally neglected by many instructors. The need is to permeate the entire curriculum with such teaching rather than to confine it to any one department. We should adopt a more humane rather than a purely material attitude toward the problem of the individual. We should return to greater emphasis on the health and happiness of the patient as the primary aim of medical practice, but not at the expense of minimizing the importance of the control or cure of disease. We should develop in students a consciousness of the importance of the social aspects of medicine, bring them to realize their responsibilities as physicians not only to the patient but to his family, the community and humanity, and teach them how to elicit and evaluate scientifically the social factors of the individual case and to demonstrate how to construct a plan of treatment that is socially and medically adequate to the individual patient.

#### IMPORTANCE OF SOCIAL ASPECTS

The value of social study in diagnosis, the part it plays in determining the exact treatment of the case and its role in the prevention of disease and psychologic maladjustments must be demonstrated to students so that they may see clearly that this is an integral part of medicine, not merely an allied field of social endeavor.

Students must learn that social service departments were created because this aspect of the cases of indigent patients was being neglected by busy physicians and that social service departments represent merely a dissemination of the function of the physician. The study and evaluation of the social component of each medical problem is, moreover, a duty which the physician has to assume unaided in dealing with his private patients.

#### REALIZATION OF RESPONSIBILITIES

Students frequently ask: Is it the physician's duty to go into family affairs so remotely connected with the patient's disease? Doesn't his responsibility end with the treatment of that disease? Doesn't this belong to the field of preventive medicine, psychiatry or a social welfare agency? To answer them it is necessary to give students a view of the whole field of medicine, at one end of which is the chemist, the bacteriologist and the physiologist, next comes the trained clinical investigator, and near him stands the public health officer striving to prevent disease in the community. In the middle are the more limited aspects of practice, the specialist who attacks patients' problems from one point of view. At the other end of the picture is the psychoanalyst, who deals with the abnormalities of intellect and the emotions—the field so stupidly described as functional disorders. The work of each touches that of all the others. Every human being has his own psychologic peculiarities. Throughout the whole panorama we have the internist or the general practitioner, who serves as liaison between all the other groups and who must occasionally take an active role in the work of each group. The cardiologist has not helped his patient when he advises a sedentary life or "light work" to an individual who has a family to support and whose only means of livelihood is moving furniture. If, through his knowledge of the patient, through social agencies or by any other means a cardiologist finds some employment for the patient compatible with his physical limitations, he has more fully performed his function as a physician. Thus he would aid not only the patient but also his family and the community, which would otherwise have been obliged to care for them all. Such considerations as these, illustrated by actual cases, should convince the student of his responsibility as a physician and his duty to society as well as to the individual. Then he will see that it is part of the duty of physicians to act at times as public health officers, at others as psychiatrists, and to try to prevent disease as well as to cure it. Then the student will realize that he must often become involved in social situations apparently remote from his patient's disease.

Evaluation of the social data in relation to the patient's ailment depends first on the physi-

cian's ability to elicit the story. The student must realize that the usual brief summary of the social, marital, economic and occupational history found in hospital records is inadequate. Knowledge of the patient's ambitions, hobbies, interests, contacts, moods, thinking processes and his ability to adjust himself to the handicaps which his illness imposes should be evaluated. The physician or social worker seldom expects to gain all this information at the first visit, and if the patient is acutely ill perhaps little or none can be learned from members of the family. Brief conversations with his companions may reveal factors deeply affecting the patient's psychologic environment.

One is handicapped if the patient is seen only in the physician's office or the hospital. In private practice it may be desirable to seek an excuse to see the patient in his home or in his business environment. Although this is seldom possible to arrange for the student, its significance should be impressed on him.

The value of these factors in the treatment of the sick cannot be overemphasized. I mentioned their importance a few years ago, and further thought on the subject has strengthened my convictions. Today with an ever increasing number of tests and diagnostic procedures we are too prone to forget the importance of treating the patient as a whole man and to see his problems from his point of view. An illness which to us is trivial may fill him with terror. On the other hand his apparent success in any field may be far short of his aim, or his ambition may lie in an entirely different direction. Eliciting the social history demands tact, patience and keen perception. Its evaluation requires imagination, experience and the ability to see the problems through the patient's eyes.

#### DEVELOPMENT OF AN ADEQUATE PLAN OF TREATMENT

The weakest point in treatment in a public hospital usually develops at the time of the patient's discharge. The planning of after-care is usually left to a house officer whose medical experience has been limited to hospital work. The first step in planning the after-care is to give the patient or his family a thorough understanding of his illness, its resulting limitations, their probable duration and their implications with regard to his future. It is frequently advisable to pass much of this information on to relatives rather than to the patient. However, it is the patient who must make the adjustment and carry out the instructions, and he must be given as complete an understanding of his situation and the reasons for each limitation as is consistent with his welfare.

An intelligent police officer who had been recuperating from a coronary thrombosis was about to be discharged. The intern reported that the patient had been given a thorough

understanding of the nature of his condition and its limitations, that he had arranged to retire from police work and that his future convalescence had been carefully planned for him. Partly to demonstrate to the students the details of such planning and partly to elicit the patient's reaction to his limitations, the visiting physician asked him what he was going to do when he went home that afternoon. "Put the wife and kids in the car and start for California. We ought to make 200 miles before dark" was the surprising answer. Further questioning revealed no understanding of the situation by the patient or by the intern. The intern apparently assumed that all policemen are patrolmen and had informed the patient that his work was not compatible with the degree of cardiac damage he had suffered, and that he should resign and spend the next few months "sitting around outdoors." The patient had been attached to police headquarters, where his duties were almost entirely clerical, and this sedentary life he thought had been the cause of his illness. To him driving eight hours a day was a pleasant way of "sitting around outdoors." With proper planning, his retirement was changed to a leave of absence, his convalescence was completed at home, and he was then able to return to his previous work with slight modifications. The intern had entirely failed to acquire or to give the patient an understanding of the medicosocial situation and had allowed the patient to develop for himself a most undesirable program of after-care.

It is often more important for the plan of treatment to be practical for the patient and his family, and compatible with his financial and occupational resources, than for it to be the ideal therapy for his disease. The office worker may be unable to take milk and cream every hour but can arrange for a bland diet, regular meals and repeated periods of relaxation, which are often as effective in the treatment of peptic ulcer. A wage earner with diabetes may not be able to enter a hospital for regulation of his disease or be able to weigh his food, but such individuals can frequently be treated successfully while at work and can learn to estimate the composition of food intake with sufficient accuracy to permit insulin therapy.

#### METHODS

The methods of teaching the social component of medicine vary widely. The instruction is given by many different departments of some medical schools and by social workers without the aid of physicians in others. It is attempted variously by lectures, medicosocial ward rounds, case studies, case presentations, conferences and in some instances visits to the home. Each has its own advantages. The method of teaching will depend on the peculiar abilities of the indi-

vidual and the situation at a particular medical center. The essential is to present to the student the approach to his cases in the most effective way.

Deliberation on the methods employed in other clinics, together with experiences at the Harvard unit of the Boston City Hospital, has led to certain general conclusions.

The teaching of the medicosocial aspects of cases is most effective if conducted by a physician rather than by a social worker alone.

The function of the social worker in such teaching should be subsidiary to, though in close association with, that of the clinician.

The case method of presentation, whether on ward rounds, in outpatient departments or in conference, is more suited to this teaching than didactic lectures alone.

The subject should not be introduced as a separate entity but in close correlation with the purely medical aspects of a disease or a case.

The ultimate aim is to have such teaching permeate the whole medical curriculum in all discussions that deal with diagnosis, prognosis, treatment and the prevention of illness.

## WELCOME TO THE FRESHMAN CLASS

*Abridgment of an address by Dr Everts A. Graham, Babby Professor of Surgery, to the Freshman Class of Washington University School of Medicine, St. Louis, Sept. 21, 1938*

Each one of you holds a place that was sought by eight others. Some have been actuated by the humanitarian ideal of relieving an individual of the handicaps of illness, others are inspired by the scientific aspects of medicine and a desire to gain the satisfaction that goes with making some discovery. Perhaps some have been led to make this choice because of family traditions.

As one who has watched the careers of many students I offer some advice. Medicine is a full time career from the moment one enters on it. It is a jealous god expecting to receive from its votaries all their talent and energy, and lavishing no rewards on those who are not fully consecrated to its service. Unless one feels that one is led into this profession by an enthusiasm and a zeal which will not be satisfied with any other kind of work, it would be better to select another career. Those who have undertaken the study of medicine in a spirit of indifference and without the zeal demanded usually become tragic figures in later life. The faculty recognizes this principle and believes it is acting in a spirit of kindness when, after it is apparent that an individual is unsuited for a medical career, it advises him to withdraw and to enter some other field of activity.

To you who are about to begin the fascinating and engrossing study of medicine, the oppor-

tunities for personal satisfaction are greater than have ever before existed. On the clinical side opportunities exist as never before really to make a diagnosis and to do something rational and effective to cure the patient. The humanitarian yearning is therefore more easily satisfied now than it could have been even twenty-five years ago. The x-rays, our principal diagnostic agent, are less than fifty years old, and surgery, our most dramatic method of treatment, is scarcely any older in its modern sense.

## MANY NEW FIELDS

Scientific medicine is developing so rapidly and so many new fields of investigation are being discovered that almost any one with a good intellect and with proper training can make some new observation or discovery. If the discovery is considered by others to be important, the thrill cannot be equaled by the acquisition of wealth or by rewards generally sought after by those who, in other careers, are less fortunate than we votaries of medicine. The scientific view of disease is scarcely a century old. Before that time the study of medicine consisted largely of learning the dogmas of recognized authorities. Galen's writings were unchallenged for a thousand years. In our country almost up to the Civil War Benjamin Rush was considered an almost infallible authority. He assumed that there is fundamentally only one disease, albeit with different manifestations, and that one form of treatment, bleeding, sufficed for all disease. The medical student's work then was simple compared with that which we expect of you. At that time the student could inherit his books from his grandfather and still be up to date. Because of the tremendous pace at which medical knowledge is accumulating, some of the textbooks which you will purchase will be more or less obsolete by the time of your graduation. A few years ago Dr. Singer, Dr. Ballou and I were persuaded by a publishing house to write a book on chest surgery. This is the newest field of surgery and there was no adequate book on the subject. We undertook our work with enthusiasm but promptly found that no sooner had we completed and set aside one chapter to prepare the next than we had to go back again to the finished chapter to add new knowledge that was constantly being contributed in the literature of the world. There was a constant stream of new facts being added. It appeared as if we never could finish the book because of our inability to finish one chapter. We finally succeeded in completing the manuscript by agreeing that no literature after a certain date would be quoted. The book appeared three years ago but already it is obsolete. My own ideas of many aspects of chest surgery have so changed in this brief time

that I should prefer not to have any one read certain parts of the book today. This experience will convince you, I think, of how rapidly changing the knowledge of medicine is. In your clinics in the senior year, if you hear some physiology expounded which seems discordant to that which you learned as a sophomore, don't jump to the conclusion that we clinicians don't know our physiology. Give us a break by assuming that maybe in the two years that have elapsed the accepted concepts have changed.

You are now beginning the study of medicine, but you will never finish it. Even after graduation you must still be earnest and hard working students. You must acquire the habit of good reading. Do not confine yourselves to the perusal of advertisements of pharmaceutical firms but read regularly several journals which pertain to fields in which you have a special interest. Those who will become clinicians I would urge to read some journals outside the clinical field and a monograph now and then on some special aspect of medicine. Those who are not going to be clinicians I would likewise urge to read some good clinical journals. After all, clinical medicine is only applied anatomy, physiology, pathology and bacteriology. A good clinician must be reasonably well versed in those sciences, and if he is to be progressive he must keep abreast of their new developments. This may sound like an arduous task. On the contrary, one who is a true votary will have an unconquerable urge to try to keep abreast of the times. The strong hand of this jealous god will lead him to his reading as irresistibly as if he were being led by a ring in his nose.

#### A USE FOR USELESS KNOWLEDGE

I hope that you may remember some of these remarks during the next two years, because you will probably wonder what practical use some of the work expected of you can have. "How can the study of the reactions of a nerve in the hind leg of a frog have anything to do with curing a man of appendicitis?" you may ask. Well, there are fundamentals that every good doctor must know. A clinical picture of, say, appendicitis is built up on a structure of fundamentals of the medical sciences. A disease of any organ in the body is not confined to that organ but exerts its effects on the whole body. A knowledge of the fundamental reactions of the structures of the body is useful practical knowledge to the clinician. A child may fail to see the value to him of learning the multiplication table, but we elders know its value. Moreover, as Abraham Flexner has repeatedly emphasized, there is a use for useless knowledge. Faraday's discoveries in electricity at the time seemed to be merely additions to useless knowledge, but they created a new era of civilization. Could any one have predicted

that the Wright Brothers machine flown at Kitty Hawk, N. C., could in less than a lifetime threaten the security of Great Britain and in a sense annul the long accepted influence of sea power? These are examples of useless knowledge. The faculty of your school will endeavor to avoid as much as possible expecting you to learn things which can never possibly be useful to you. We feel, however, that probably we are better judges than you are of what should be taught in a medical school.

To be a well educated doctor, more than reading is necessary. Attendance at medical meetings is important. From hearing and seeing new work presented often far more inspiration is obtained than merely from reading reports. Inspiration is obtained also from the opportunities to see "in person" the great and to make the acquaintance of your colleagues. Travel to well known institutions and clinics is also a stimulating experience. One can always learn from the other fellow.

In stressing the importance of concentration on your medical work I have not meant to omit another desirable aspect of a doctor's education. The stress of modern civilization and the enormous expansion of medical knowledge have to some extent done something to make us as a class lose our general culture. It is shocking to find medical students who are not even well versed in their native language. Many cannot spell correctly in either written or spoken English. Doctors of medicine are a group who have probably devoted more years to their education than any other group. It would be a pity if the specialized education should drive out the general cultural education which at one time was supposed to be a prerequisite to the study of medicine. For your own satisfaction and recreation I would advise, in less busy moments, the cultivation of the muses. Read good literature, exercise your talents in art, music and poetry. Accomplishment in these fields will bring satisfaction and solace in many dark moments.

I should like to speak of some of the rewards of a medical career. From the time of the ancient Greeks the profession of medicine has been closely identified with that of teaching. Students flocked to the masters for instruction and thus medical knowledge was passed on from one generation to another. The medical school, as we think of it, is comparatively modern. To many an enormous satisfaction is obtained from watching the development of pupils and from the feeling that perhaps in some measure one has contributed to the inspiration of the successful ones. Medicine now offers opportunities in executive positions, in public health activities, in the army and navy, in editorial positions. There are opportunities for many to obtain the reward of

personal satisfaction even if their inclinations lead them out of the main tent into the side-shows

There are some who think that as a group successful clinicians are rich. This is a mistaken idea. The number of those who have become wealthy through the practice of medicine is a very small fraction of one per cent of the total, and some of those have indulged in questionable procedures in order to make their riches. The signs of the times would indicate that even less than in the past will opportunities arise for becoming wealthy in this profession. Those of you who have entered this career because of the financial returns would do well to turn about now before you realize too acutely the disappointment.

I should like briefly to state my own ideas of the great physician. First of all in the requirements are those qualities which are embraced in the word character—honesty, integrity and moral instincts. Nothing is more horrible than a dishonest doctor, one who advises an operation that is not necessary merely to obtain a fee, one who wilfully misrepresents the results of an examination or one who bears false witness against his colleagues. The great doctor must also have wisdom. He must have a natural

instinct to avoid saying the wrong thing or at least saying the wrong thing in the wrong way. He must avoid unnecessarily terrifying his worried patients or their families. The wise doctor usually can be thoroughly honest and at the same time assuage the fears and worries of his patient even in a hopeless case. The great doctor must also, in the words of Paul, have faith, hope and charity, faith that the patient has a chance to get well, and charity toward the unreasonableness of a patient and his family as well as toward the financial calamity which often the illness has been to the patient. If I were choosing a doctor for myself I should prefer one with slightly less intelligence but with unquestioned character than one who is brilliant but of questionable integrity. That crookedness can exist in this noble profession perhaps is a shock to you. The vast majority of the doctors of my acquaintance, and it is a large one, are thoroughly trustworthy, but in a group of 150,000 persons there will be all gradations.

Probably never before has the doctor been so much respected as he is now. This is due in no small part to the revolution in medical education which occurred in this country about twenty-five years ago.

## Correspondence

### THE ART OF DIAGNOSIS

*To the Editor*—Permit me to discuss the article by Mr. Frank Cook, F.R.C.S., published under Comments and Reviews in the Student Section January 28, page 376.

Mr. Cook apparently has been associated with one of the medical colleges which has always placed England in the foremost ranks of educators of doctors. He admits his close relationship to the senior students and decries the lack of diagnostic intuition in those just entering the clinical field. Surgeon Cook then criticizes the system of organized (if somewhat standardized) method of approach adopted by the well trained medical student in investigating the complaints of patients.

Mr. Cook refers to the carefully organized clinical investigation of every patient, regardless of his complaint, as emanating from America and as inclined to stultify a clinician's initiative and relegate him to the permanent role of "clinical clerk."

It is disappointing to read these words from one of academic rank. American medical education has its defects, but not one of them can be attributed to the lapses mentioned by the author. The very features stressed in our educational system (careful histories, routine investigations from every angle and differential reasoning) are those which have placed graduates of our approved medical colleges and hospitals on a plane unequalled by any country. Only by frequent repetition of these procedures and careful serial notations do "clinical clerks" acquire acumen which eventually accords them those much cherished but

sometimes doubtful qualities referred to in Mr. Cook's comments. What else is "inductive reasoning" but reasoning based on careful, painstaking examination of a patient combined with clinical experience? The latter requisition requires years of accretion of bits of clinical observations based on careful investigations.

Mr. Cook refers to the "endless series of irrelevant and uninspired" notations as indicative of some one contemplating the "writing of a paper" or the attempt at hiding lack of wits under a "cloak of pseudo-scientific enterprise." One wonders. Has Mr. Cook failed in his attempt to inspire medical students? Nothing is more inspirational than the methods adopted whereby "clinical clerks" follow their staffs from bed to bed discussing these "series of irrelevant and uninspired clinical investigations" and by discussions and deductions arrive at conclusions which they do not hesitate to note in the clinical records. Further, these same groups are courageous enough to verify their deductions either under the microscope or in the autopsy room. Are these methods conducive or not to the "scantiest notion of diagnostic values?" In answer to Mr. Cook, at least at the Medical College of the University of Cincinnati (Cincinnati General Hospital) we do "go the whole hog" whenever it is at all possible. We do have every "available body fluid examined with reference to every chemical constituent and micro-organism known to science." In this way frequently the conclusion "I do not know" is reached, but only after careful appraisal of every sign and symptom.

JULIEN E. BENJAMIN, M.D., Cincinnati

## Medical College News

*Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section*

### Officers of Association of Medical Students

At the third annual meeting of the Association of Medical Students at Philadelphia, December 28-30, Mr Frawick H Stubbs, Emory University School of Medicine, Atlanta, and Mr David E Hepford, Temple University School of Medicine, Philadelphia, were elected co-presidents of the association for the ensuing year. The outgoing president was Mr William Dewey Davis, Division of Biological Sciences, University of Chicago. Mr Herbert K Abrams, University of Illinois College of Medicine, Chicago, was elected corresponding secretary, Miss Agnes Denholm, University of Illinois College of Medicine, Chicago, recording secretary, and Mr Alfred Russell Hurst, Division of Biological Sciences, University of Chicago, treasurer. The next annual meeting of the Association of Medical Students will be held at Wayne University School of Medicine, Detroit, in December 1939.

### Lectures to Students on Economics

A series of lectures on medical economics beginning January 27 will be given to the fourth year students at Louisiana State University School of Medicine, New Orleans. Dr Joseph Rigney D'Aunoy, dean of the school, announced that the first lecture dealing with life insurance was given by Mr Frank Limont, superintendent of agents of the Pan-American Life Insurance Company. Lectures will follow on systematic savings, bookkeeping, real estate as an investment, record and file systems and the income and distribution of physicians, given by Mr Fred Ellsworth of the Hibernia National Bank, Mr J Harry Rees of the Remington Rand Company, Mr Richard Foster of the Department of Public Welfare of New Orleans and Mr J E Blum Sr of the Louisiana Real Estate Board. Mrs Elizabeth Greenwald, record librarian of the Louisiana Charity Hospital, will give the final lecture on hospital records. The dean stated that these lectures were given for two reasons: first, the notorious inability of medical men to safeguard their own financial interests and, second, to link up the future physician's personal finances with the present widespread discussions of socialized medicine.

### Appointments at Tennessee

Dr Wilson L Williamson, associate professor of gynecology at the University of Tennessee College of Medicine, Memphis, has been appointed professor and head of the department to succeed the late Dr William T Black. Dr Williamson is a graduate of Tulane University of Louisiana School of Medicine, New Orleans, and a former president of the Tennessee State Medical Association. Dr Richmond McKinney, professor of otology, laryngology and rhinology in the college for many years, has resigned to devote all his time to private practice. His successor is Dr William Likely Simpson, associate professor of otology, laryngology and rhinology.

### College Cooperates with County Society

The dean of Wayne University College of Medicine, Detroit, in his last annual report stated that the school endeavors to cooperate in every possible way with the Wayne County Medical Society. The dean and members of the staff serve on various committees of the county organizations as well as the state medical

society. The faculty council includes many prominent members and officers of the society. It is recognized that the objectives of the society and the College of Medicine in relation to the improvement of medical education and medical service in the community are similar. There is therefore every reason for encouragement given to complete cooperation and understanding between the college and the society. Among the joint projects of the university and the society has been the establishment of a council or service for high school and college students who are interested in medicine as a career. The service will be under the direction of the division of student personnel of the university.

### Case Report Contest for Interns

The Allegheny County Medical Society, Pittsburgh, sponsors an annual case report contest which is open to all interns of any approved hospital in Allegheny County. The report should be of a case that has been under the care of the person submitting the report during his internship and should consist of not more than 1,000 words. The manuscript should bear an appropriate title for the report but nothing to indicate the identity of the writer. Attached to the manuscript should be a sealed envelope bearing the name of the writer, the hospital at which he is serving, the school and year of graduation and the initials or signature of the member of the staff in whose service the case was attended. The first prize will be \$25 and the second \$15. Manuscripts should be mailed prior to April 1, 1939, to the Secretary, Allegheny County Medical Society, Jenkins Arcade, Pittsburgh, marked "Case Report Contest."

### Woman's Medical College

Dr Winifred B Stewart, assistant clinical professor of neurology at Woman's Medical College of Pennsylvania, Philadelphia, has received an appointment to the psychopathic division of the department of neuropsychiatry of the Philadelphia General Hospital. —Mildred W S Schram, PhD, of the Donner International Cancer Foundation recently addressed the students of the Woman's Medical College of Pennsylvania on "Problems of Cancer Research." —Dr Catharine Macfarlane, professor of gynecology, addressed the Cancer Forum of the Lankenau Hospital Research Institute Nov 29, 1938, on "The Value of Periodic Pelvic Examinations."

### University of California

Dr George E Tucker, Los Angeles, recently lectured at the University of California Medical School, San Francisco, on "The Legal Aspects of the Practice of Medicine," "Medical Records and Their Legal Effect," "Medical Evidence in the Courts," "Malpractice Liabilities and Defenses and Other Civil Actions Against Physicians," "Medico-Legal Problems in Cases Involving Insurance," and "Medico-Legal Aspects of Workmen's Compensation." Only the senior class was required to attend these lectures, but they were attended by many members of the faculty and resident staff. —Dr James M D Olmsted, PhD, professor of physiology, who attended the recent sixteenth International Physiological Congress in Zurich, Switzerland, also engaged in research in France on the life of François Magendie, nineteenth century neurologist,

whose biography is now in preparation—Sherburne F Cook, Ph D, a Guggenheim Fellow, is in Mexico studying the influences of European civilization on the birth and death rates of the aboriginal population—Dr Stacy R Mettler, associate professor of medicine, is in England doing research on hematology in the laboratory of Dr L J Witts at the University of London

#### The Next Examination for the Army Medical Corps

The War Department has announced an examination, March 20-24, for the purpose of qualifying candidates for appointment as first lieutenants in the medical corps, regular army, to fill vacancies occurring during the next calendar year. The examination is open to all male graduates of acceptable medical schools who have completed one year's internship in an approved hospital or who will complete such an internship June 30 and who will not be over 32 years of age at the time it will be possible to tender a commission. Those doctors who do not complete their internships until June 30 will not be eligible for appointment until July 1. The examination will be conducted by boards of medical officers convened throughout the United States and will consist of a physical examination, a written examination in professional subjects and a determination of the candidates' adaptability for military service. Full information and application blanks will be furnished on request addressed to the Adjutant General, War Department, Washington, D C. Applications will not be considered after March 4.

#### Fiftieth Anniversary of Department of Biology

A dinner in celebration of the fiftieth anniversary of the founding of the department of biology at Western Reserve University and the fifty years of service there of Francis H Herrick, Ph D, now professor emeritus of biology, was held Dec 3, 1938. President Winfred G Leutner was toastmaster. Edwin G Conklin Ph D, executive vice president of the American Philosophical Society and professor emeritus of biology at Princeton University, gave the principal address.

#### National Board Questions in Pharmacology

Following are the questions used by the National Board of Medical Examiners in pharmacology and materia medica in part one of the examination held Sept 12-14, 1938:

Answer any six questions. 1. Discuss the action on the central nervous system of (a) caffeine citrate (b) atropine sulfate (c) digitalis and (d) picrotoxin. 2. State the sources of (a) theelin (estron), (b) prolan A and (c) prolan B. Discuss their actions. 3. Discuss the possible ways by which sulfanilamide may act as a germicidal agent. 4. State the symptoms of poisoning by (a) histamine (b) insulin and (c) carbon tetrachloride. 5. Discuss the difference in the action on metabolism of (a) thyroid extract and (b) dinitrophenol. 6. Explain the differences in the action on the uterus of (a) ergotamine and (b) an aqueous extract of ergot. 7. Discuss the arsenoxide theory of the action of arsenphenamine. 8. Explain the action on the coronary circulation of (a) nitroglycerin, (b) digitalis and (c) theobromine with sodium salicylate.

#### Intern Case Report Contest

The second annual intern case report contest for interns is open to all accredited east side hospitals in Detroit. Dr Cyril K Valade is chairman of the committee and Dr Ledru O Geib is honorary chairman. Other members of the committee are Drs George A Troester, William J Yott, Ralph A Johnson, William W MacGregor, Louis D Stern and Harold J F Kullman. The prizes are \$100, \$50 and \$25. The committee urges that the attending physicians at all the eligible hospitals encourage their interns to enter the contest and lend any necessary advice. The contest will close March 1.

#### Hutchings Hall Dedicated

A new building was dedicated Oct 5, 1938, at the Utica State Hospital, Utica, N Y, which bears the following inscription:

This building is named to commemorate the services of Richard Henry Hutchings, physician, teacher, administrator, superintendent of the Utica State Hospital, who has devoted his life to the welfare of the unfortunate.

At the dedication services were five upstate college presidents. The state of New York was represented by Dr William J Tiffany, Albany, commissioner, State Department of Mental Hygiene, and Dr Frederick W Parsons, New York, the former commissioner. John A DeCamp, superintendent of the Utica Public Schools, and Dr Herman G Weiskotten, dean and professor of pathology of the Syracuse University College of Medicine, also participated. In Hutchings Hall will be centered the educational and recreational activities which Dr Hutchings has developed in the administration of a great state hospital. Dr Hutchings graduated from the Bellevue Hospital Medical College, New York, in 1891, and has devoted thirty years of his service to the state of New York. He is now president of the American Psychiatric Association.

#### Student Clinic Day at Wayne University

The first Student Clinic Day at Wayne University School of Medicine, Detroit, was held Dec 15, 1938. Routine classes were dismissed so that students, faculty members and visiting alumni might participate in student-led discussions and demonstrations. The activities were in charge of the college chapter of the American Association of Medical Students.

The student council of the college held its semi-annual student-faculty-alumni reunion on the same day. The council correlated its reunion features with the day's program, serving a luncheon at the college and sponsoring a dinner and evening program at which awards were presented to recognize noteworthy work in the clinic.

#### Ohio Personals

Dr Tom D Spies, associate professor of medicine, University of Cincinnati College of Medicine, addressed the University of Wisconsin Medical Society, Madison, January 10 on "Recent Advances in the Study of Pellagra"—Associates of Dr Carl J Wiggers at Western Reserve University School of Medicine, Cleveland, gave a tea Nov 23, 1938, in honor of the twentieth anniversary of his appointment as professor of physiology. Dr Wiggers received a book of photographs and letters of appreciation from the president of the university, the dean of the school of medicine, members and former members of the staff of the department of physiology and students who have done special work under his tutelage.

#### Additions to Louisiana State University

About \$500,000 is to be expended on additions and alterations to the medical building of the Louisiana State University Medical Center, New Orleans, according to the dean, Dr Joseph Rigney D'Aunoy. The improvements are being financed jointly by the university and the PWA. The eighth floor of the building, which is now one third the size of the other floors, will be extended. The library space will be extended 90 by 50 feet. Quarters for experimental animals on the seventh floor are also being rebuilt, with its present space tripled. Complete overhauling of the heating system is included in the program, with individual controls installed for every classroom and laboratory. The distilled water, drainage and pumping systems will also be entirely overhauled.

## Ohio State Board Questions in Pathology

The following questions were used by the State Medical Board of Ohio in the examinations for licensure held at Columbus Dec 7-9, 1938

- 1 Discuss the use of vaccines for upper respiratory infections. How would you select or prepare the selected type?
- 2 What tests would you use in insuring the best results from urinary antiseptics, and why?
- 3 Describe the pathology of a tuberculous area in the lung.
- 4 Describe the changes that have taken place in a sclerotic artery.
- 5 Describe the microscopic picture of a well marked case of chronic glomerulonephritis.
- 6 What are the changes in a joint in hypertrophic arthritis?
- 7 What are the essential differences between benign and malignant tumors?
- 8 What frequent diseases are traceable to the milk supply and discuss the objectives of pasteurization.
- 9 Discuss the place of the family physician in cooperation with school authorities in an outbreak of diphtheria in a school in a small community.
- 10 Discuss the legal rights and restrictions in prescribing narcotic drugs.

## Nevada Personal

Russell Atkinson, president of the Nevada State Tuberculosis Association, spoke on community education on tuberculosis before students and faculty members at the University of Nevada recently under the auspices of a local chapter of Alpha Epsilon Delta, honorary premedical fraternity.

## Italian Chemist Comes to Wake Forest

Dr Camillo Artom, director of the physiologic institute of the University of Palermo in Sicily, has been appointed professor of biochemistry in the Wake Forest School of Medicine, Wake Forest, N C. He succeeds Herbert C Tidwell, Ph D, who resigned to go to Baylor University.

## Lectures on Pellagra

The second series of lectures under the John Wyckoff Lectureship at New York University College of Medicine, established by the Phi Delta Epsilon Fraternity, was presented Nov 21 and 22, 1938, by Dr Virgil P W Sydenstricker, professor of medicine, University of Georgia School of Medicine, Augusta. Dr Sydenstricker spoke on pellagra.

## Additions to Library at Loyola

More than 1,400 medical books and bound journals have been presented to Loyola University School of Medicine, Chicago, by Dr Henry Schmitz Sr and will form the nucleus of the new Memorial Library in the Mercy Hospital-Loyola University Clinics. Other additions to the library have been presented by Dr Carl F Schaub and Dr Abraham W Schram.

## Dr Banting Addresses Students

Sir Frederick G Banting, Toronto, discussed the value of research at a luncheon in Winnipeg, Man, Nov 29, 1938, under the auspices of the Winnipeg Medical Society. He also addressed students at the University of Manitoba Faculty of Medicine.

## Temple University

Under the auspices of the Association of Medical Students, Dr Eric M Matsner, New York, of the National Medical Council on Birth Control, addressed an open meeting in the Medical School Auditorium at Temple University, Philadelphia, January 26, on the subject "Control of Contraception and Preventive Medicine."

## South Carolina Personal

Dr Hillyer Rudisill Jr, professor of radiology at the Medical College of the State of South Carolina, Charleston, tendered his resignation effective February 1. Dr Rudisill has accepted a position as radiologist to the Piedmont Hospital, Atlanta, Ga. Dr Bernard S Kalypian, formerly assistant to Dr Rudisill, will succeed him.

## Officers of Alumni Association of Mayo Foundation

Dr Julius H P Gauss, Indianapolis, was elected president of the alumni association of the Mayo Foundation at the twentieth annual meeting held in Rochester, Minn. Other officers are Dr Lester D Powell of Des Moines, Iowa, first vice president, Dr George M Constans of Bismarck, N D, second vice president, Dr John Richards Aurelius of St Paul, reelected secretary, and Dr Duncan M Masson, Rochester, associate secretary and treasurer.

## Intern Alumni Day at Pawtucket

The Memorial Hospital, Pawtucket, held an intern alumni clinic day Nov 2, 1938. The morning was devoted to clinics by the staff. In the afternoon the following program was presented, with Dr John F Kenney, chief of the medical division, presiding:

- Dr Alexander Randall Philadelphia Obstructive Uropathy
- Dr William D Stroud Philadelphia Coronary Insufficiency
- Dr Harry Bond Wilmer Philadelphia Endocrine Therapy in the Treatment of Allergic Disorders
- Dr George M Piersol Philadelphia Acute Hepatic Cellular Disease

## New Building at Georgia

The new Classroom-Clinic Building at the University of Georgia School of Medicine, Augusta, was dedicated December 9. Dr Eugene E Murphey, professor of clinical medicine, was the principal speaker. Dr George Lombard Kelly, dean of the University of Georgia School of Medicine, presided.

## Promotions at New York University

The chancellor of New York University, Harry W Chase, LL D, announced recently the following promotions in the College of Medicine:

Dr Edward R Maloney to professor of dermatology and syphilology to succeed Dr Howard Fox, who retired to become professor emeritus. Dr Maloney has been a teacher at New York University for fifteen years.

Dr Clarence de la Chapelle to professor of medicine. Dr de la Chapelle, who has been on the faculty for thirteen years, received his education at Fordham University and at New York University and at present is acting director of the Third Medical Division at Bellevue Hospital, also chief of the cardiac clinic at Lenox Hill Hospital and consulting cardiologist at St Luke's Hospital, Newburgh.

- Dr Robert Gewanter, instructor in otorhinolaryngology
- Dr Stuart Z Hawkes, instructor in surgery
- Dr Irwin Edward Siris, assistant clinical professor of surgery
- Dr Leonard Goldwater, instructor in preventive medicine
- Dr T Campbell Hooton, assistant in anatomy
- Dr William Kaufmann, Dean W Horace Hoskins, fellow in comparative pathology

## Dr Howard T Karsner Honored

The associates and former pupils of Dr Howard T Karsner, director of the Institute of Pathology and for twenty-five years professor of pathology at Western Reserve University School of Medicine, Cleveland, commemorated his sixtieth birthday by presenting him with his portrait, painted by Rolf Stoll, head of the department of portraiture of the Cleveland School of Art. The event took place at a tea in honor of Dr and Mrs Karsner, January 6, at the Institute of Pathology. Preceding the tea, the faculty of the school of medicine gave a surprise luncheon at the Cleveland Club in honor of Dr Karsner.

## FRACTURE OF THE NECK OF THE FEMUR

MARTIN B TINKER, M D

AND

MARTIN B TINKER JR, M D

WITH THE COLLABORATION OF A T KERR, M D, AND  
PROF W M SAWDON

ITHACA, N Y

Fracture of the neck of the femur has the highest death rate of any simple fracture of the long bones in advanced middle age or old age. Crippling and permanent disability from nonunion and stiff joints have afflicted nearly half those who survive. The high mortality and serious disability have led to trial of operative internal fixation for many years, with increasing frequency during the past few years.

### RELATIVE RESULTS OF CONSERVATIVE AND OPERATIVE TREATMENT

Expert opinion was sought as to the relative value of conservative and of operative treatment by consulting textbooks devoted entirely to fractures and the sections devoted to fractures in systems of surgery.<sup>1</sup> There is uniform pessimism concerning prognosis and results, especially with patients over 60 years of age or afflicted with medical complications. All authorities report infrequent bony union and considerable disability. The greater number recommend Whitman's abduction method as the treatment of choice. No comprehensive statistics are given. Speed classes this fracture as the "unsolved fracture."

Recent surgical literature gives a somewhat different picture. 2,074 cases were collected from various sources.<sup>2</sup> Of the patients, 1,094 were conservatively

treated, most of them by the Whitman method, with an average of 51 per cent of bony union. This figure practically agrees with that of Bohler of Vienna, a widely recognized authority on fractures.

There were 980 patients treated operatively, and all methods were used—bone pegging, open operation with the Smith-Petersen nail, blind nailing with the Smith-Petersen nail, multiple nailing, and screw and bolt fixation. The average percentage of bony union was 78. Obviously, 27 per cent shows a substantial gain in bony union in favor of internal fixation, but this is far less than that shown by the percentages of a few experts: Moore 96, Johansson 93, Mathieu 92, Watson-Jones 91 and Bohler 88. Bone pegs have poorer results than stainless steel or ordinary steel devices. This study seems to give a fair cross section of the results which might be expected, for some surgeons report as few as two cases of treatment by their special method. When the skill is acquired which many surgeons have with conservative methods, poor results should be mainly from aseptic necrosis of the head and preexisting medical complications.

Read before the Section on Surgery General and Abdominal at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

Mortality is the question of first importance. Conservative methods give an average rate, taken from several sources, of approximately 25 per cent, while the average taken from 980 recent cases is only 9 per cent for blind nailing, a gain of 16 per cent. When it is remembered that cases for Whitman's abduction must

Fig 1—The templet disassembled with the nail which is used in the tail and three Moore pins

be carefully selected, with bad risks excluded, this figure becomes more significant, for no such careful selection is made by many advocates of internal fixation

#### FRACTURE OF THE NECK OF THE FEMUR IN SMALLER COMMUNITIES

Textbooks on fractures and the more important articles dealing with these injuries have all been based on the experience of fracture clinics in large cities and of orthopedic surgeons, specialists in bone and joint disease. At least one third of all fractures, however, must be treated by rural practitioners and small town surgeons, for transportation to the larger centers is impossible in many cases because of the serious general condition and the financial circumstances of the patient.

We have attempted to get an estimate from rural communities and the smaller cities by sending questionnaires to physicians within a radius of 100 miles from

#### Results of Treatment by Rural Practitioners and Surgeons in Small Cities

Form of Treatment	Good Results Without Use of Crutch or Cane Per centage	Fair Function With Crutch or Cane Per centage	Poor Function Patient About on Crutches Per centage	Patient Living Unable to Be About, Per centage	Patient Died Per centage
Fracture ignored	15.0	22.5	2.5	2.5	57.5
Sand bag	29.4	29.4	13.1	4.9	2.1
Buck's extension	6.8	23.8	3.9	2.7	12.8
Whitman's abduction	48.0	20.0	4.0	12.0	16.0
Anderson's splint	71.4	19.1			9.5
Smith-Petersen nail	23.5	14.2	14.2		42.8

Ithaca. These physicians are general practitioners and small town surgeons, whom we know personally, who have sent patients to us for various surgical operations, in more than one third of the instances either the physician or members of his family have been our patients. They are of better than average professional ability, as a group conscientious, and of wide general experience. The small town surgeons include some of exceptional education, training and experience, most of them lack the special experience of surgeons in large clinics and of orthopedists.

Reports of 573 cases have been received. All the physicians gave valuable information. Full data concerning results were given by 295. The forms of treatment and the percentage of good results in relation to

the number of patients treated by each method (not the total treated by all methods) are given in the accompanying table.

It will be noted that more than a third of the patients were treated by ignoring the fracture or using the sand bag because of their bad condition. These obviously makeshift methods of treatment cannot be expected to give satisfactory results. The death rate for these two methods (85.6) is very high, 57.5 per cent for disregard of the fracture and 28.1 per cent for treatment by sand bags. Even with these makeshift methods several recoveries with fair results are noted, there were 15 per cent of good results when the fracture was entirely ignored and 29.4 per cent when only sand bags were used. Several of the patients were over 80 years of age and in poor general health.

Buck's extension was the most commonly used procedure, nearly one third of the patients being treated by this method. Good results, walking without crutch or cane, were reported in 56 per cent of the cases, this percentage being approximately 9 per cent higher than that for the Whitman method in this series and also better than that usually reported. The death rate was approximately the same as that reported from large clinics, in spite of lack of facilities and nursing care in many cases. That the results of conservative methods are better than most reported from larger centers may be due in part to the sturdy character of the patients, most of whom were accustomed to hard work and plain living. Also it is fair to state that general practitioners of rural communities and the smaller cities generally give personal and faithful care to patients, in many instances better than that of an inexperienced intern.

Fig 2—The templet in position in the right femur with Moore pins or nails already inserted through guide tubes. The straight line down the center of the outer side of the femur in A shows how guide tubes 1 and 2 must be aligned for a bone on the right side. B a lateral view of the templet in place shows the apex of the templet (a) hooking over or cupping the line of the vastus externus.

The results did not approach the average for internal fixation by experienced operators. Most small town surgeons are conscientious enough not to undertake a surgical procedure of major importance when they feel that they lack experience or facilities, which doubtless accounts for the small number of operations. The need for roentgenograms in both the anteroposterior and the

lateral position cannot be met by most rural practitioners. Internal fixation was used in two cases with excellent results by a man of surgical experience and ability. It seems evident that most of the unfortunate results were due to lack of study of methods and lack of general surgical experience on the part of those who

Fig 3—Right femur. A first stage in removal of templet nail in tail pulled out and guide tubes unscrewed. B templet coming off leaving pins in place.

used them. We believe that if the men of the smaller cities would cooperate and refer their work to a few who, through study, an effort to acquire experience and natural aptitude, are fitted for special work, it would be possible to reduce the death rate decidedly and to save a great deal of unnecessary suffering and expense.

We report on five patients treated by internal fixation, all of whom survived operation. Only one of the five could have been considered a good risk for a major surgical procedure. The others were all of advanced age, with general conditions which contraindicated such a procedure.

#### REPORT OF CASES

**CASE 1**—A woman aged 69, admitted Jan 26, 1938, the day of fracture, was discharged April 9, after ten weeks and three days of hospitalization. A roentgenogram taken January 27 showed an intertrochanteric fracture, with a split off of the lesser trochanter. Nailing was performed February 10. There were marked senility and decrepitude, with kyphosis of the spine. The patient sat up in a chair two days after operation and walked on crutches seventeen days after operation. She had had a temperature of from 101 to 103.2 F continuously before the nailing. She could walk without crutch or cane four months after operation.

**CASE 2**—A woman aged 75, admitted March 11, 1938, two weeks after fracture, was discharged April 14, after four weeks and two days of hospitalization. A roentgenogram taken March 11 showed a medial fracture of the neck of the femur on the right side. March 14 nailing was performed. March 17, the third day after operation, the patient sat in a chair, and March 20, the sixth day, she walked on crutches. She had high blood pressure, dyspnea, arteriosclerosis and obesity. She was very happy at the relief of pain. She was still on crutches three months after operation.

**CASE 3**—A man aged 72, admitted Feb 28, 1938, the day of fracture, had nailing performed March 4. He sat up in a chair March 7, the third day, and walked on crutches March 14, the tenth day. There were myocardial degeneration, diabetes and arteriosclerosis. The patient was still in the hospital, with boils and urticaria, and still on crutches three months after operation.

**CASE 4**—A woman aged 57, admitted Sept 18, 1937, the day of fracture, and discharged November 18, was operated on September 23. The fracture was a simple, complete, transverse fracture of the neck of the right femur near the head. The first roentgenogram was taken September 18. A roentgenogram first suggested bony union November 7. The patient sat up in bed September 26, the seventh day after operation, and in a wheel chair October 5. She went back to bed on the advice of the roentgenologist, and she sat up again November 11. She walked on crutches November 15. There was no complicating physical or mental ailment. She walked without a cane or crutches in six months.

**CASE 5**—A woman aged 65, injured Oct 11, 1937, was admitted October 12. The first roentgenogram was taken the day of admission, and the first operation, nailing, was performed October 13. The nails were shortened October 15. An operation performed October 25 was necessitated by failure of the roentgenologist to take a lateral view. There was no serious physical handicap except marked obesity. The cooperation was poor. March 30 it was seen that absorption of bone around the nails with shortening and atrophy due to disuse had permitted the nails to penetrate into the acetabulum. The roentgenologist was doubtful as to whether union had occurred, but weight bearing was advised. The patient sat up in a wheel chair October 20 and walked on crutches November 23. She died nine months after operation of agranulocytosis or agranulocytic angina in association with infection of the mouth.

Fig 4—Left femur. A nuts screwed and wire applied to steady pins and prevent nuts from running off backward. B excess of pins cut off.

It seems evident that four of the five patients were of the class who generally, because of their serious condition, are treated by ignoring the fracture or at most are treated by sand bags and rest in bed.

#### A GUIDE (TEMPLET) FOR DIRECTING NAILS

The desirability of some appliance for directing nails, screws or other supporting devices so that they may be properly placed has been recognized by many surgeons. At least seven devices have been described, most of

which are too complicated and would be too expensive for the average surgeon of small city hospitals

Recognizing the importance of a simple appliance by means of which nails could be placed accurately, one of us (M B T Jr) devised a nail director, or templet. The one depicted is so constructed that it will guide three nails, as suggested by Austin Moore, by means of

Fig 5.—Right and left femur same patient demonstrating the marked structural difference between the two and showing that the appliance is adaptable to either side and that due allowance has been made in figuring the angles of the guide tubes or templet to provide for the variation. Roentgenograms of these bones (figs 6 and 7) prove that the pins are in a satisfactory position

three tubes which can be removed after the nails are in position. A study of the femur by Gaenslen (*Journal of Bone and Joint Surgery*) shows that the cross section of the neck, the target to be aimed at, is roughly 1.8 by 2.5 cm in diameter. It has been found by experiment with a large number of femurs that individual differences are not great, the templet has been successful in all cases in which it has been tried experimentally. Furthermore, it can be adjusted for use on the right or left side. A modification for use with a single Smith-Petersen nail or two small-flanged nails, as satisfactorily employed by Louis A. Goldstein of Strong Memorial Hospital, University of Rochester, we believe could be readily made. Patent has been applied for by the maker of the templet, Lawrence Scott of Ithaca, N. Y.

It is understood that the fracture must first be properly reduced. In using the templet, right or left femur, the upper curved end hooks over the vastus line. Guide tube 1 should be placed exactly over the middle of the femur. The upper opening of tube 1 is about one-fourth inch below the vastus line.<sup>3</sup>

For the right femur one places the drill through the guide tube and drills through the compact bone with the drill parallel to the surface of the operating table (figs 2 and 3). The templet must be so adjusted that the line between the drill hole already made and tube 2 will be parallel to the table and in the center line of the femur. A drill hole is then made through one of the smaller holes in the "tail" of the templet, and a small ordinary nail or some similar object is placed in this hole to hold the templet in position and prevent side

slip. A drill hole is made through the compact tissue of the femur through tube 2, and nails ("nail" is used by Moore instead of "pin" as shown in the illustration) are entered in tubes 1 and 2 to hold them in place. A third hole is then drilled, through tube 3, and the nail is placed.

If the left femur is to be operated on, tubes 1 and 3 are placed parallel to the edge of the table and on the center line of the femur, the nail for tube 2 being placed last (fig 4). When the nails have been inserted the templet can be removed by unscrewing the guide tubes and removing the nail in the tail section. Nails should be inserted at a distance approximately three-fourths inch less than the length of the neck as shown by a roentgenogram taken in the anteroposterior position after reduction. This is because the x-ray image is a projected one, larger than the bone itself, as stated by Moore. Resistance of the bony cortex indicates that the head has been reached.

Roentgenograms should now be taken in the anteroposterior and lateral positions to determine the angle and depth of the nails. If these are correct, nuts should be screwed on and the nails cut off to approximately one-eighth inch. The fracture can be impacted by one or two fairly sharp blows on the nails. A wire about the nails (fig 4) holds them and keeps them from spreading or withdrawing.

#### EXPERIMENTAL STUDY OF METHODS OF INTERNAL FIXATION

Determination of the relative value of the flanged nail (the Smith-Petersen nail, its modifications and other similar nails), of multiple nailing and of the use of screws was attempted by testing experimentally fractured fresh bones fixed by these methods. Resistance to force in the weight-bearing position and torsion were estimated in testing machines of the Department of

Fig 6.—Right femur pins in a satisfactory position

Experimental Engineering of Cornell University. A large amount of anatomic material furnished through Drs. A. T. Kerr and J. W. Papez of the Department of Anatomy, Cornell University, made this work possible. Tests of the strength of various methods of internal fixation were under the direction of Prof. Will Sawdon of the Department of Experimental Engineering. The

<sup>3</sup> Operative experience, after this paper was written, shows that nail number one would best be first placed and control of position made by x-ray examination. Then the templet is slipped over the nail and it will satisfactorily guide the other two nails.

placing of nails, screws, bolts and other appliances for internal fixation must be accurate, and results must be checked by roentgenograms in two planes. The neck of the femur was sawed through in an effort to determine how much the nails alone would hold, it is evident that when the bone is broken there are jagged points which when impacted act somewhat like the matching or dovetailing of wood. The Moore nails alone, with a sawed-smooth surface will carry a load of 100 pounds or more in some instances. Bones broken, nailed and

ratus and bed, which so frequently has led to fatal hypostatic pneumonia, (3) raising of the patient's morale, the relief from pain and the ability to move about freely greatly influencing the will to live as well as to recover function. These conditions have been met successfully by internal fixation in many cases by a number of surgeons.

#### ABSTRACT OF DISCUSSION

DR KELLOGG SPEED, Chicago. The scope of this paper, including as it does morbidity, mortality, choice of treatment and personal experience with internal fixation of fracture of the neck of the femur, makes it difficult to discuss. There seems no doubt that internal fixation has come to stay, that it will be practiced everywhere and that it is a godsend to many, in offering early freedom from pain and mental refuge in the faith in mechanical contrivance or fixation hopefully accepted by the patient, and often by the doctor, as a way out of an immediate difficulty. Ways and means of fixation are probably of secondary importance compared to these two factors, namely immediate relief of pain and restoration of confidence and mobility of varying degree for the patient. The choice of fixation lies with each physician who uses that type which may be employed best with the least disturbance of or trouble to the patient. Each agent flanged nail, metal pin, bone transplant, screw or other device, may be open to certain objections but at given distances throughout the country one should be able to find surgeons satisfactorily trained to use with reasonable safety one device or the other to alleviate human suffering in the presence of this frequently fatal fracture. Devices for directing the nail or pin are not fool proof, they have been in existence more than fifty years and are not yet universally adopted. The one essential, regardless of the agent of fixation or its method of introduction, is reduction of the fracture, controlled by the x-rays. The insertion of the internal agent must be done in conformity with strict aseptic principles and the final result as to bony union, viable head and freedom from secondary changes such as aseptic necrosis, flattening, loss of cartilage and ultimate painful coxitis, must lie in observation of the patient over a long period and a prolonged study of the condition and of retrieved specimens obtained after treatment. Internal fixation followed by early weight bearing seems to act at cross purposes. Some of the advocates of the method are now recanting their remarks on early weight bearing and restraining the patients for from sixteen to twenty-four weeks before allowing freedom in walking. A patient walking on crutches may be a long way from complete cure when bony union or the health of his bone is concerned, but at least he is alive and active. Study of clinical results, coupled with progressing pathologic study, will eventually give practitioners better control of this fracture.

DR E W CLEARY, San Francisco. The authors are to be complimented on the courage and determination with which they have pursued this investigation and on the ingenious device used for directing the Moore nails. Dr Austin Moore himself feels that no such device is necessary for directing the nails—that he can guide their introduction as he puts them in by feeling with the hand chuck that he uses. I have verified this observation. I agree with the authors that internal fixation is the great problem in dealing with this fracture today. The procedure falls into four different steps. I agree with Dr Speed that the first step is reduction. After reduction there must be some means of accurately localizing the position of the fractured bone as well as determining the extent of the reduction, and then there must be some means by which the surgeon can bring the information afforded by the localizing x-rays into his operating field in order that he may so place his fixation device as to be sure of its effectiveness. Some years ago I started to work on a device which would first of all hold the reduced fracture in a preferred position for x-ray localization and for the surgeon's subsequent fixation. The advantages of the flexed thigh position had already been emphasized. I found no adequate device for holding the leg in this position, and with a great deal of trial and hard work I have developed an accessory table which is an effective aid in the three last of

Fig 7—Left femur pins in a satisfactory position

impacted have carried much greater loads, up to 300 pounds. Smith-Petersen nailing carried about the same load as the least efficient Moore nailing.

The conclusions to be drawn from the experimental work, as summarized by Professor Sawdon, were as follows: 1. Repair of actual fracture with proper reduction gives much greater support than does repair with sawed or smooth surfaces. 2. Support rendered by cancellous bone is much greater than would be expected. 3. There is a distinct spring, or elastic property, to the Moore nails which tends to restore the fracture to the original position after compression. 4. There is a considerable load capacity to the Moore nails after apparent yielding of the fracture. 5. There is little elastic property in the Smith-Petersen nail, and consequently there is crushing or destruction of the cancellous bone and distinctly less recovery. 6. The exact position of the Moore nail is not of fundamental importance in determining its holding capacity. 7. The Moore nail has better contact-holding properties than the Smith-Petersen nail or, in other words, is better able to hold fractured fragments together, since the Smith-Petersen nail is easily withdrawn after the test. Pliers were required to extract the Moore nails in every case, even after vigorous testing, while the Smith-Petersen nail could be withdrawn easily with the thumb and forefinger.

In essence these conclusions signify that the Smith-Petersen nail does not hold the fractured surfaces in apposition as well as the Moore nail and hence does not provide the opportunity for union.

Important considerations related to recovery are (1) immediate relief from pain and surgical shock, (2) immediate freedom from confinement in fixation appa-

the four steps in dealing with this fracture. It fixes the patient and holds the reduced fracture firmly in position for the operation. It provides for standardized x-ray localization in two planes, and it provides by means of exact mechanical instruments, which may be sterilized, for the transfer of the exact x-ray localization into the aseptic field of operation, where it is utilized by the surgeon in directing the nail or fixation device of whatever character he may choose.

DR. WALTER G. STERN, Cleveland. Fifteen years ago Dr. Phil Kreuscher and I advocated the then rather new method advanced by Dr. Royal Whitman of New York, which consists in complete reduction of the deformity caused by the fracture by means of extension, internal rotation and abduction of the femur and fixation of the limb in this position until either union has taken place or nonunion has been found inevitable. These principles are as sound today as they were then, so that today only the method of fixation is being debated. To some of the members this "immolation in plaster" is a terrible thing. They never apply the casts themselves and do not have the mechanical apparatus to care for cases in which casts are required, or the family does not care to put a hook in the ceiling to lift the bed so that the patient can be standing up part of the time. Therefore they have gone back to something easier and more comfortable, internal fixation by means of metal devices. J. B. Murphy forty-five years ago advocated the use of the then new round wire nail, and I have roentgenograms of the second patient in whom he used a nail forty-four years ago. Nonunion was the result, and the man walked on that nonunited limb for twenty years and worked as a roller in a rolling mill until the nail got so badly bent that I had to take it out. Jones of Grass Valley, Calif., and Roger Anderson of Seattle have also worked on this problem of fixation by means of the "well leg traction" methods, and for a while some surgeons thought that this might be the solution, but the thing gets away from one, the reduced bones are not kept in position to heal and the method had to be abandoned. M. N. Smith-Petersen revived the old and discarded method of nailing the fragments together, with an ingenious three-flanged nail, the chief advantage of which lies in the fact that when it is well placed in a solid head it really prevents the rotation of the fragments on each other. I am going to issue a word of warning. Even under local anesthesia with old persons the introduction of pins or nails is a major operation. One of the major medical societies will soon come out with the results of a questionnaire on this subject in which it will be seen that the death rate from internal fixation in these cases is 9 per cent plus. A method which is rapidly becoming popular in Europe is the high Schanz osteotomy, sometimes called the Lorenz bifurcation or Watson-Jones subtrochanteric osteotomy.

DR. MARTIN B. TINKER, Ithaca, N. Y. I am much gratified by the active discussion which our paper has provoked. The careful preparation of all the discussions has added much to the value of the presentation. No surgical method is perfect, all have their weak points. With regard to the remarks of Dr. Stern, it seems to me that one is reverting when one contemplates subtrochanteric osteotomy. He mentioned the danger of shock even with local anesthesia, on account of the time required. What does one get into with subtrochanteric osteotomy? That is a major procedure to begin with, whereas in the hands of surgeons who properly qualify themselves this other operation need not last a long time and need not be associated with much shock. Moore operated in thirty-five minutes and has had no operative deaths in sixty-nine cases in which he has used his pins. Sven Johannsen of Sweden, who has reported more than a hundred cases in which he himself has used the Smith-Petersen nail, had a mortality of 9 per cent. It seems therefore that when all is said and done it is a question of the surgeon's preparation properly to perform this technic, whether it is with the Smith-Petersen nail or three nails or two screws or whatever agent of internal fixation appeals to one. It is necessary to work hard to do a lot of study and exercise great care if one is going to do work of this kind and have success. The work that my associates and I have presented is perhaps not the final solution, but certainly internal fixation is the best method available at the present time.

## INTRAVENOUS ALIMENTATION

WITH SPECIAL REFERENCE TO PROTEIN  
(AMINO ACID) METABOLISM

ROBERT ELMAN, M.D.

AND

D. O. WEINER, M.D.

ST. LOUIS

Intravenous (as a method of parenteral) alimentation becomes important whenever the nutritional needs of the body cannot be met by oral feeding; it becomes essential when death threatens because of nutritional deficiencies which can be remedied in no other way. These nutritional needs comprise six elements: water, salts, carbohydrate, protein, fat and vitamins. As far as water, salts and carbohydrate are concerned, intravenous alimentation is now a commonplace and extensively used procedure. For example, at the Barnes Hospital 125 liters and at the St. Louis City Hospital 200 liters of saline and dextrose solutions for subcutaneous and intravenous administration are used daily. Why have the remaining three nutritional elements been overlooked? If carbohydrate is important, why not protein, fat and vitamins? The answer lies partly in lack of information on the real needs for protein, fat and vitamins in patients more or less completely, though temporarily, unable to ingest any food by mouth. Another probable reason is the chemical complexity of these nutritional elements, which makes it difficult to prepare them for parenteral use. Fat, it is true, has been prepared in a fine emulsion for intravenous injection.<sup>1</sup> It is questionable, though, whether fat is really essential for maintenance, at least for short periods. Even for growth, fat has been shown to be dispensable, at least if one unsaturated fatty acid, linoleic acid, is provided.<sup>2</sup> It would seem that the other lipids can be manufactured from carbohydrate and protein. Vitamins, to be sure, are rapidly being isolated in pure form and several (B<sub>1</sub>, B<sub>2</sub>, C and nicotinic acid) can now be given intravenously. How important are they, however, for relatively short periods of nutritional deficiency? Since many of the vitamins are stored in the liver and elsewhere, these accessory food factors may perhaps be disregarded, unless of course prolonged parenteral alimentation becomes necessary. It must be admitted nevertheless, that with certain sick patients the need for one or more vitamins may be an important part of their nutritional needs. We shall be more concerned in this paper with the need for protein; it should be emphasized, however, that it is difficult if not impossible to consider one element independently, since each is closely related to the others in its metabolic behavior.

### INDICATIONS FOR INTRAVENOUS ALIMENTATION

In the case of water and salts the indications for parenteral administration are well known; they are most urgent when much water and salts are lost, for example in anhydremia (dehydration) from whatever

cause. Serious symptoms may rapidly develop and death may ensue unless water and salts are given. Since some disease usually prevents oral assimilation, the essential water and salts must be given intravenously. If this is promptly done a rapid improvement in the clinical condition occurs, accompanied by a return of the chemical composition of the blood to normal.

The common indications for parenteral carbohydrate alimentation are likewise generally accepted. But what of the need for protein? As will be mentioned in more detail subsequently, this need should be discussed in terms of amino acid or nitrogen metabolism. Thus nitrogen in the form of amino acids is constantly needed to form new proteins, to take care of the wear and tear of tissue and for other purposes, even when abundant calories are supplied. Since there are great stores of protein in the muscle (and elsewhere) it has been generally assumed that, as long as calories are supplied, one need not be concerned about the need for nitrogen. The supposition has been that muscle, being a relatively nonvital tissue, can easily be spared to supply by hydrolysis the amino acids necessary for nitrogen metabolism even for long periods.

One of the first evidences that muscle or other nonvital protein stores become inadequate during protein starvation was the observation of hypoproteinemia, which often results in nutritional edema. Since serum protein becomes depleted it is inevitable that other sources of protein are similarly affected and that muscle therefore is not the only tissue which is being autolyzed. It then becomes important to know what clinical manifestations are produced when, for example, the liver protein reaches a low level. What occurs when the various endocrine glands and the cardiac muscle find their protein drawn on? These questions cannot be answered until more careful study is made of patients suffering from protein starvation. It seems obvious, at any rate, that the skeletal muscle and liver (or any other more theoretical store of body protein) cannot always be depended on to satisfy nitrogen metabolism and that therefore the indications for parenteral protein alimentation are to that extent the same as those for carbohydrate. Briefly, they comprise conditions under which oral alimentation becomes defective or is contraindicated.

Oral alimentation fails in many circumstances besides the well known ones, e. g. when intestinal obstruction or repeated vomiting makes feeding impossible. Thus in cases of general peritonitis food can be given by mouth but only with deleterious results, even when vomiting does not occur. In cases of intestinal fistula or severe ulcerative colitis with diarrhea, food given by mouth may be either insufficiently digested or excreted before sufficient absorption can occur. Moreover, the hypermotility produced by the ingestion of food is said to be followed by an excessive loss of nitrogen in the urine and feces in many such cases. Intravenous alimentation not only supplies missing nutritional elements but permits the intestinal tract to be put completely at rest, a beneficial prerequisite to healing in many cases, especially when surgical procedures are necessary.

Perhaps the most clearcut indication for parenteral protein alimentation is the nutritional edema already mentioned, occurring because of hypoproteinemia. Especially important is the fact that the edema may involve the intestinal mucosa, interfere with absorption of food and lead to a vicious circle. In the past such

intestinal edema was probably present at the stoma in many cases of pyloric obstruction in which obstructive signs persisted even after an adequate passage was produced by gastro-enterostomy. This proved puzzling to the surgeon and often led to further and useless operations. Recent studies, especially the experiments of Mecray, Barden and Ravdin,<sup>3</sup> have shown in fact that with the relief of hypoproteinemia both the edema and the obstructive manifestations disappear. Some type of parenteral protein alimentation is obviously essential in such cases, at least for a short time, in order to break the vicious circle, transfusions have been especially recommended in order to bring the serum protein content to normal.

Plasma as a source of intravenous protein alimentation can maintain nitrogen balance, this has been demonstrated experimentally.<sup>4</sup> As a source of nitrogenous nourishment it has certain practical drawbacks. Thus it would be necessary to give two 500 cc transfusions a day in order to introduce 35 Gm of serum protein, an amount which is certainly at the lower level of the protein needs of a 70 Kg adult. Since the red cells are not needed, plasma should be separated from whole blood and given alone. A more serious defect in the use of plasma as a source of nitrogen nutrition is the fact that it supplies only one of the protein needs, i. e., the need for serum protein. In order to supply other tissues the protein must be first hydrolyzed by the body to amino acids, which then circulate in the blood and supply the various tissues, as illustrated in the accompanying chart. In a very sick patient this process may occur too slowly or perhaps not at all. This may be the reason that a transfusion for severe nutritional edema is sometimes ineffective (cases 2 and 8).

The indications for intravenous alimentation, finally, may become extended as more is learned about the various defects which occur in intestinal absorption. One example, due to hypoproteinemia, has already been mentioned. Recent observations by Groen<sup>5</sup> have shown a diminished intestinal absorption of dextrose in various deficiency diseases. Protein has many more hurdles to hop before it becomes available to the tissues. If digestion is defective or if absorption is impaired, an adequate supply of amino acids may not reach the tissues. The element of time may also be important, evidence will be presented subsequently<sup>6a</sup> suggesting that unless all the essential amino acids are present in the tissues at the same time synthesis may be impaired.

#### AMINO ACIDS FOR INTRAVENOUS PROTEIN ALIMENTATION

Protein as a source of parenteral alimentation can be given only in the form of amino acids, aside of course from the use of matched blood in a transfusion (or plasma alone), which has already been discussed. Amino acids represent the form in which protein food enters the blood stream from the intestinal tract after appropriate digestion and absorption, thus it has become customary to speak of the use of protein in terms of amino acid metabolism. Indeed, one may even speak of protein and amino acids in terms of nitrogen metab-

olism, as nitrogen metabolism can be maintained by the administration of an adequate supply of protein or amino acids of the right sort. Since amino acids in general are soluble and nontoxic (in ordinary amounts) they should be just as suitable for intravenous injection as dextrose.

Of the twenty-one or more amino acids which make up the usual protein foods, only nine (possibly ten) are essential<sup>6</sup>. Thus by supplying an adequate amount of these nine amino acids the nitrogenous needs of the body should be met. This has been done<sup>7</sup> for growing rats, undoubtedly it would also suffice for the less rigorous needs of maintenance. From the practical point of view, however, such an approach is unfeasible because of the high cost of pure amino acids. A much more economical method is to hydrolyze

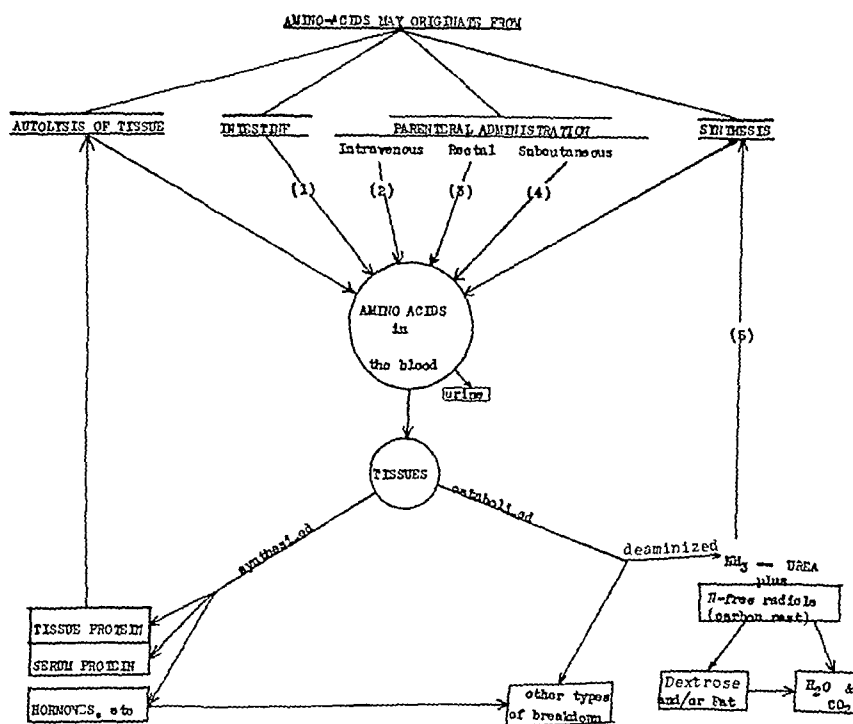

protein after hydrolysis would have the same composition. Quantitative analysis of the amino acids in such a mixture would be valuable in revealing its deficiencies, but it is hampered at present by the lack of satisfactory methods for the estimation of all the amino acids. For these reasons a simpler approach is to test the biologic maintenance value of a particular mixture of amino acids by direct experiment. One method is based on studies of nitrogen balance, another is based on the regeneration of serum protein, the only bodily protein which can be more or less readily and directly measured. Both methods were used in the present observations.

Previous observations on parenteral alimentation with amino acids are few, aside from the many experiments in which single injections were made for chemical studies, such as those of Van Slyke and Meyer,<sup>8</sup> who injected protein hydrolysates into anesthetized dogs and studied the distribution of the amino acids several hours later. Henrique and Andersen<sup>9</sup> carried out intravenous alimentation for one month on a single goat, they used digested meats as their source of nitrogen. The animal remained in nitrogen balance and gained weight. Rectal alimentation with hydrolyzed protein was described by Abderhalden, Frank and Schittenhelm<sup>10</sup> and later by Griesbach<sup>11</sup>. Their patients showed definite evidence of utilization. The cases herein reported are believed to be the first in which hydrolyzed protein has been injected intravenously into human beings.

#### EXPERIMENTAL OBSERVATIONS

The amino acids used in all the studies herein described were obtained from the acid hydrolysis of casein<sup>12</sup>. All the essential amino acids of casein were presumably present except tryptophan, which is destroyed during the hydrolysis. To make the mixture complete 2 per cent of this essential amino acid was added. Under these conditions the product supported normal growth in rats<sup>13</sup>. In many of our experiments 2 per cent of cystine (or methionine) was also added because of the low concentration of cystine in casein. The basic product (hereinafter called the incom-

plete mixture) without the added amino acids served excellently as a control in many experiments. Adult dogs were used exclusively. Chemical determinations were carefully checked by frequent duplicate analyses. In most experiments a macro-Kjeldahl method was used in determining nitrogen, in some, however, nesslerization was employed.

Probable paths involved in protein and amino acid metabolism. It should be noted that tissue protein and serum protein are not interchangeable directly; they must first be autolyzed and their amino acid constituents made available by the blood stream for synthesis by other tissues or cells. The numbers refer to the following considerations: 1. The amino acids from digested protein in the intestine are absorbed and enter the portal system slowly and at various rates and they reach the liver before the muscle. 2. In contrast by the intravenous route all amino acids reach the tissues at the same time; the liver receives them simultaneously with the muscle. 3. Rectal alimentation is subject to the vagaries of colonic absorption which apparently varies considerably. 4. Subcutaneous alimentation requires large volumes of solution since isotonicity must be maintained when edema is present absorption may be delayed. 5. This mode of amino acid synthesis is based partly on theoretical considerations; it probably occurs at least as far as the simpler amino acids are concerned by a combination of ammonia and lactic acid or pyruvic acid (Sherman H. C. *Chemistry of Food and Nutrition*, ed. 5, New York: Macmillan Company, 1937, pp. 223-224).

a relative pure protein until it is broken down into its constituent amino acids. If the protein selected contains all the essential amino acids in adequate proportions, the resulting product should be suitable, provided of course that none of the essential constituents are destroyed during the process. Obviously also such a hydrolysate must prove entirely nontoxic when given intravenously in ordinary amounts. Although Rose has determined the ideal formula of essential amino acids for growth,<sup>7</sup> it is unlikely that any easily available

6. Most of our recent knowledge of the nutritive significance of amino acids has been contributed by the extensive researches of W. C. Rose and his collaborators. Much of this data as well as an able review of the literature can be found in two recent papers by this author (*Science* 86: 298 [Oct. 1] 1937; *Physiol. Rev.* 18: 109 [Jan.] 1938).

13. Kemmerer H. S. Personal communication to the authors.

Preliminary studies showed that the product was not anaphylactogenic for guinea pigs. By either the Folin colorimetric or the Van Slyke titrimetric method, 95 per cent of its nitrogen was in the form of amino acids. The product was easily soluble as a 10 per cent solution which was acid in reaction ( $pH$  5 to 6) and amber in color. An equal concentration of dextrose was always added not only because of its caloric value but also because there is considerable evidence that the utilization of amino acids is enhanced by the presence of carbohydrate. The rate of intravenous injection was important, a 10 Kg dog was likely to retch or vomit (sometimes with diarrhea) if more than 100 Mg of amino acids a minute or 6 Gm an hour was given, and considerable amounts of amino acids might be lost in the urine. However, this rate is very high, in most experiments only about 1 Gm of amino acids was injected an hour. Regardless of the rate of injection, it was found that the amino acids left the blood stream with great speed after even large intravenous doses.<sup>14</sup> In order to determine whether they were utilized, two types of experiment were carried out.

**Studies of Nitrogen Balance**—When amino acids enter the blood stream they are subject to three possible effects, as shown in the accompanying chart. They may be excreted in the urine as such, they may be deaminized (or broken down in other ways) and measured in the urine as nitrogen (largely urea and ammonia), they may be retained and synthesized. The first possibility was avoided by a slow rate of injection. Whether retention occurred was then evident by study of the nitrogen excretion. Such balance experiments showed that almost complete retention of the amino acid nitrogen occurred whenever the complete mixture of amino acids was injected, under these conditions immediate nitrogen balance was achieved. Such retention of nitrogen is supposed to mean actual synthesis. Ordinarily this assumption may not be justified because of the possibility that the retained amino acids may be simply stored as such and not synthesized into protein. For this reason a control experiment was carried out with the incomplete mixture of amino acids (tryptophan and cystine were not added). If the hydrolyzed casein was retained as such, the retention should have occurred whether or not a few milligrams of tryptophane and cystine was added. Yet in each experiment with the incomplete mixture, very slight retention occurred. Moreover, under such circumstances nitrogen balance was not achieved. The details of these experiments have been described elsewhere.<sup>15</sup>

In further experiments with the incomplete mixture of amino acids it was found that nitrogen balance was not achieved if the missing essential amino acids (tryptophan and cystine) were injected separately eight hours after the injection of the basic mixture.<sup>16</sup> It seemed therefore that retention and utilization of a mixture of amino acids required not only all the essential amino acids but that they be present at the same time. Thus when an incomplete mixture is injected, apparently deamination occurs rapidly and, if the missing essential amino acids appear on the scene too late, retention (and synthesis) do not occur. This phenomenon if confirmed would explain the relative superiority of intravenous over oral alimentation of protein when

intestinal function is defective, since in this case delays in absorption of essential amino acids may lead to excessive loss of nitrogen by deamination. Peters and Van Slyke<sup>17</sup> have discussed observations showing that deamination occurs soon after ingestion of protein, destruction of amino acids apparently does not wait until all the protein has been digested and absorbed. The present observations confirm this theory. Further observations are being made of this interesting phenomenon.

**Regeneration of Serum Protein**—There are many experiments recorded in the literature on the regeneration of serum protein reduced either by repeated plasmapheresis or by a long-continued nonprotein diet. In the present experiments a simpler and shorter procedure was used. In fasting dogs a reduction in serum protein was produced by a severe hemorrhage. In the controls no regeneration occurred in six hours and but little in twenty-four hours. If amino acids were injected intravenously, however, definite evidence of an increase in serum protein was obtained within six hours. These experiments have been described elsewhere.<sup>17</sup>

In another series of observations hypoproteinemia was produced by a nonprotein diet similar to that described by Weech, Goettsch, and Reeves.<sup>18</sup> In many of the dogs obvious nutritional edema appeared, they all showed a fall in the level of serum protein, usually within a few weeks. After the intravenous injection of a complete mixture of amino acids there was striking diminution of the edema, often within a few hours and always in twenty-four hours. The serum protein changes were far less striking. Nevertheless, in several experiments definite alleviation of the hypoproteinemia was achieved as compared with controls in which an incomplete mixture was used.

**Histologic Studies**—All dogs receiving amino acids intravenously were eventually examined post mortem. The liver and kidneys in no case showed any evidence of change referable to the injected amino acids, even when large or long-repeated doses had been given.

#### CLINICAL OBSERVATIONS

Our first concern in giving hydrolyzed casein to patients was, of course, the possibility of untoward reactions, even though none had occurred in dogs. At first small doses were injected, they produced no demonstrable effect, so that eventually we administered what was thought to be a full daily quota of amino acids, i. e., from 0.5 to 2 Gm per kilogram of body weight.

The hydrolyzed casein was generally made up as a 10 per cent solution and tryptophan and methionine (or cystine) added. It was then passed through a sterile Seitz filter and poured directly into 5 or 10 per cent dextrose solution as ordinarily prepared for routine use. In this way sterility was achieved without the danger of breaking up any of the amino acids through autoclaving. Usually each liter contained about 20 Gm of amino acids to 80 Gm of dextrose. If given slowly over the course of at least two hours the 20 Gm of amino acids did not spill over into the urine and produced no objective reaction, there was no elevation

of temperature or pulse rate. Subjectively some patients noticed a sense of warmth, which was evident in a slight peripheral vasodilatation. One patient stated that he felt slightly chilly, but no chill occurred and the temperature remained normal, one child had a transient rash after one injection and vomited once.

About a score of patients were given amino acids intravenously, but to only eight were large amounts given for more than one or two days, their clinical summaries are given later. Complete chemical measurements were not carried out in many cases, so that the observations herein recorded are presented as preliminary studies. The results have been sufficiently promising to justify the hope that further use will produce added evidence that this method of alimentation not only is harmless but results in active and rapid synthesis of tissue and other protein. Both Kjeldahl and nesslerization methods were used in the determination of nitrogen. The albumin and globulin portions of serum were separated by Howe's method.

#### REPORT OF CASES

CASE 1—W C, a man aged 55, a patient at the St. Louis City Hospital, had an extensive inoperable carcinoma of the stomach, with complete obstruction at the cardia, so that he could ingest no nourishment and was rapidly deteriorating in spite of intravenous and subcutaneous administration of dextrose and saline solutions. For one month he received continuous venoclysis, consisting each day of 4,000 cc of 10 per cent dextrose containing 20 Gm of hydrolyzed casein with added tryptophan and cystine and 750 cc of physiologic solution of sodium chloride. No reaction occurred and no subjective manifestations were apparent, the general condition, which was rapidly going downhill, was improved so that the patient seemed stronger and was able to read and smoke. The nitrogen output in the urine varied between 3 and 4 Gm a day. Nitrogen balance was achieved whenever the dose of amino acids was increased to a point above this level. However, if tryptophan and cystine were omitted from the mixture the output of urinary nitrogen rose to 5 and 6 Gm a day. The serum protein content at the beginning of the experiment was 4.31 Gm per hundred cubic centimeters and at the end 5.52 Gm, this increase was mostly in the albumin fraction, which rose from 2.35 to 3.16 Gm per hundred cubic centimeters. That this increase was probably not due to concentration (decrease of plasma volume) was suggested by the red cell count, which remained at about 3,000,000 during the entire period.

CASE 2—I H, a man aged 51, a patient at the St. Louis City Hospital, after resection of the intestine for volvulus two months before had had a stormy course. When first seen he was emaciated and exhibited a pronounced nutritional edema in spite of fifteen transfusions. Although enterostomy had produced a functioning opening, frequent stools were passed, food was eaten, but obviously little if any was assimilated. The serum protein content was 3.54 Gm per hundred cubic centimeters, equally divided between albumin and globulin. On two successive days 500 cc of blood was given without affecting the edema. A reaction followed one of the transfusions. Acacia was also given without effect. Nov. 16, 1937, 20 Gm of amino acids was given in 750 cc of 10 per cent dextrose solution without reaction. The following day the edema was definitely better, and 3,000 cc of urine had been excreted, the patient stated that he felt better. There was no immediate change in the serum protein. On other occasions transfusions of whole blood as well as of plasma alone were given to this patient without influencing the edema, each time amino acids were injected a reduction of edema occurred. The serum protein value eventually rose to 5.01 Gm per hundred cubic centimeters but fell again on cessation of intravenous alimentation, which finally became impossible because of thrombosis of the existing veins. The patient, who at all times was on the verge of nutritional collapse, finally died of pneumonia. It was felt

that a shorter and more intensive regimen of dextrose and amino acids alone might have saved his life.

The influence of rapid changes in plasma volume on the concentration of serum protein was observed several times in this patient. On one morning the serum protein content was 4.29 Gm per hundred cubic centimeters, in the evening, after intravenous administration of fluid, it was 3.11 Gm, that this was due largely to dilution of the blood was shown by a fall in the hematocrit reading (cell volume) from 48 to 40 per cent and of the red cell count from 5.5 to 4.5 million. On another occasion the serum protein content fell from 4.06 to 3.51 Gm after administration of fluids. Also the hematocrit reading (cell volume) fell from 50 to 40 per cent and the red cell count from 5.18 to 4.4 million.

CASE 3—R B, a woman aged 67, a patient at the St. Louis City Hospital, had an inoperable carcinoma of the stomach and could take nothing by mouth. Intravenous alimentation with dextrose and saline solutions was carried out until the urinary output of nitrogen reached a level of about 4 Gm a day. On three successive days 4.5 Gm of nitrogen as amino acids was added to the dextrose solution, only slightly increasing the output of nitrogen. It was concluded that almost complete retention of the injected amino acids occurred. No reaction whatever accompanied this experiment.

CASE 4—W W, a man aged 75, a patient at the St. Louis City Hospital, had an obstructing carcinoma of the esophagus but refused gastrostomy and agreed to intravenous alimentation. The nitrogen output of the urine was measured daily. When the complete mixture of amino acids with dextrose was injected, little change in nitrogen output occurred and the patient achieved nitrogen balance at once. When the incomplete mixture was used, a large increase in urinary nitrogen appeared, thus confirming for human beings the observations already mentioned for dogs. No reaction was observed after the injections. This patient showed wide variations in the concentration of serum protein, often but not always explainable by changes in plasma volume as revealed by the hematocrit.

CASE 5—N O, a woman aged 69, a patient at the St. Louis City Hospital, had severe septicemia and was comatose for most of her clinical course until she died. Because nutritional edema with hypoproteinemia developed, amino acids were added for three days to the intravenous drip of dextrose and saline solutions. The urinary output of nitrogen was level at about 4 Gm a day. Although the daily quota of injected nitrogen as amino acids was 5.16 Gm, the urinary nitrogen increased only to 4.5 Gm indicating achievement of a definitely positive nitrogen balance. The serum protein content increased from 4.89 to 6.06 Gm during this period, while the hematocrit reading remained unchanged.

CASE 6—R P, a boy aged 8 months, a patient at the St. Louis Children's Hospital, who was in the hospital for two months before he died, entered with an infection of the upper part of the respiratory tract which required myringotomy and eventually bilateral mastoid antrostomy. There then developed severe persistent dysentery (Hiss-Russell), which failed to respond to any form of therapy. Many transfusions were given. The general condition grew steadily worse, and his weight fell from 6,200 to less than 4,500 Gm. At autopsy the only abnormality found was pronounced shaggy ulcerative colitis involving the entire colon.

At the suggestion of Dr. A. F. Hartmann a continuous intravenous drip was instituted, this was done during the most critical period of the baby's illness. For ten days 50 Gm of dextrose and 10 Gm of amino acids in 500 cc of half strength Ringer's solution was given daily. Under this regimen the clinical condition of the baby improved, and the stools became less frequent and more nearly normal. Eventually all the veins were used and no further venoclysis was possible. There was no evidence of reaction during the period of intravenous alimentation. Chemical studies of the blood showed a surprising fall in the concentration of serum protein from 4.76 to 3.53 Gm per hundred cubic centimeters. However, the hematocrit reading (cell volume) fell even more, i. e., from 44 to 22 per cent indicating a rise in the relative plasma volume and therefore an increase rather than a decrease in the total plasma

protein The baby showed no edema in spite of the hypoproteinemia Death occurred suddenly several days after the intravenous therapy had ended

It is of interest to note that although this baby received over 2 Gm of amino acids per kilogram of body weight a day for ten days, histologic study of the liver, kidney and spleen at autopsy revealed no changes

CASE 7—J C, a boy aged 2 years, a patient at the St. Louis Children's Hospital, had chronic nephrosis with hypoproteinemia and edema At the suggestion of Dr A F Hartmann he was given intravenously each day for three days 15 Gm of amino acids and 35 Gm of dextrose in 350 cc of Ringer's solution, divided in two equal doses, each injection lasting two hours There was no reaction except that on the third day a transient macular rash developed and he vomited once Study of the serum protein showed a slight increase from 3.92 to 4.51 Gm per hundred cubic centimeters, largely due to the albumin fraction, which increased from 1.5 to 1.88 Gm The hematocrit reading (cell volume) during this period changed but little (34 to 36 per cent)

CASE 8—C T, a man aged 67, a patient at the Barnes Hospital was seen in consultation with Dr N A Womack, who suggested the use of amino acids He was already emaciated when enterostomy was performed for intestinal obstruction After operation severe nutritional edema developed The serum protein content was first 4.9 Gm per hundred cubic centimeters, in spite of a transfusion one week later it had fallen to 3.4 Gm There was no corresponding change in the red cell count Acacia was also used, but the edema increased and the general condition grew worse, vomiting and distention developed, requiring continuous gastric suction Hypertonic sucrose solution was also used without apparent effect Twice each day he had been receiving 1,000 cc of 10 per cent dextrose intravenously on four successive days amino acids were added to the dextrose, so that he received 40 Gm of the hydrolyzed casein daily (the patient's weight was estimated at 40 Kg) No reaction occurred the only subjective sensation being a sense of warmth during the injection and once a feeling of momentary chilliness afterward Twenty-four hours after the start of the injections a definite decrease in the edema was obvious, this improvement continued until the edema was entirely gone several days later Vomiting ceased, and the patient started to eat There was definite diuresis much fluid was also lost through the enterostomy opening The general condition improved, and bowel movements soon appeared by rectum The serum protein content rose to 3.9 and then to 4.7 Gm per hundred cubic centimeters several days after cessation of the intravenous therapy The red cell count remained constant at about 3.9 million, suggesting that there was no change in relative plasma volume

All patients coming to autopsy were especially examined for any parenchymatous changes in the liver or kidney which might be indicative of a toxic effect of the injected amino acids No such evidence was found This was especially significant in case 6 in which over 2 Gm per kilogram a day had been given for ten consecutive days

#### COMMENT

Only a few of the many aspects of intravenous alimentation have been considered in the present paper The observations recorded, however, seem to indicate that the nitrogen needs of the body can be supplied by the intravenous administration of an appropriate mixture of amino acids Such a mixture can be prepared by the acid hydrolysis of casein, it was given intravenously to dogs and to human beings with no evidence of toxic reaction either clinically or anatomically Unfortunately such a product lacks tryptophan which must be added before the mixture will support nitrogen metabolism, this is an important defect from the practical point of view because tryptophan is one of the most

expensive of the many amino acids Other preparations of hydrolyzed protein are now being studied It is probable that a complete as well as inexpensive mixture will soon become available for clinical trial

The experimental and clinical results herein presented constitute definite evidence that the injected amino acids are actually utilized by the body to supply its nitrogen needs Much of this evidence consists of observations on nitrogen balance Although these studies involve the assumption that retention of the injected amino acids means synthesis, control experiments tended to justify this assumption The most dramatic effect of the injection of amino acids occurred in the relief of nutritional edema and in the apparent improvement in the general condition of several very sick patients There was, it is true, an occasional failure to correlate these clinical effects with a prompt elevation of the serum protein content It should be stated, however, that in many studies of hypoproteinemia by others considerable lag has been noted between the appearance (and disappearance) of nutritional edema and the changes in the serum protein This lack of exact parallelism between serum protein concentration and nutritional edema may be due to other factors which influence edema, retention of salt immediately comes to mind In the present study salt edema was not present One must also consider the effect of rapid changes in the plasma volume on the serum protein concentration, which is especially shown in case 2 On the other hand, when a rapid fall in serum protein content was produced by a severe hemorrhage, definite evidence of regeneration was observed to follow rapidly the administration of amino acids<sup>17</sup>

With regard to the quantity of dextrose and amino acids needed for intravenous alimentation, a rough estimate should be made For a 70 Kg adult certainly 1,600 calories should be given, and more if fever is present Thus at least 400 Gm of dextrose and amino acids should be injected Of the latter, sufficient should be given to keep the patient in positive nitrogen balance From the various statements in the literature at least 0.5 Gm per kilogram should be adequate In the adult patients observed by us in which the excretion of nitrogen was studied for a long period, 5 Gm a day was the usual maximum output This corresponds to an amino acid intake of over 30 Gm, which is just about the 0.5 Gm per kilogram just mentioned In other patients the nitrogen needs are probably much greater Ringer's solution meets the need for electrolyte, though a note of warning should be uttered with regard to the danger of giving too much salt Ordinarily from 7 to 10 Gm of sodium chloride a day should be sufficient If this amount is exceeded, the kidneys may not be able to excrete all of it and retention of salt may follow, this salt may gather in the tissues and rapidly produce a salt edema One liter of physiologic solution of sodium chloride (or Ringer's solution) is usually ample, except of course in the case of anhydremia, when much more is required at the beginning at least to relieve the hypochloremia

The remaining requirements for complete intravenous alimentation, namely vitamins and fat, obviously call for extensive study Doubtless in a few patients utilization of dextrose and amino acids is impaired because of missing vitamins These accessory food factors are much more than antidisease substances, their primary effects are metabolic and are even now being carefully

studied by many workers. It may be that most patients in whom intravenous alimentation is indicated do not have significant vitamin deficiency, so that for them the injection of these food factors is not needed. As for fat, it seems likely that for maintenance it may be dispensed with. On the other hand, from the practical point of view fat has a great advantage in parenteral alimentation. The mechanical problem of injecting enough calories would be simplified by the availability of fat, since it produces two and one-half times as many calories per gram as dextrose or amino acids.

## SUMMARY

For the first time, it is believed, a mixture of amino acids has been given intravenously to human beings for parenteral protein alimentation. The mixture was obtained by the acid hydrolysis of casein to which was added 2 per cent tryptophan and cystine (or methionine). No evidence of toxicity either clinically or histologically was observed when the injection was given slowly, even though as much as 2 Gm per kilogram a day was injected. Experimental and clinical observations have indicated that the injected amino acids are rapidly utilized, this was shown by nitrogen balance studies, by regeneration of serum protein and by reduction of nutritional edema.

## ABSTRACT OF DISCUSSION

DR THEODORE L. ALTHAUSEN, San Francisco. I didn't intend to discuss the work of Drs. Elman and Weiner, but a paper which offers something new should not go without discussion. After intravenous administration of dextrose came into general use, various investigators began to cast about for means of similarly administering fats and proteins, especially in cases in which parenteral alimentation has to be carried on for longer periods. Dr. Emmett Holt Jr. devised a successful method of administering intravenously emulsions of fat to children. Another investigator has experimentally used protein hydrolysates for nutrient enemata with apparent success. The authors are the first to come out officially with their work in the field of parenteral administration of amino acids. From my own work I am very much interested in the important part which dextrose plays in the metabolism of fats and in practical application of this, for instance in the treatment of ketosis. It was interesting to hear that dextrose is also necessary for the utilization of amino acids.

DR THOMAS T. MACKIE, New York. The development of a nutritionally complete diet which may be administered intravenously would constitute an exceedingly important contribution to the therapy of many conditions. Present limitations of parenteral and intrarectal feeding inevitably induce malnutrition if continued for more than brief periods. This in its turn implies an added hazard to the patient. If further studies confirm the authors' preliminary results this work may constitute one of the most important contributions to therapy of recent years.

**Servetus**—It was in 1546 that Servetus discovered the lesser circulation of the blood. Cesalpinus (1524-1603) discovered the greater circulation in 1569, and Sylvius (1478-1555) and Fabricius of Aquapendente (1537-1619) discovered the valves in the veins before 1574 thus antedating even the birth of Harvey by four years. Servetus, in his book on the Trinity, had fearlessly announced that Galen was wrong in his ideas of the circulation of the blood. He showed for the first time that there was no communication between the two sides of the heart, and that the blood flowed from its right side to the lungs, and returned to its left side to be sent to all parts of the body. Harvey, who somewhat later studied in Italy and France, also knew these facts but he dared not publish them in England during the reign of his kings, James I and Charles I.—Hurd-Mead, Kate Campbell. *A History of Women in Medicine*, Haddam Press 1938.

CHRONIC ADHESIVE SPINAL  
ARACHNOIDITIS

## A CLINICAL AND PATHOLOGIC STUDY

ROLAND P. MACKAY, M.D.

CHICAGO

Chronic fibrotic or adhesive changes in the spinal arachnoid have been described for more than forty years. Designated as meningitis, or more often as arachnoiditis, these changes have been characterized as serous, fibrous, adhesive or cystic and as diffuse, disseminated or circumscribed. The first report was that of Schwarz,<sup>1</sup> who in 1897 described the clinical and pathologic features in a case supposedly of syphilitic origin, with sclerotic and cystic meninges and focal areas of softening and cavitation in the spinal cord. Schwarz's article is one of the few containing detailed pathologic descriptions and has never received the attention it deserves. Circumscribed cysts of the arachnoid are especially apt to simulate tumors, as shown in the first report from America, in 1903, by Spiller. Numerous later reports, such as those by Horsley, Munro,<sup>8</sup> Schuster,<sup>7</sup> Mauss and Kruger,<sup>6</sup> Stookey, Barre,<sup>9</sup> Elkington,<sup>9</sup> and Selmsky<sup>10</sup> and particularly the extensive monographs by Metzger<sup>11</sup> and Paulian and Turnesco,<sup>12</sup> contributed to our clinical knowledge of the various types of spinal arachnoiditis without, however, completely solving the diagnostic difficulty. Even today the condition is rarely differentiated preoperatively from cord tumor if a manometric block is present and if a block is absent the disease is often missed entirely and left buried in such doubtful clinical categories as "lateral sclerosis" or "paraplegic multiple sclerosis." In some cases it is mistaken for subacute combined degeneration of the cord and in others for amyotrophic lateral sclerosis.

The pathologic characteristics of spinal arachnoiditis have been described by a few workers, but chiefly with regard to the state of the arachnoid rather than the cord. Schwarz's report,<sup>1</sup> the first is one of the best. Horsley<sup>3</sup> gave brief descriptions of the gross changes, pointing out the tendency toward degeneration of the white matter around the margins of the spinal cord underlying the pia. The pathologic studies of Schuster,<sup>7</sup>

From the Research and Educational Hospital of the University of Illinois and St. Luke's Hospital.

Geistmann,<sup>13</sup> Bonhoeffer,<sup>14</sup> Pette,<sup>15</sup> Harbitz and Lossius,<sup>16</sup> Brouwer,<sup>17</sup> Maimesco and his associates<sup>18</sup> and Yasuda<sup>19</sup> have added much to our knowledge of the alterations in the spinal cord. None of this pathologic study on the cord has been done in America, and little of the literature is available in English. Grinker's<sup>20</sup> observations were made in a case in which the spinal cord was largely spared.

#### ARACHNOIDITIS FOLLOWING ACUTE MENINGITIS

**CASE 1—***Acute (meningococcic?) meningitis followed after five weeks by generalized pains paraplegia with muscular twitching, painful spasms and atrophy, unequal reflexes, extensor plantar responses and subarachnoid spinal block, operation, death, chronic adhesive arachnoiditis with extensive focal softening of the cord.*

**History and Examination—**L. S., an unmarried white man aged 24, a laborer, was admitted to the service of Dr. LeRoy Sloan at the Illinois Central Hospital, Chicago, Sept. 28, 1934. Three years previously an attack of acute otitis media had subsided after paracentesis. Beginning August 15 he was critically ill for five weeks with a purulent form of meningitis in which no organism could be identified in the small hospital where he was a patient. Treatment included only symptomatic measures and frequent spinal punctures. Although his general condition improved, weakness of the lower extremities with urinary incontinence appeared soon and grew progressively worse. Headache persisted and pains appeared in the neck, back and legs with transient attacks of 'numbness' in the arms.

Examination on admission in the sixth week of illness revealed extreme flaccid weakness of the lower extremities including the flexors of the hips. Gross fascicular muscle twitches were seen in the thighs and calves. Superficial sensibility was normal except for a small perianal area of hypesthesia and somewhat delayed responses below the umbilicus. Vibration and position sense was abolished in the lower extremities. In the right leg the tendon reflexes were exaggerated; in the left the patellar and internal hamstring reflexes were absent, while the Achilles and external hamstring reflexes were reduced. The abdominal reflexes were normal, but the Babinski response was strong on both sides. There was urinary and fecal incontinence.

Lumbar puncture produced only one drop of yellow viscid fluid, but cisternal puncture revealed normal fluid with normal dynamic responses. Iodized oil introduced into the cisterna magna was arrested in irregular masses scattered between the first and fourth cervical vertebrae. Roentgen examination of the mastoids and lungs gave negative results, the sputum contained numerous leukocytes and pneumococci, Wassermann and Kahn tests of the blood and cisternal fluid were negative. The urine was normal except for many erythrocytes, a few leukocytes and a trace of albumin.

**Course—**The patient's temperature and pulse remained normal, but headache and pains in the neck, back and extremities persisted. Gradually some weakness appeared in the arms and a small decubitus ulcer over the sacrum.

**Operation—**At St. Luke's Hospital, October 23, Dr. Eric Oldberg performed a midcervical laminectomy and found a greatly thickened dura and an exceedingly dense vascular

arachnoid membrane which was adherent to the cord. Some of the adhesions were broken up, the iodized oil was aspirated, and the wound was closed.

**Postoperative Course—**Troublesome headache and pains in the spine and extremities persisted. Motor weakness increased in all extremities, and painful muscle spasms began. Atrophy appeared in the shoulders, arms and legs and advanced slowly. Priapism and urinary and fecal incontinence were distressing. Superficial sensibility was but little disturbed but vibration and joint sense remained absent in the lower extremities. Death occurred December 3 of respiratory failure.

**Autopsy—**Postmortem examination, done in the department of Dr. H. Gideon Wells of the University of Chicago, revealed marked generalized emaciation, pressure necrosis over the sacrum, hemorrhagic cystitis with hypertrophy of the urinary bladder and multiple renal abscesses. There was also questionable early bronchopneumonia.

Gross examination of the nervous system disclosed a few meningeal adhesions over the base of the brain and diffuse meningeal fibrosis throughout the spinal canal. In the cervical and lumbar regions numerous small cystic cavities were found in the subarachnoid space, filled with a gelatinous substance, but in the thoracic region a simple dense fibrosis surrounded the cord.

Microscopically the meninges were the seat of a diffuse chronic inflammatory process, with infiltration by lymphocytes

Fig. 1 (case 1).—Fibrosis infiltration and cyst formation in the lepto meninges, secondary degeneration in the fasciculus gracilis, focal softening with demyelination especially in the periphery of the white matter and degeneration of the gray substance with cavitation. Weigert-Pal stain counterstained with van Gieson stain, reduced from a photomicrograph with a magnification of 8 diameters.

and plasma cells and marked collagenous fibrosis (fig. 1). No polymorphonuclear leukocytes or bacteria were found. These hyperplastic meninges were very vascular and the numerous vessels showed intimal and medial thickening, with occasional occlusion and hyalinization (fig. 2). Normal vessels were few. In many areas cystic cavities were found in the meshes of the fibrosed arachnoid, but none were large enough to have produced compression of the spinal cord. These cavities were lined by flattened or cuboidal epithelial cells, which were heaped up into several layers in some localities (fig. 3). Spinal nerve roots passing through these inflamed tissues were often remarkably free of changes, but some particularly dorsal roots, were definitely degenerating and exhibited hyperplasia of the endoneurium.

The spinal cord itself showed extensive changes. In Weigert-Pal preparations the dorsal columns exhibited secondary or Wallerian degeneration due to the destruction of the dorsal roots by the inflammation and sclerosis in the meninges (fig. 1). In the cervical segments this process was almost restricted to the fasciculus gracilis. Scarlet red stains showed great amounts of fat in this region, most of them lying free in the tissues

Moderate astrocytic gliosis was found in the dorsal columns, proportionate to the degree of degeneration.

The most striking changes in the spinal cord, however, were the focal areas of softening which occurred in both white and gray matter. In the myelin sheath stains, any portion of the white substance seemed liable to this focal destruction, but the marginal or subpial regions were especially affected (fig 1). In this manner the *randdegeneration* of the German observers was presented. Where necrosis was severe, all tissue elements had suffered, both parenchymatous and glial, and scarlet red stains revealed enormous amounts of fat lying free in the tissues. In the less acutely degenerated regions, there was reactive astrocytic gliosis. Numerous fat-granule (gitter) cells were found under the pia and about blood vessels.

In many areas the gray matter had undergone almost complete liquefaction with cavitation (fig 1). There was no tissue response, glial or collagenous, in such regions. In other locali-

Fig 2 (case 1)—Fibrosis and mononuclear infiltration in the leptomeninges; thickening of vascular walls with occlusion; status spongiosus in white matter. Weigert Pal and van Gieson stains slightly reduced from a photomicrograph with a magnification of 160 diameters.

ties the gray matter was less severely involved, but the ventral horn cells were sharply reduced in number. The remaining ganglion cells were deformed, shrunken and hyperchromatic, or swollen and chromatolytic, with eccentric, pale nuclei (fig 4). Such cells were studded with fat droplets when suitably stained. Satellitosis and neuronophagia were strikingly absent, however.

Blood vessel walls in the areas of focal necrosis were thickened in all three layers and the lumen sometimes obliterated. Round cell infiltration was occasionally seen about these vessels. Compensatory formation of new vessels led to increased vascularity throughout the whole cord.

Emphasis from a clinical standpoint in this case should be placed on the purulent, possibly meningococcic, meningitis, which gradually gave place to progressive paraplegia with widely disseminated "root pains," paresthesias, painful involuntary muscle spasms, eventually disseminated atrophy and loss of deep sensibility but relative preservation of superficial sensibility. The spinal subarachnoid block and characteristic arrest

of iodized oil at multiple levels clinched the diagnosis. The unsatisfactory surgical results were due to the impossibility of attacking so intense and diffuse a process. The most significant pathologic features were (1) the intense fibrosis and vascularization of the arachnoid with the formation of arachnoid cysts lined with epithelium, (2) the tendency to vascular thickening and occlusion in both the pia-arachnoid and spinal cord and (3) the focal softening of both the white and the gray matter of the cord. One cannot speak here of a myelitis secondary to the meningitis, since evidences of inflammation in the cord were practically absent. It was rather a gradual process of ischemic necrosis.

CASE 2—F. S., a white woman aged 45, experienced sudden and complete paraplegia in February 1935. There was a history of "influenza and meningitis" without spinal puncture in 1918, an illness from which she apparently recovered except for occasional back pains during the intervening sixteen years. Examination revealed paralysis with atrophy in the lower extremities and anesthesia below the first lumbar dermatome. The patellar reflexes were absent, the achilles exaggerated bilaterally. Spinal puncture revealed a complete block and 1,310 mg of total protein per hundred cubic centimeters of spinal fluid. Disregard of the history of meningitis led to a mistaken diagnosis of spinal cord tumor. At operation Dr. Eric Oldberg found an opaque, densely fibrotic and vascular arachnoid membrane which was impregnated with large calcified flakes (fig 5). Surgical attack was not possible. A year and a half later no improvement had occurred, and severe back pains persisted. In this case the sudden onset of paraplegia was probably due to vascular occlusion in the cord.

CASE 3—E. P., a Negro girl aged 13, had had acute meningitis of unknown type when 21 months old. Five years later she had begun to have severe disseminated root pains and progressive spastic paraplegia with atrophy. Examination revealed in addition irregular sensory disturbances below the first thoracic dermatome with a tendency to dissociation of pain and temperature senses. There were complete spinal block and scattered arrest of iodized oil at the third cervical and fourth and fifth thoracic vertebrae. At operation Dr. Eric Oldberg found a greatly thickened, opaque and vascularized arachnoid membrane, with two elongated arachnoid cysts. There had been no improvement two and one-half years later.

#### ARACHNOIDITIS ARISING SPONTANEOUSLY

CASE 4—Disseminated pains, paresthesias and progressive spastic paraplegia for three years; minimal superficial sensory loss, no spinal block, operation, death; advanced fibrosis and vascularization of arachnoid, with focal softening of cord.

**Clinical Abstract**—Mrs. G. B., a white woman aged 40, gave a history in March 1932 of disseminated pains, paresthesias and progressive weakness in the lower extremities for three years without significant antecedent phenomena. Examination revealed marked spastic paraplegia with only slightly diminished superficial sensibility but greatly reduced vibration and position sense in the lower extremities. The Babinski response was present on both sides. Painful spasms occurred in both legs. There was no block of the spinal fluid, the protein content was normal and the gold curve 2223221000. The spinal fluid Wassermann reaction was negative. At operation, Feb. 20, 1933, Dr. Eric Oldberg found the spinal arachnoid opaque, tough and vascular, and adherent to the cord. Nevertheless much of the membrane was dissected free. The patient's condition failed to improve and she died of an infection of the operative wound on the twenty-sixth day after operation.

**Autopsy**—The whole spinal arachnoid was thick and fibrotic and there were multiple foci of degeneration in the cord. Microscopically the arachnoid membrane consisted of almost solid collagenous connective tissue with no definite cystic areas and no infiltration except for occasional small mononuclear cells (fig 6). The fibrotic meninges were markedly vascularized and the vessel walls thickened often to complete occlusion of the lumen. The endothelial lining of the subarachnoid spaces

was hyperplastic wherever not overrun by fibrous tissue. Some of the spinal roots traversing the sclerotic meninges showed degeneration of both myelin and axis cylinders, with proliferation of the endoneurium.

In the spinal cord (fig 6) there was secondary degeneration of the fasciculus gracilis with marked reactive gliosis. In addition there was subpial degeneration leading at some levels to status spongiosus around the periphery of the section. Focal areas of degeneration were scattered elsewhere throughout the cord and varied in diameter from less than a millimeter to half the cross section of the cord. Some of these were old and gliotic, others were areas of recent softening, with equal degeneration of glia and white and gray parenchyma, without noticeable reaction. Ganglion cells in these regions had disappeared or degenerated without satellitosis or neuronophagia. Some were small and hyperchromatic, others swollen and pale with eccentric or broken-down nuclei. There was no cavitation or liquefaction. Blood vessels in the cord, like those in the meninges, were increased in number and their walls thickened, sometimes with occlusion of the lumen. There was no perivascular infiltration, but small recent hemorrhages were occasionally seen.

The clinical differences between this and the preceding cases lie in the absence of any history of antecedent acute meningitis and in the absence of signs of subarachnoid block. In other respects the syndrome was almost identical in all four cases. Pathologically, the resemblance to the appearances in case 1 is extremely close.

CASE 5—A D, a white man aged 39 fell and injured his right shoulder and knee in January 1932 with subsequent paresthesias for a few days in the lower extremities followed by progressive paraplegia, both sharp and aching leg pains, painful leg cramps, and eventually incontinence of urine and feces. Examination in May 1932 revealed advanced spastic paraplegia without atrophy or fibrillation. Abdominal reflexes were absent and the Babinski reaction was positive on both sides. All forms of sensation were normal. There was no subarachnoid block but the spinal fluid contained 56 mg of total protein per hundred cubic centimeters. Evidences of old

Fig 3 (case 1)—Cyst lined by epithelium in the fibrotic pia arachnoid. Van Gieson stain, reduced from a photomicrograph with a magnification of 60 diameters.

spondylitis were seen in roentgenograms of the spine. At operation, May 21, 1932, Dr Eric Oldberg found a thick, tough arachnoid membrane, adherent to the spinal cord. A few adhesions were broken down. Six months later weakness and atrophy were found in the left hand. Five years later he had greatly improved but still had a spastic gait, a positive Babinski reaction on both sides, and normal spinal fluid without a block. The achilles reflexes were now absent.

There is a suggestion that trauma may have played a part in this case. No history of meningitis was present. Again, as in case 4, no subarachnoid block was present. The diagnostic features consisted of the diffuse paresthesias and pains with cramps, the eventual presence of atrophy in the hands and the loss of the

Fig 4 (case 1)—Ventral horn with destruction of many ganglion cells and pyknosis of others; note proliferation of adventitia and hemorrhage about vessels. Toluidine blue, reduced from a photomicrograph with a magnification of 60 diameters.

previously exaggerated achilles reflexes. In this case alone, of the five reported, operation was followed by improvement.

#### COMMENT

**Etiology**—In three of the five cases reported the arachnoiditis appeared to result from some form of acute meningitis. The organism was probably the meningococcus, although such an opinion is hypothetical. In the last two cases the condition arose apparently de novo, a circumstance often recorded in the literature. In general the literature on the etiology of chronic adhesive spinal arachnoiditis indicates three possibilities. The first is infection, which may be meningococcal,<sup>21</sup> pyogenic,<sup>22</sup> syphilitic,<sup>23</sup> influenzal,<sup>24</sup> gonorrheal,<sup>25</sup> herpetic,<sup>26</sup> typhoid<sup>27</sup> or even tuberculous.<sup>13</sup> Cases have been reported of arachnoiditis following

so-called lymphocytic meningitis<sup>28</sup> and various forms of meningo-myo-encephalitis. In an article on the latter disease, Biernond<sup>29</sup> has contributed from Brouwer's clinic an interesting pathologic description of an acute form of meningo-myelitis with extensive inflammatory and necrotic changes in the cord. The second etiologic possibility is trauma, of which numerous examples have been recorded.<sup>30</sup> Mauss and Kruger<sup>9</sup> recorded twenty-three cases of arachnoiditis resulting from war injuries to the spine, and Elkington<sup>9</sup> reported nine instances, in six of which trauma was the sole cause. As pointed out by Paulhan, Fortunesco and Tudor,<sup>30</sup> fracture of the vertebrae is not necessary in the production of post-traumatic arachnoid adhesions. In many cases mere concussion of the spine suffices. The third type of arachnoiditis is that secondary to other pathologic changes in the cord or spine. Arachnoid adhesions are commonly seen in the neighborhood of tumors of the spinal cord or meninges. Spondylitis is said to be one cause of secondary arachnoiditis.<sup>31</sup> In recent years French investigators have emphasized arachnoid adhesions arising as a reaction to various diseases of the spinal cord, such as multiple sclerosis,<sup>31</sup> syringomyelia<sup>32</sup> and Friedreich's ataxia.<sup>33</sup> In view of the changes in the cord in cases of severe arachnoiditis, this theory must be doubted

Fig. 5 (case 2).—Operative appearance. The thickened arachnoid contained gelatinous substance and was very vascular. The spinal cord was almost invisible beneath tortuous vessels. Plaques of calcium on arachnoid.

and the possibility kept in mind that the arachnoiditis may be the primary factor and the cord changes secondary.

**Clinical Features**—Clinically, chronic spinal arachnoiditis closely resembles extramedullary tumor of the spinal cord, especially when the arachnoiditis is limited to the formation of a single arachnoid cyst. The two conditions have in common radicular pain, slowly progressive weakness and spasticity of the extremities, impaired sensibility, exaggeration of tendon reflexes, pathologic plantar responses, and impairment of sphincteric function. In addition, the spinal fluid formula is often the same for the two conditions, consisting essentially of From's syndrome with a block on Queckenstedt's maneuver. Because of these striking similarities, chronic arachnoiditis is often mistaken for tumor until operation. However, an analysis of the cases here presented reveals certain differential characteristics.

In the first place, if the chronic phase follows immediately after acute meningitis, there can be little chance of a mistaken diagnosis. If the onset of the chronic phase is delayed for years after the acute disease, or if no history can be obtained of an acute stage, differentiation can often be based on the evidences of diffuse involvement of the spinal cord and roots in arachnoiditis. The pains and paresthesias in spinal arachnoiditis are widespread rather than focal and change in character and location from time to time. This feature was noted in cases 1, 3, 4 and 5 and less definitely in case 2. Sometimes the pain is poorly localized by the patient, who speaks of it as deep, aching or diffuse. Again the superficial sensory disturbances found at examination are often vague, bizarre or inconsistent in distribution and may be absent. Only in case 2 was there a marked sensory loss with a sharp level such as one expects to find with spinal cord tumor. Deep sensibility, on the other hand, and especially vibration sense, was markedly reduced or absent in the lower extremities in all but one case.

The paraplegia due to chronic adhesive arachnoiditis is not always of the spastic type, having been flaccid in cases 1 and 2 of this group. Atrophy appeared late in all five cases and was not located in a single myotome but was scattered and irregular, indicating widespread involvement of the lower motor fibers. Fibrillary twitches were not seen, but large fascicular contractions were noted in a few instances. Not infrequently, painful gross muscle spasms were a troublesome symptom, occurring in cases 1, 4 and 5. Tendon reflexes were not uniformly exaggerated, as they usually are in cases of spinal cord tumor, but were often inconsistent, some being reduced and others increased in the same case. This reduction of some of the deep reflexes, like the scattered muscular atrophy, suggests the involvement of some of the lower motor fibers as they pass the meninges.

Spinal fluid block, a sign nearly always present in paraplegia due to extramedullary cord tumor, is some times not found in cases of chronic adhesive arachnoiditis. No such block was found in cases 4 and 5 of this group, viz those in which there had been no acute meningitic onset. When there is no block, the total protein content of the spinal fluid is not increased. Finally, when an injection of iodized oil is made, roentgenograms of the spine may reveal an arrest of the oil at multiple levels, as in two cases in this series.

**Pathology**—The two cases studied pathologically illustrate two etiologically different types of chronic adhesive spinal arachnoiditis. The pathologic charac-

teristics, however, were almost identical in the two cases, both in the meninges and in the spinal cord itself. The tissue reactions therefore seem more or less stereotyped, regardless of differences in cause.

The meningeal changes in both cases consisted of chronic inflammation, with some mononuclear infiltration but chiefly with marked fibrosis, thickening and extensive vascularization of the pia-arachnoid. The walls of the new vessels in the sclerotic arachnoid had undergone progressive thickening both of the adventitia and of the intima, many eventually becoming occluded. The meshes of the arachnoid were cystic and lined with arachnoid epithelium. Many roots of the spinal cord passing through these sclerotic meninges had degenerated.

The most important lesions, however, were those in the spinal cord itself, and these were unquestionably due to vascular occlusion. Such occlusive vascular changes in the spinal meninges as were seen in these cases must reduce the blood supply to the cord through the small penetrating vessels which supply the outer portions of the white matter. Thus arises the random degeneration reported previously and present in my two cases. This subpial degeneration was not a diffuse process in these cases but was made up of discrete and confluent focal areas of degeneration produced by the occlusion of varying numbers of the penetrating arteries. This tendency to vascular occlusion also affected the anterior spinal artery and its anterior fissural branches to the gray matter and central portions of the cord.

The exact neuropathologic characteristics of such areas of degeneration, whether in gray matter or white, seem to depend largely on the suddenness of vascular occlusion. All such regions are undergoing what is essentially anemic necrosis, but gradual chronic occlusion apparently leads to parenchymatous degeneration with secondary gliosis. In the white matter this process leads to a form of status spongiosus and rich proliferation of glia, in the gray matter slow anemic necrosis leads to a degeneration of the ganglion cells, with some gliosis, but not to neuronophagia. Sudden vascular occlusion leads to rapid softening, with death of glial as well as parenchymatous tissues and massive production of fat and little or no reaction—an anemic infarct, in short. These ischemic areas of degeneration in the cord, whether of sudden or gradual occurrence, constitute a disseminated type of focal destruction which may superficially resemble multiple sclerosis but which differs pathologically in its tendency to involve gray and white matter indiscriminately and, when acute, in the relative absence of gliosis.

Inflammatory changes were strikingly absent in the spinal cord in both case 1 and case 4. There was in no sense a myelitis, and the infection appeared to be restricted to the meninges. Neither were the changes attributable to mechanical injury to a cord fixed by adhesions in a mobile spine, as Stookey suggested.<sup>34</sup> Cavitation in the central regions of the cord in chronic arachnoiditis has been recorded by other workers.<sup>34</sup> It is a condition easily mistaken pathologically for syringomyelia (primary ependymal gliosis and cavitation). The theory that syringomyelia is primarily a degenerative disease may have been based erroneously on the observation of such cavitation.<sup>35</sup> In any event, cavi-

tion of the cord may occur as a result of chronic arachnoiditis, and future studies on "syringomyelia" must take this into account.

**Therapy**—In view of the pathologic conditions present, the treatment of chronic arachnoiditis is necessarily difficult. The only rational therapy would seem to be an attempt to break up the adhesions, evacuate cystic collections of fluid and remove the sub-arachnoid block if possible. But the arachnoid adhesions are often so widespread and vascular that surgical attack is almost impossible. Furthermore, the blood supply to the cord tangled in the thickened pia-arachnoid, is apt to be impaired by dissection. Operation was performed in all five of my cases. Two patients died, two were unimproved and only one was clinically benefited. With the last, the operation was performed early, before the changes were marked. The advantages of surgical intervention are thus limited. Nevertheless, many good results have been reported from operation<sup>36</sup> which would seem most valuable in early stages and when there are only localized arachnoid cysts. With more advanced lesions the surgeon should restrict his efforts to evacuating cysts and attempting to relieve sub-arachnoid block without disturbing the blood vessels.

Fig. 6 (case 4).—Fibrotic thickening and infiltration of arachnoid, partial demyelination of spinal roots and of subpial white matter, light secondary degeneration in dorsal columns and focal softening in dorsal horn and lateral column. Weigert-Pal and van Gieson stain, reduced from a photomicrograph with a magnification of 7 diameter.

Efforts to clear out widespread dense or vascular adhesions will result in serious operative hemorrhage or extensive infarction in the cord.

Medical treatment should include specific measures when the cause is syphilis. Roentgen therapy, recommended by Selinsky and Harris<sup>37</sup> has a doubtful rationale but may be tried.

#### SUMMARY AND CONCLUSIONS

In three of the five cases of chronic adhesive spinal arachnoiditis reported the condition was secondary to acute meningitis, and in the others it apparently arose spontaneously. Autopsy was carried out in two cases.

Clinically, such cases differ from those of extramedullary tumor of the spinal cord in the evidences of a diffuse disturbance of the spinal cord and roots, such as widely scattered paresthesias and pains, irregular and inconstant sensory disturbances, muscular atrophy and large fascicular twitches, painful muscular spasms, a mixture of exaggerated and diminished tendon reflexes and arrest of iodized oil at multiple levels. Spinal sub-arachnoid block may be absent.

Pathologically there are chronic adhesive or cystic fibrosis and vascularization of the spinal leptomeninges, with injury to the roots and secondary degeneration of

the dorsal columns. Thickening and occlusion of the blood vessels occur in both the meninges and the cord with marginal degeneration of the white matter nearest the pia, and focal areas of softening in the cord, which may lead to cavitation.

Surgical intervention is of value in early stages, with only localized arachnoid cysts, but may be harmful in advanced stages with diffuse adhesions.

#### ABSTRACT OF DISCUSSION

DR JOHN B DOYLE, Los Angeles. Dr Mackay has made a valuable contribution to the subject of chronic adhesive spinal arachnoiditis. There has been a dearth of reports of careful studies at necropsy, by which it will be possible to reach an understanding of the pathogenesis of this condition and the mechanisms of production of symptoms and to establish a sound basis for prognosis. This presentation serves to dispel certain assumptions that have crept into the literature and to provide a more inclusive clinical picture of this entity. Dr Mackay has shown that the clinical course may be a matter of a few weeks or of several years. When the damage to the vascular supply of the spinal cord involves not only the subpial vessels but the anterior spinal artery, one may encounter paraplegia, profound sensory changes and disturbance of the vesical and anal sphincters. In certain instances many of the symptoms and signs are attributable to direct damage to the posterior spinal nerve roots. When complete spinal subarachnoid block obtains, From's syndrome may be present. There may or may not be associated pleocytosis. Dr Mackay has emphasized the importance of trauma in a restricted group of cases. Keschner, Davison and Selmsky described an unusual case in which the picture developed after laminectomy for removal of a tumor of the spinal cord. In the majority of instances, however, the essential etiologic factor appears to be purulent or nonpurulent infection of the meninges. Frequently the initial meningeal process seems to have been subclinical or asymptomatic. Obviously the prognosis must be poor when there is evidence of extensive damage to the spinal cord or cauda equina. The severity and the extent of the process may be so great as to preclude successful surgical intervention.

DR J. M. NIELSEN, Los Angeles. Dr Mackay has made an important contribution. Frequently one observes an irregular picture of subacute combined degeneration or atypical amyotrophic lateral sclerosis and is not satisfied with the diagnosis. In 1924 I saw a patient who had been ill for a year with what was diagnosed as epidemic encephalitis. He came from the Philippine Islands. When I saw him he had symptoms referable to the spinal cord, with evidence of block, sphincteric disturbance and weakness of the lower extremities. I did a spinal puncture between the fifth lumbar and the first sacral vertebra and got 2 or 3 cc of spinal fluid. Then I went up one space and got 2 or 3 cc again and moved up one more space and got the same amount, I never could get any free flow, there was a complete block. I felt that nothing could be done. Then I saw a man who had spinal meningitis or leptomeningitis following skull fracture, and spinal punctures showed a thick, purulent fluid due to *Bacillus mucosus capsulatus*. With spinal drainage and application of mercuriochrome, which was in vogue at that time, he was cured. Six years later I was called into court to testify in the case. The patient had recovered and had been back at work all those years, but he had been jarred slightly in a street car in Los Angeles. He was suing the street car company because he found that his spine was stiff and his neck a little rigid, and he could not move his lower extremities easily.

DR R. P. MACKAY, Chicago. I will add only that chronic adhesive spinal arachnoiditis should be kept in mind in cases of so-called paraplegic multiple sclerosis. In such cases, without real evidences of disseminated lesions the diagnosis has always struck me as doubtful. I am convinced that multiple sclerosis is frequently diagnosed clinically on inadequate grounds, and in a certain proportion of these cases arachnoiditis may play a role.

## EXTRARECTAL METASTATIC GROWTHS FROM UPPER ABDOMINAL AND MAMMARY CANCER

REPORT OF SEVENTEEN CASES

HARRY E. BACON, M.D.

PHILADELPHIA

The relative frequency with which extrarectal metastatic deposits are encountered, the realization that the condition is seldom recognized and the fact that the condition has been confused with and incorrectly diagnosed as primary rectal carcinoma prompt a brief discussion of this entity, since it invades many fields of scientific medicine.

Seventeen cases that have come under my observation during a comparatively short period are reported here.

CASE 1—J. W., a Negro aged 49, admitted to the hospital April 3, 1937, because of abdominal pain, had been in good health until the previous January, when pain was experienced in the pit of his stomach immediately after eating. During the past two weeks difficulty, as well as frequency, and a burning sensation on urination had been noted. Bowel movements had been associated with straining for the past month, the stools had been tarry for several weeks. The patient said that he had lost 15 pounds (6.8 Kg.) in three weeks. The family history was irrelevant. On physical examination a mass the size of a walnut was palpated in the right upper quadrant at the edge of the rectus. By rectum a large irregular mass was felt anterior to the wall, which was thought to be a malignant growth on the prostate. The urine was yellow and alkaline, the specific gravity was 1.022, there was no albumin or sugar, and occasional epithelial cells were seen. A blood count showed 4,040,000 erythrocytes, 78 per cent (12 Gm.) of hemoglobin and 13,700 leukocytes, with 64 per cent polymorphonuclears, 25 per cent lymphocytes, 4 per cent monocytes, 6 per cent eosinophils and 1 per cent basophils. The Wassermann and Kahn tests of the blood were negative. Chemical analysis of the blood showed 82 mg of sugar, 11 mg of urea, 118 mg of cholesterol and 78 mg (66 per cent) of cholesterol esters per hundred cubic centimeters. The icterus index was 7. The total protein content was 6.62 mg per hundred cubic centimeters, the albumin making up 4.19 mg and the globulin 2.43 mg. The feces showed no parasites or ova. Gastric analysis showed no free hydrochloric acid, 12 units of total acid, a trace of occult blood and no starch. Cystoscopic examination April 6 disclosed no residual urine, moderate generalized cystitis, distortion of the vesical neck and no evidence of intravesical malignant growth. X-ray examination April 20 showed the stomach normal in outline, size and position, marked evidence of hyperperistalsis and hypermotility and no defects along the walls or curvatures. A normal duodenal cap was outlined. There was no six hour gastric retention, barium sulfate was present from the terminal portion of the ileum to the middle of the descending colon. An opaque enema showed no pathologic lesion of the rectum or large intestine. X-ray examination April 26 revealed no evidence of metastases to the lumbar vertebrae or the bones of the pelvis. No biliary calculi could be demonstrated on the flat film. The liver was seen but was not enlarged. In cholecystograms made April 29 the gallbladder showed no function. No calculi could be demonstrated. A flat plate of the right kidney and a retrograde pyelogram May 9 showed that both kidneys were apparently functioning, though at no time was much dye evident. The dye was seen better in the right kidney, and there was no evidence of hydronephrosis. The flat film showed no evidence of calculi. Neither kidney was mobile.

With the provisional diagnosis of primary malignant growth of the gallbladder or prostate and partial intestinal obstruction the patient was transferred to the radiologic department.

From the Radiologic Department of the Philadelphia General Hospital and the Proctologic Department of the Temple University Hospital. Read before the Section on Gastro-Enterology and Proctology at the Fifty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

Examination of the rectum showed it to be almost completely obstructed by a large extrinsic horseshoe-like mass on the anterior and both lateral aspects. The process was hard, nodular, asymmetric and distinctly outside the rectal wall. The mucous membrane was movable. Between the lower edge of the extrarectal mass and the smooth dome of the prostate a horizontal crevice could be noted by the examining finger.

May 28 an exploratory laparotomy was performed, which showed carcinoma of the head of the pancreas, with metastasis to the parietal peritoneum, omentum and mesosigmoid. The rectovesical pouch was literally filled by a large nodular growth. The patient died, but autopsy was not permitted.

CASE 2—F D, a white man aged 60, admitted to the hospital Aug 2, 1937, because of "bowel trouble," stated that he had been fairly constipated for the past year and during the past four months had been compelled to take increasing amounts of various laxatives. The stools were watery. The abdomen appeared normal, but rectal examination August 3 revealed a large, hard nodular mass located in Blumer's shelf. There was no palpable or visible evidence of an intrinsic process. The diagnosis was extramural malignant growth from some upper intestinal site. X-ray examination August 7 disclosed a large filling defect at the pars media of the stomach, extending to the pyloric end. The irregularity and defect were seen fluoroscopically and on all films. There was no six hour gastric retention. The diagnosis was malignant growth of the stomach. This patient was discharged after receiving high voltage roentgen therapy and died at his home one month later.

CASE 3—J L, a white man aged 48, admitted to the hospital Oct 9, 1936, because of pain in the right costal region and loss of weight, had been well until the previous April, when he noticed a sharp pain under the ribs on the right side. This had been more or less constant but worse at night. There was no relation between the pain and eating. He had been constipated for many years, there had been no tarry stools. He had lost 27 pounds (12.2 Kg) in six months. Physical examination of the abdomen gave negative results, by rectum a stony-hard fixed mass, approximately the size of a large orange anterior to and encroaching on the rectal wall was palpated. The lumen of the rectum was almost entirely occluded. An exploratory laparotomy November 4 showed generalized carcinomatosis, the omentum being infiltrated with small mucoid nodular growths. Biopsy showed carcinoma mucoid variety, secondary in the omentum. The patient was discharged but returned to the radiologic service, where high voltage roentgen therapy was given. Necropsy March 5, 1937, disclosed primary adenocarcinoma of the ascending colon type 3, mucoid variety, secondary carcinoma of the lymph nodes and a large metastatic deposit in the rectovesical pouch, causing partial obstruction.

CASE 4—N F, a white man aged 55 admitted Oct 28, 1937, because of intermittent constipation and diarrhea and pain in the lower part of the abdomen, stated that for four months he was compelled to take laxatives and enemas, after which the diarrhea became a more or less prominent feature. The abdomen was found to be tense, with dullness in the flank. By rectum a firm constriction, which would not permit passage of the finger, was felt approximately 2 inches above the ano-rectal line. The process was more marked on the anterior wall, the mucous membrane was nonulcerated and movable over the mass. The diagnosis of primary carcinoma of the rectum was made. Biopsy showed chronic inflammatory tissue, so that another diagnosis was made of primary carcinoma of the prostate. Cystoscopic examination showed no evidence of a malignant process. X-ray examination October 29 disclosed an abnormal contour of the rectum; an opaque enema showed no other evidence of a pathologic lesion. Exploratory laparotomy was performed December 20 at which time carcinoma of the ascending colon with widespread intra abdominal metastases was found. Biopsy showed adenocarcinoma secondary in the mesentery, an extensive collar-like nodular mass was found impinging on and completely encircling the rectum. The patient died December 22, autopsy was not permitted.

CASE 5—J O H, a white man aged 70, admitted to the hospital March 3, 1936, because of pain in the stomach, stated that the pain was dull and continuous but worse after meals and radiated to the right arm. There was no vomiting. He

had lost 10 pounds (4.5 Kg) in six weeks. In the past history "stomach trouble" for thirty years was cited. Physical examination gave negative results except to reveal a firm irregular mass the size of an egg, 4 cm above the anal margin. The patient was transferred to the radiologic department, with the provisional diagnosis of carcinoma of the rectum. Examination of the rectum March 5, 1938, showed a fixed nodular growth anterior to the rectal wall. The mucosa was freely movable and devoid of ulcerative change. There was extrarectal metastatic malignant growth. The patient was too weak to be studied. Necropsy March 15 showed adenocarcinoma type 3 of the head of the pancreas, with multiple intra-abdominal metastases, especially in the rectovesical pouch.

CASE 6—D McC, a white man aged 50, admitted to the hospital Feb 8, 1937, because of pain in the stomach, had been in apparent good health until three weeks before, when he became conscious of pain in the right lower quadrant, not severe but constant. He had lost about 10 pounds (4.5 Kg) in six months. Through the right anterior part of the abdominal wall a hard, fixed mass was palpable. By rectum a large nodular growth was felt anteriorly, approximately 3 inches above the anal margin. A diagnosis of primary malig-

Fig 1 (case 7) —Metastatic lesion showing a similar picture with more marked stromal reaction. The cells again occur in strands and singly for the most part rather than in any organoid arrangement.

nant tumor of the rectum was made. X-ray examination following a barium sulfate enema February 14 demonstrated a defect in the ascending colon just distal to the cecum. Reexamination March 8 confirmed the presence of a filling defect. An exploratory operation was done March 15 at which time an extensive carcinoma of the ascending colon was found. A nodular mass was palpated in the rectovesical pouch. Biopsy of the parietal peritoneum and omentum showed adenocarcinoma type 4 of the colon. The patient died March 30, but autopsy was not permitted.

CASE 7—A G, a white man aged 39, admitted to the hospital Sept 22, 1937, because of abdominal pain and difficulty in swallowing, had been apparently well until May 1937, when he noticed a dull gnawing pain in the right upper quadrant of the abdomen which occurred immediately after eating. X-ray examination by Dr Holmes October 20 showed marked contraction of the entire stomach. Fluoroscopically there was so much contraction of the pars media and the pyloric end of the stomach as to permit little barium sulfate to pass through into the duodenum.

As evidenced by rectal examination, two hard masses approximately the size of a small walnut were palpable anterior to and outside the rectal wall. The mucosa was freely movable over the metastatic deposits. The abdomen was explored October 27 during nitrous oxide anesthesia, and an extensive

carcinoma of the stomach with evidence of widespread metastasis and nodules in the rectovesical pouch was seen. Biopsy of the stomach showed adenocarcinoma grade 4, the growth in the culdesac showed metastatic carcinoma. The patient died March 13 1938. Autopsy showed scirrhous adenocarcinoma of the stomach. The right pelvic wall presented firm white lumps which surrounded the ureter and compressed it just proximal to the bladder. White pinpoint nodules were scattered along the pelvic wall in front and at the sides of the rectum.

CASE 8—M C, a Negress aged 58, admitted to the hospital in April 1938 because of abdominal pain, being extremely ill had difficulty in relating past events, but a relative stated that severe abdominal pain radiating to the back had been experienced for two months. No nausea or vomiting was present, the loss of weight was considerable, with progressive constipation. Examination showed the liver to be somewhat enlarged and the abdomen distended. Chemical analysis of the blood showed 112 mg of sugar, 70 mg of urea, 19 mg of phosphatase, 85 mg of calcium, 37 mg of phosphorus, 416 mg of cholesterol and 74 mg of cholesterol esters per hundred cubic centimeters. The icterus index was 218. The blood count showed

Fig 2 (case 10)—Retroperitoneal fibrosarcoma made up of interlacing bundles of young fibroblasts showing considerable pleomorphism anaplasia and a moderate number of mitotic figures. The tumor is highly vascular. Metastatic lesion showing similar structure but with evidence of greater malignancy. The cells are more irregular in size and shape, the nuclei are much more hyperchromatic. There is considerable necrosis.

5 440 000 erythrocytes, 91 per cent (14 Gm) of hemoglobin and a differential count of 72 per cent polymorphonuclears, 24 per cent lymphocytes and 4 per cent small lymphocytes. Autopsy May 8 disclosed primary carcinoma of the common bile duct, with generalized carcinomatosis. There were numerous metastatic nodules in the culdesac.

CASE 9—W C, a Negro aged 67, was admitted to the hospital April 28 1937, complaining of soreness about the umbilicus. This had begun three months before, after he had lifted a concrete block, since that time he had experienced frequent attacks of pain radiating through the abdomen. Weakness and loss of weight (60 pounds [27.2 Kg]) in six months were cited. The abdominal wall below the umbilicus was tender to the touch and small hard nodules were palpable beneath the skin. By rectum a slightly movable nodular mass, approximately the size of a tangerine, was found anterior to and encroaching on the rectal wall. The mucosa was freely movable over the growth and not ulcerated. The diagnosis was extrarectal metastatic malignant growth. Necropsy June 4 showed primary adenocarcinoma of the stomach type 3 and secondary carcinoma of the liver, gallbladder, spleen, pancreas, umbilicus and intra-abdominal lymph nodes. The rectovesical pouch was the site

of a few small implants and one large growth approximately the size of an orange.

CASE 10—E S, a Negress aged 53, admitted to the hospital June 21, 1937, with a mass in the abdomen, could not furnish a history because of an apparent toxic psychosis. Examination revealed a large mass involving the entire upper part of the abdomen. It was firm, nontender and immovable. Immediately above the pubis a hard subcutaneous nodule about the size of a walnut was palpated. By rectum a large hard nodular mass was felt anterior to the wall. X-ray examination June 1 disclosed that in the supine position the stomach was elongated and barium sulfate incompletely filled the stomach, owing to extrinsic pressure along the lesser curvature. The mucosal rugae in the pars media were clearly visualized, and the pylorus appeared to be flattened as a result of the enlarged liver. Autopsy July 5 disclosed retroperitoneal tumor and neurogenic sarcoma with involvement of the heart, lungs, liver, adrenals and retroperitoneal lymph nodes. Beneath the peritoneum and anterior to the rectum a large metastatic process was found.

CASE 11—W H, a white man aged 62, admitted to the hospital Jan 31, 1938, because of pain in the stomach, stated that he had been well until ten weeks before, when there developed pain in the epigastrium after meals and gaseous distention. Physical examination showed some rigidity in the upper midepigastrium. Gastric analysis showed no free hydrochloric acid, 30 units of total hydrochloric acid and some occult blood. Gastrointestinal study revealed that the stomach was small, contracted and somewhat fixed. Rectal examination showed three palpable nodular masses in the rectovesical pouch. All were immovable and hard. An exploratory laparotomy February 21 showed an extensive carcinoma of the stomach with generalized visceral and parietal peritoneal metastases. A nodule removed at operation was reported to show adenocarcinoma of the stomach, secondary in the peritoneum. At autopsy February 22 primary scirrhous carcinoma of the stomach was seen, with implantation carcinoma of the intestine and peritoneum. The abdominal lymph nodes showed metastatic carcinoma and numerous implantations of carcinoma in the region of the sigmoid flexure and in the rectovesical pouch.

CASE 12—H G, a white woman aged 37, admitted Jan 5 1934, to the Philadelphia General Hospital because of swelling in the breast, stated that in April 1933 she had noticed three small lumps in the left breast. She had been operated on at another hospital after three months, during which period the lumps had become egg sized, only the masses were removed. The following September nodules developed throughout the left breast and axilla. Roentgen therapy was then administered. She now complained of pain in the left shoulder and lumbar region, as well as shortness of breath. Physical examination showed an oblique scar representing left radical mastectomy, numerous small glands in the left supraclavicular region and a tumor mass occupying the entire right breast, with large glands in the right axilla. X-ray examination January 16 by Dr H W Ostrum showed metastatic carcinoma of the lungs. Autopsy March 3 showed adenocarcinoma type 4 secondary carcinoma in the lungs and shaggy masses in Douglas pouch. Nodules varying in size from that of a pea to that of a pinhead were scattered all over the peritoneum. In Douglas pouch they were confluent.

CASE 13—A B, a white man aged 43, admitted to the hospital Dec 15, 1936, because of pain in the stomach, described the pain as dull, worse after meals and associated with some vomiting. He had passed tarry stools mixed with some bright red blood for eight months. The report from another hospital showed that he had been operated on one year previously for gastric ulcer. There was a questionable mass in the upper right quadrant of the abdomen and a circumferential extrinsic narrowing of the rectum. The mucosa was nonulcerated and movable over the mass. Gastrointestinal study by Dr H W Ostrum December 18 with the patient erect showed a large filling defect of the lesser curvature involving a greater portion of the pars media and pars pylorica. There were moderate deformity of the pyloric end of the stomach and flattening of the duodenum especially of the first portion. In two hours there was approximately 30 per cent retention. The diagnosis

was carcinoma of the lesser curvature involving the pars media and pars pylorica. Punch biopsy of material taken from the extrarectal growth through the rectum showed metastatic adenocarcinoma. Extensive high voltage roentgen therapy was given. To my knowledge the patient is still living, in another state.

CASE 14—M St P, a white woman aged 47, admitted to the hospital April 19, 1937, complaining of pain in the abdomen, stated that she had felt a mass in the abdomen the previous December and that she vomited after eating any type of solid food. The remainder of the history was irrelevant. Physical examination showed an emaciated woman with a hard nodule in the left supraclavicular fossa and a definite hard nodular mass in the left side of the hypochondrium, extending along and under the costal margin. The latter nodule, approximately the size of a lemon, was movable. By rectum a large hard nodular growth anterior to and outside the wall of the rectum was palpated. The mucosa was freely movable. X-ray examination April 14 disclosed marked narrowing and fixation of the cardiac end of the stomach and pars media. There was irregularity along the lesser curvature. Autopsy showed primary adenocarcinoma of the stomach with widespread metastasis. A large metastatic deposit was seen in the recto uterine pouch.

CASE 15—J C, a white man aged 47, admitted to the hospital Dec 3, 1937, because of pain in the epigastrium, stated that he had been well until two months before, when he noticed pain in the shoulder and in the ribs. The patient was given medication, but he said that it seemed to aggravate the discomfort. Finally he was unable to eat because of the pain, there was no nausea or vomiting. He had been markedly constipated during this period and had lost considerable weight. The lower edge of the liver was palpable. A mass the size of a fist was felt in the upper quadrant, slightly to the right of the midline. There was considerable ascitic fluid. By rectum a large smooth fist-sized mass was palpable anterior to the rectum and encroaching on it. The mucous membrane was freely movable. Autopsy showed primary type 4 adenocarcinoma of the stomach with generalized carcinomatosis. The rectovesical pouch was readily filled with numerous small and one large metastatic growth.

CASE 16—C F, a white woman aged 63, admitted to the hospital Jan 24, 1937, because of pain in the head, had noticed a lump in the left breast for which she was treated with ultraviolet rays early in 1936. In the spring of the same year she noticed stiffness of the neck and pain in the head, arms and legs. She had lost considerable weight. An increase in constipation was experienced. Examination showed the left breast to be hard and fixed, with definite retraction of the nipple. There was no axillary or supraclavicular adenopathy. X-ray examination January 24 disclosed extensive carcinomatous metastasis to the skull, jawbones and cervical and dorsal vertebrae. Some of the ribs were involved. There was possible involvement of the acromion process. Extensive high voltage roentgen therapy was given. She returned to the radiologic clinic April 21, 1938. At this time she complained of pain in the abdomen, pain at defecation and increasing constipation. Multiple hard nodules were felt through the anterior part of the abdominal wall. By rectum a hard irregular collar-like mass partially encircling the anterior portion was palpable. The mucous membrane was movable over the extrinsic constriction. The patient is still living.

CASE 17—C O, a white man aged 55 was admitted to the hospital in January 1938 because of intermittent pain in the right lower quadrant of eight months' duration, dyspnea and loss of 15 pounds (68 Kg). Examination disclosed a hard fixed mass in the right upper abdominal quadrant ascites and, by rectum a hard nodular constricting process extrinsic to the wall. Autopsy May 22 revealed primary adenocarcinoma of the right kidney with generalized carcinomatosis and a rectovesical pouch obliterated by metastatic deposits encroaching on and constricting the rectum.

In the presentation of such a subject as this certain phases warrant some discussion. What is the historical background of this peculiar phenomenon? What is

understood by the "rectal shelf"? What is its significance? Where is the usual site of the primary growth? What is the mode of spread? From what is it to be distinguished? What is its prognostic value, and, finally, what form of treatment can be prescribed?

The earliest reference I have found is that by Strauss,<sup>1</sup> who some forty odd years ago reported a case of gastric carcinoma with metastasis to the pouch of Douglas. Four years later this investigator<sup>2</sup> cited two additional cases and mentioned that such metastasis not only may be early but may be the only manifestation. Schnitzler<sup>3</sup> in 1908 reported eleven cases, in one of which the pancreas and in all others the stomach was the primary site. Worthy of mention is this quotation from the original German: "The important feature was that all these patients consulted the doctor for symptoms produced by the metastasis, without having the slightest suspicion of the presence of the

Fig 3—Sagittal section showing the tip of the finger between the prostate and a growth on the culdesac: a supraserosal mass and b subserosal mass.

primary growth'. In his report Schnitzler mentioned that in one case he mistook the tumor for a primary rectal growth and performed a radical sacral extirpation. Further examination of the patient, who survived six months, revealed a gastric carcinoma of long latency. Payr<sup>4</sup> described a case in which he performed a colostomy for rectal stenosis due to periproctitic and parametric induration. The patient died of peritonitis, autopsy revealed a gastric carcinoma and the presence of perirectal metastasis of the infiltrative type. Additional cases were reported by Toyosumi,<sup>5</sup> Chiari,<sup>6</sup>

Orth,<sup>7</sup> Kappeler,<sup>8</sup> Kelling,<sup>9</sup> Kaufmann,<sup>10</sup> Brosch<sup>11</sup> and Bensaude and Okenczyk<sup>12</sup> Blumer<sup>13</sup> in 1909 reviewed the literature at hand in addition to reporting two cases, in one the primary site was the gallbladder and in the other the stomach. By virtue of his excellent description this extrarectal site has been referred to frequently as Blumer's shelf. Since that time few reports have been published,<sup>14</sup> although several quotations or reviews are to be found.<sup>15</sup>

Metastatic deposits in the culdesac under ordinary circumstances can be palpated through the anterior or anterolateral wall of the rectum according to their anatomic distribution. Growths the size of a pea may be felt occasionally, although it has been my experience that the size estimated by digital examination of the rectum is not always verified by operation or necropsy. Coalescence of these deposits, which vary in shape, size and number, produces a ledge spoken of as the rectal shelf.<sup>1</sup> In such a case digital examination of the rectum elicits a nodule or growth anterior or anterolateral to the rectal wall approximately 2 to 4 inches above the anal margin in the female or one-half inch above the prostate in the male. As would be expected, it is hard and not tender. Ordinarily a sulcus can be felt between the upper rounded border of the prostate and the mass. The mucosa of the rectum, being uninvolved, is freely movable over the growth, this, it should be remembered, is the main feature distinguishing it from primary carcinoma of the rectum. Increase in size and extent may readily cause impingement on the anterior rectal wall, in which case the examining finger encounters backward displacement of the rectum by a mass anterior to and outside its wall. Occasionally the metastatic process encircles the rectum so as to cause occlusion, either partial, as in cases 1, 4, 13, 15, 16 and 17, or complete, as in that reported by Chiari.<sup>6</sup> In each case the mucosa was freely movable over the growth. Of course it is possible, as reported by Kappeler,<sup>8</sup> for the process to infiltrate the rectal wall proper and cause fixation of the mucous membrane, under which circumstance it would not be unlikely that the resultant proliferating changes might be confused with primary carcinoma, yet in my series of cases, even those of almost complete obstruction, the mucosa was movable and free from ulceration. This condition is significant

in that patients may consult the physician because of symptoms produced by the metastasis without the slightest suspicion of an existing primary growth elsewhere. Such growths in themselves may direct attention to the primary malignant process in another site. That such metastatic deposits may cause narrowing of the rectal lumen, even to the point of complete obstruction, and that these tumors may be mistaken for primary rectal carcinoma are factors only too significant.

Judging from the available literature at hand as well as my own series of cases, the stomach is by far the most common primary site. Feldner<sup>16</sup> said that metastasis to Douglas' pouch occurs in 20 per cent of cases of gastric carcinoma and in 18 per cent of cases of carcinoma of the gallbladder. Such frequency I have been unable to confirm. The only cited case of involvement of the gallbladder is that of Blumer.<sup>13</sup> Schnitzler,<sup>3</sup> it will be recalled, reported involvement of the pancreas in one case and of the stomach in ten cases. Melchior<sup>17</sup> reported three cases, the stomach, esophagus and the breast were the sites. Both Handley<sup>18</sup> and Carnett<sup>19</sup> described three cases of carcinoma of the breast with metastasis to the culdesac. The sites in the reported cases are shown in table 2.

In referring to cancer of the breast the words of Handley<sup>18</sup> may be recalled. "It must never be forgotten that the first sign of epigastric invasion may be found not in the epigastric region, but in the pelvis." Eusterman and Balfour<sup>20</sup> have said "Although the gastrocolic and greater omentum are favorite sites, the most common situation is the pelvic peritoneum."

The question arises as to the manner in which the culdesac is invaded. While there is no conclusive proof as to the mode of spread, it seems pertinent to review briefly the opinions and investigations of various workers. By metastasis is understood the dissemination of a malignant growth either by continuous extension or by tumor cell emboli. Many writers lean toward dissemination by the hematogenic route, which, it is agreed, is the usual means of spread in the case of sarcoma (case 10). As I have previously stated,<sup>1</sup> it is recognized that an implantation type of cancer does exist, and several authentic cases have been reported. Carcinomatous implants in the abdomen, especially in cases of advanced disease, are not uncommon. The explanation first mentioned by Schnitzler is today almost universally accepted, in that pelvic involvement occurs by gravitation of fragments of cancerous tissue to the pouch, for it will be recalled that he attributed the relative frequency of the disease in males and rarity in females to malignant cells' reaching the rectovesical space in the former whereas they were caught by or

became engrafted on the ovaries in the latter Eusterman and Balfour<sup>20</sup> have said that apparently when the tumor reaches the gastric serosal layer, carcinoma cells are mechanically carried to the pelvis and there occasionally take root. This, however, while possible and highly probable, does not explain entirely the occurrence of an isolated metastatic pelvic deposit in the absence of other visible and palpable implants. In two instances sections of the smaller retroperitoneal lymphatic vessels in the lower dorsal and lumbar regions presented evidence of malignant invasion. Some investigators contend that lymphatic embolism and continuous permeation are commonly associated. Ewing<sup>23</sup> called it probable that the rapidly growing epidermoid and glandular carcinomas disseminate chiefly by lymphatic embolism, while the slowly growing and recurrent tumors often extend by continuous permeation. Retrograde flow through lymphatic and blood channels is a subject that always invites discussion. Organs in which there is a normal venous pulse or in which violent expiration or increase of intrathoracic pressure occurs

view that lymphatic permeation is a common process in the liver and that in other parts, especially the deeper or pelvic parts of the abdomen, lymphatic permeation may begin around implanted nodules. He differed, however, in expressing the belief that widespread lymphatic permeation may occur in the abdomen in the absence of implants.

A number of conditions may simulate a metastatic growth in the culdesac, and from these it must be differentiated. Among them should be mentioned adherent coils of small intestine and omentum encountered in certain types of peritonitis, especially the diffuse tuberculous variety, scybala in the small bowel, subperitoneal myoma, carcinoma of the sigmoid flexure prolapsing into the pouch, and chronic inspissated, partially encapsulated pelvic abscess in the process of organization, carcinoma of the upper pole of the prostate or of the posterior bladder wall infiltrating the rectum, loculated pelvirectal abscess, hypertrophied valve of Houston, endometriosis of the rectovaginal septum or distal part of the sigmoid flexure and extension from an ovarian or uterine malignant growth. No difficulty should arise in distinguishing primary rectal carcinoma except in rare instances in which the metastatic process infiltrates the rectal wall.

So far as prognosis and treatment are concerned, this sequence is of utmost importance in that it represents an advanced stage of the disease for which radical surgical measures are contraindicated. A palliative procedure, however, such as some type of enterostomy, may be performed according to the individual case.

#### SUMMARY AND CONCLUSIONS

Of seventeen patients with extrarectal metastatic malignant growth from remote sites, twelve were men and five women, thirteen were white persons and four Negroes. The ages ranged between 37 and 70, averaging 53 years. The stomach was the most frequent site of primary growth. As to type, sixteen tumors were adenocarcinomas and one was a sarcoma. Grading of the tumor was made in eight cases, four were of grade 4 and four of grade 3. In four cases the symptoms were suggestive of disturbance of the lower bowel.

In six instances the extrarectal metastatic process was diagnosed as a primary growth of either the rectum or the prostate. In five cases there was definite constriction of the rectum. In all seventeen cases the mucosa was devoid of fixation and ulceration.

Whereas in all cases in this series the disease was advanced, it must be realized that such metastasis may occur early and be the only extension. The condition is of importance in that it is not extremely rare, the symptoms may not direct attention to the primary site and the extrarectal process may be incorrectly diagnosed.

As a routine procedure careful palpation and visualization of the rectum in every case of suspected malignant growth are advocated.

1527 West Girard Avenue

#### ABSTRACT OF DISCUSSION

DR. NEWTON D. SMITH, Rochester, Minn. On reviewing Dr. Bacon's paper one notes that many efforts have been made to explain the occurrence of the so called rectal shelf in cases in which the primary lesion is in some distant part of the body. Yet none have been universally accepted or demonstrated. An unsolved problem has been offered. The mechanical, physiologic and pathologic aspects of this problem are worthy of further study. The element of diagnostic error in this series of cases

would be the most common sites. Occlusion of the main lymphatic or venous channels gives rise to disordered function, as a result of which retrograde flow, even though a slow process may supervene. Examples of retrograde venous and lymphatic flow have been cited by Heller, Bonome, Arnold, Ernst and von Recklinghausen, Vogel, Poncet, Most and Troisier.

Walther<sup>24</sup> believes that a large number of cases of alleged retrograde lymph node metastasis are instances of continuous dissemination, because in the majority of his cases he was able to demonstrate that diseased lymph nodes not in the vicinity of the primary growth represented regional metastases of an organ that had become involved by the hematogenic route.

Regarding carcinoma of the breast, Handley maintained that in nearly every case dissemination to the abdominal cavity occurs by transcelomic spread, the secondary deposits arising from gravitations of cancerous particles into the pelvis and that in the late stage the whole pelvis may be filled with cancer and its contents matted together. Carnett<sup>25</sup> concurred in the

is a severe criticism. In more than 34 per cent there was an error in the early diagnosis. This error consisted of discovering the primary lesion and overlooking the rectal shelf or, conversely, discovering the rectal shelf and, assuming it to be a primary lesion, failing to search further for the real source. The importance of an extrarectal metastatic growth as a factor in determining prognosis and treatment seems undeniable in view of the cases reported by Dr Bacon. If this were not so evident, my second point would assume only academic importance. The seventeen cases reported reveal that the life expectancy of the patient in whom a rectal shelf is discovered on examination is usually not more than several months. Assuredly, with this evidence radical or curative surgical procedures are contraindicated and only that surgery should be attempted which is necessitated by the physician's effort to prolong life or relieve actual suffering.

DR WILLIAM H DANIEL, Los Angeles. These extrarectal metastases or implantations present definite problems as to diagnosis because in the majority of cases the rectal lesion is the first noticed and the symptoms from the primary lesion are so mild that they are overlooked by the patient. When the rectum is constricted by an annular or localized mass and the mucosa is not involved and cancer of the cervix or prostate is ruled out, carcinoma in the upper part of the abdomen must be considered. Of twelve cases of this type that I have seen, eight were diagnosed as of remote origin six of which were confirmed at operation and one was confirmed by x-ray examination of the stomach, two were discovered at operation, one was discovered at autopsy and one patient with only a tentative diagnosis died without confirmation. The primary lesion in ten cases was located in the stomach in two, the pancreas in two, the adrenal gland in one, the sigmoid in three and the ovary in two. One of the early cases (a man in his fifties) had been in the hands of several very good men. The patient's only symptom was mild intestinal and urinary disturbance. Primary carcinoma had been diagnosed by a cancer specialist and radium therapy was advised. Examination of tissue from the rectal wall and prostate was negative for carcinoma. At autopsy a small scirrhous carcinoma was found in the stomach. In a man of 21 the rectum was practically occluded by a large mass protruding into the anterior rectal wall. At operation implants were found from the bladder to the diaphragm. Tissue examination revealed teratoma of the adrenal. As a rule, biopsy from the rectal tissue does not show carcinoma, because only the superficial tissue is obtained. In ten of the twelve cases the infiltration of the rectal wall was annular and in two cases localized. In one of the cases of primary ovarian carcinoma a polyp at 4 inches in the rectum showed adenocarcinoma. Although these lesions are not of frequent occurrence, probably more would be found if a rectal examination were made in all cases of carcinoma of the abdomen. In my own experience only twelve secondary or extrarectal growths have been found as compared to 437 primary carcinomas. Treatment in these cases is at best only palliative.

DR HENRY L BOCKUS, Philadelphia. I am sorry that the audience has not been greater to hear Dr Bacon's paper, because I feel that there are a good many of us who are not familiar with Blumer's shelf. I say that advisedly, coming in contact with students from all over the country, very few of whom have heard of Blumer's shelf when they arrive. It is a rather important thing to know that in carcinoma of the upper part of the abdomen there are a few locations that one should go over rather carefully for the possibility of metastases. It is my routine to feel above the left clavicle, in the left axilla, not forgetting to go deep under the pectoralis muscle, where the so-called Irish node is located, carefully palpate the umbilicus for any suggestion of a malignant growth, feel along the margin of the right rib to eliminate a malignant condition of the liver and feel the rectum on the anterior wall for a nodule or hard fibrotic shelf with a soft velvety mucosa over it. That is a Blumer shelf and in 95 per cent of the cases that means malignant infiltration. Dr Bacon didn't mention another cause for such a shelf. I have reference to abdominal tuberculosis with secondary inflammatory changes and fibrosis. The incidence of Blumer's shelf in a malignant condition in the upper part of the abdomen is comparatively rare. I believe there are not more

than two or three in a graduate hospital each year, but in a service at the Philadelphia Hospital, which I believe Dr Bacon has, I believe many more would be found, because in the last stage of this condition Blumer's shelf is not too infrequent. I should like to mention another fact and that is that Blumer's shelf may constitute the first lead to a correct diagnosis. Any patient in whom a malignant growth is suspected should have a careful rectal examination to eliminate Blumer's shelf. Most of my patients in whom a shelf was palpated through the rectal wall have come with a diagnosis of cancer of the rectum.

DR A H AARON, Buffalo. When one realizes that about 60 per cent of all the malignant lesions of the large intestine are within the reach of the examining finger and there is no field of malignancy that offers such great prognostic value as to cure it is evident that this should be a routine measure in physical examinations. As to the various metastatic nodes, such as the Ewald node in the left supraclavicular region, Irish's node in the axilla and Straus's shelf (Blumer) in the pelvic floor, a better term can be applied, they are sentinel nodes, outposts demonstrating the presence of a malignant condition elsewhere in the body.

DR HARRY E BACON, Philadelphia. I am appreciative of this discussion. Dr Bockus is quite right in saying that Blumer's shelf is found invariably in the late cases. Age, however, does not seem to play a great part.

## A NEW AND FUNCTION-RESTORING OPERATION FOR BILATERAL ABDUCTOR CORD PARALYSIS

PRELIMINARY REPORT

BRIEN T KING, M.D.

SEATTLE

In presenting a new operation for the relief of bilateral cord paralysis, it seems fitting first to discuss the general principles involved in operations previously done for that purpose. All previous attempts to relieve the condition can be classified under four general headings.

This discussion is limited to a consideration of those bilateral recurrent nerve paralyses which follow operations for goiter. I have made no study of postdiaphragmatic paralyses or those that occur as a part of the picture of progressive bulbar paralysis.

1 Permanent tracheotomy with insertion of a tube or with suture of the skin to the incised edges of the trachea so as to leave a permanent opening.

2 Nerve suture. The following nerves have been anastomosed to the distal portion of the injured recurrent nerve: (a) the proximal portion of the recurrent nerve, (b) the descendens noni, (c) the roots of the spinal accessory nerve and (d) the phrenic nerve.

3 Cordotomy or cordectomy either by punch operation or by laryngotomy with excision of one cord. This group of operations includes ventriculocordectomies, of which there are many modifications.

4 Cord displacements. These include all operations which are designed to displace one cord in a fixed outward position. Attempts have been made to split the thyroid cartilage and separate the anterior ends of the vocal cords by interposition of a piece of bone or cartilage. Others seat the anterior end of one cord in an outward position on the thyroid cartilage. Another creates a fixed outward displacement of one arytenoid cartilage.

No one of these operations has been productive of satisfactory results. The object of any operation should be to restore the functions of phonation and respiration.

Many of those devised were doomed to defeat in one or both of these objectives because of the very nature of the method chosen for attacking the problem. A brief discussion of the foregoing groups of operations will aid in a better understanding of the one subsequently described.

Tracheotomy has functioned more uniformly and satisfactorily than any other method. No one wants to wear a piece of plumbing in his windpipe, and at best a tracheotomy tube is a nuisance, though many patients are grateful for the relief so obtained. The desire to get away from the tracheotomy tube has been the father of all operations devised for the relief of bilateral abductor cord paralysis. That holds for the one herein described.

Nerve anastomosis would be ideal were it possible of success, as it would restore the functions of both phonation and respiration. Charles H. Frazier,<sup>1</sup> Sir Charles Ballance,<sup>2</sup> Frank H. Lahey<sup>3</sup> and others have written on the subject, but so far the results reported do not justify the adoption of that method of treatment as a standard procedure. For reasons later to be discussed, nerve suture will probably fail to secure good functional results even though nerve pathways are reestablished.

Cordotomies, cordectomies and cord displacements all have the same objections. It is not possible to alter permanently the position or physical structure of a vocal cord without creating a permanent change in the tone and quality of the voice. One might as reasonably remove the strings from a violin and replace them with hemp rope and expect it to produce the same tone and quality of sound as to cut out a vocal cord and expect the patient so deprived to speak in a normal manner. Sufficient air may be gained, though it is of necessity gained at the expense of the voice.

The operation I have developed is a new approach to the subject. The idea was borrowed from the procedures and practices of orthopedic surgeons. In principle it is based on the methods they use in dealing with motor nerve paralyses, whether they are of traumatic, toxic or infectious origin. I saw such surgeons transpose the tendons of functioning muscles to replace those of paralyzed muscles in the feet of children who were the victims of infantile paralysis. Some of those children were greatly benefited. The idea occurred to me that the same principle might be applied to the paralyzed vocal cords. This new approach is simple in its mechanics, physiologic in principle, and, furthermore, has worked with the patients operated on.

In order to understand it comprehensively, one must have a general knowledge of the mechanics of the larynx, its anatomy and all its functions as to both respiration and phonation, plus a knowledge of its action during deglutition.

The suprahyoid and infrahyoid groups of muscles are intimately concerned in all the functions of the larynx. Therefore a knowledge of them, their actions and their nerve and blood supply is also important. (Negus's<sup>4</sup> monograph more comprehensively covers

laryngeal function than anything else in medical literature.) Briefly, the suprahyoid muscles pull the larynx upward during the act of swallowing. These muscles are the digastric, geniohyoid, geniohyoglossus, mylohyoid, stylohyoid and middle constrictor of the pharynx. Opposing that group is the infrahyoid group, comprising the sternohyoid, sternothyroid, thyrohyoid and omohyoid. Their function is to counter the action of the suprahyoid group and to pull the larynx downward, partly as an aid in swallowing after the food bolus has entered the esophagus. Also they hold the larynx down and slightly depress it during inspiration. The mechanism of the larynx, which prevents foreign substances from entering it during swallowing, operates simultaneously with the suprahyoid group.

It is interesting that the suprahyoid and infrahyoid groups of muscles are both voluntary and involuntary in their actions. One swallows and breathes voluntarily, one also swallows and breathes involuntarily.

Fig. 1—Nerve supply to the omohyoid muscle. (Figures 1 and 2 are reproduced from Callandar C. L. *Surgical Anatomy* Philadelphia, W. B. Saunders Company, 1933.) 1 ramus marginalis mandibulae nervi facialis 2 vena facialis posterior 3 ramus submentalialis 4 vena facialis anterior 5 nervus hypoglossus 6 vena auricularis posterior 7, vena facialis communis 8, vena jugularis interna 9 musculus omohyoideus 10 ramus descendens nervi hypoglossi 11 nervus cutaneus colli 12 nervus ansa hypoglossi 13 vena jugularis anterior 14 musculus sternocleidomastoideus 15, vena jugularis externa 16 nervi supraclaviculares anteriores 17 nervi supraclaviculares medii 18 nervi supraclaviculares posteriores 19 plexus brachialis 20 trunks of supraclavicular nerves 21, ramus externus nervi accessorii 22 nervus occipitalis minor 23 nervus auricularis magnus 24 nervus cervicalis III 25 arcus venosus jugularis

The function of the omohyoid muscle is opposition to the suprahyoid group. This muscle also assists in depressing the hyoid bone and larynx on inspiration. It therefore contracts automatically on inspiration as a part of its involuntary function. Gray<sup>5</sup> stated that "the omohyoidei not only depress the hyoid bone, but carry it backward and to one or the other side. They are concerned especially in prolonged inspiratory efforts."

The success of the operation herein described is primarily due to the previously developed habit of this muscle to contract automatically during inspiration.

there is danger of injury to the internal division of the superior laryngeal nerve. At the inferior cornu there is danger of injury to the external division of the same nerve. Along the border of the thyroid cartilage are to be found the attachments of the inferior constrictor of the pharynx. These fibers must be cut. The esophagus is then exposed. The wall of the esophagus in the region immediately behind the larynx does not appear to contain either circular or longitudinal fibers, and care must therefore be exercised in separating it from the posterior surface of the cricoid cartilage.

The arytenoid cartilages articulate with the cricoid on its posterior and outer borders. They, with the cartilages of Wrisberg and Santorini, act like corset stays in a rather thin wall that separates the openings of the larynx and esophagus. The arytenoid cartilages sit on a facet-like joint and extend upward for about one-half inch. The esophagus must be separated from the posterior spinous border of the arytenoid cartilage. In this dissection, one must be careful to avoid making an opening into either the esophagus or the larynx. The muscular process of the arytenoid cartilage will be exposed in this maneuver. Immediately beneath the muscular process is the facet-like joint. This, like any joint that has been immobilized for years, is stiff and its ligamentous capsule contracted. I have found it advisable to mobilize the arytenoid cartilage by cutting the ligamentous capsule of its joint on three sides, the mesial, the outer and the posterior, the last of which also divides the atrophic fibers of the crico-arytenoideus posticus muscle.

The posterior border of the arytenoid cartilage is then scraped clean and the cuffed end of the omohyoid attached to it by silk sutures which pass through both the muscle and the arytenoid cartilage. In the aged, the cartilages of the larynx become ossified, rendering it difficult to pass a needle through the arytenoid without fracturing the cartilage. This occurred in the second case here reported. It is interesting to note that this patient secured the best result of any on whom the operation has been performed.

The cut fibers of the inferior constrictor of the pharynx are then sutured. This leaves the omohyoid passing through an aperture in the inferior constrictor. The platysma is closed with two or three interrupted catgut sutures and the skin with clips.

#### COMMENT

When the idea of this operation was first conceived, I thought that it should be applied to only one cord. This conclusion was based on the fact that patients with one cord paralyzed generally do not suffer much disability in either phonation or respiration. The paralyzed cord usually comes to rest in or near the midline position, which is the position of phonation. The opposite cord is thus able to approximate it on phonation and also open the larynx on respiration. If sufficient airway has been obtained by operating on one cord, there is no occasion to repeat the operation on the opposite cord. If for any reason the desired result is not secured in a given case there can be no objection to operating on the opposite side.

Examinations of the second patient on whom this operation was performed revealed some very interesting results. The operation was done on the left side. Two weeks later the left cord was observed to open automatically on inspiration. Furthermore, there was some capacity to adduct the cord at that time. At the end

of seven weeks there was sufficient abduction of the cord to permit the removal of the tracheotomy tube. The patient can adduct the cord as well as the normal person. It is more than three months since the omohyoid was transposed to the arytenoid cartilage. The tracheotomy wound has been closed for a month. The patient can talk and breathe practically as well as the normal person, has gained 16 pounds (7 Kg) and states that she can now comfortably eat and breathe at the same time. Her cords are easily visualized with a laryngeal mirror.

It is easy to understand her capacity to open the cord, but the ability to adduct it is a point about which there may arise a difference of opinion. I am of the

Fig. 4.—A posterior view of cricoid and arytenoid cartilages. 1 cornu late cartilage, 2 cuneiform cartilage, 3 arytenoid cartilage, 4 muscular process of arytenoid cartilage, 5 median ridge posterior surface of cricoid cartilage, 6 lateral view of cricoid cartilage. B lateral view of cricoid cartilage (note wide posterior portion making a completed ring). 1 facet for articulation with arytenoid cartilage, 2 facet for articulation with lower horn of thyroid cartilage, 3 anterior part of cricoid ring, 4 thyroid cartilage from behind showing interior surface, 5 epiglottis, 6 pits for glands in epiglottis, 7 superior cornu of thyroid cartilage, 8 ligament of epiglottis, 9 superior rim, 10 inferior surface of thyroid cartilage, 11 site for anterior attachment of true and false vocal cords. C posterior margin of cartilage, 9 inferior margin, 10 inferior cornu. D, lateral view of thyroid cartilage. 1 epiglottis, 2 superior cornu, 3 superior margin, 4 notch of thyroid cartilage, 5 inferior horn.

opinion that neither the interarytenoideus muscles nor the intrinsic muscles of the cord are necessary to produce adduction and tension of the cord under the conditions prevailing in this case. Evidently the faculties of adduction and tension of the cord are produced in this instance by the cricothyroid muscles, which are supplied by the superior laryngeal nerves, plus the contracted interarytenoideus fascia. However, the cricothyroid muscles are not capable of producing adduction or tension of a cord that has recently been paralyzed. This difference in action is presumably due to the fact that with recent nerve injury the cord is flaccid while with an old injury it is taut and contracted, so that when the cricoid cartilage is tilted backward,

further tension on the cord shifts it into the midline (fig 3) Stridor, which was pronounced in this case prior to operation, is entirely absent, even on deep inspiration The patient's family states that prior to the operation during sleep she disturbed the entire household with the most terrifying choking noises and that she now sleeps without noise

Patients who are wearing tracheotomy tubes are in one sense ideal for the operation of muscle transposition, as the presence of the tracheotomy tube eliminates the first stage For reasons to be mentioned later, long-standing bilateral paralysis presents a different problem from recent paralysis In recent paralysis the cords are in an outward position, with the arytenoid cartilages widely separated This state prevails only for from three to six months In long-standing paralysis, the cords are contracted and shortened The interarytenoid muscles and fascia have become contracted and the arytenoid cartilages drawn much closer together than in recent paralysis

I have not seen an adequate or accurate description of the composite picture of the glottis the larynx, the aryepiglottic folds, the arytenoid cartilages and the vocal

in comparison with normal larynges It is apparent by the simple observations made with an ordinary laryngeal mirror There is considerable variation in normal human larynges For example, the male adult larynx is from 8 to 10 mm greater in its average anteroposterior diameter than the adult female larynx

With the idea of trying to get a better composite picture of all the changes that occur in the larynx after

bilateral recurrent nerve paralysis, I recently examined the larynges of five patients There is an apparent narrowing of the lateral diameter of the larynx The arytenoid cartilages are fixed in close approximation and lean more forward than normal The entire glottic opening seems more oval than in the normal larynx The sphincteric mechanisms of the larynx (the component parts of the mechanism of the so-called epiglottic reflex) are all seen to be in a contracted state This mechanism is made up of the epiglottis, the aryepiglottic folds, the arytenoid cartilages, and the interarytenoid fascia and muscles, combined

with the false and true cords These structures act as a sort of elastic cuff surrounding the opening of the larynx They are a portion of the defensive mechanism which protects the larynx against the entrance of foreign substances In conjunction with the suprahyoid muscles, which draw the larynx up behind the base of the tongue, they act to close the larynx during deglutition The epiglottis does not close the larynx like a trap door It is only one of several structures that protect the larynx during the act of swallowing

Thinking in terms of what happens in motor nerve paralysis of the extremities, one has only to go back to the initial symptoms of bilateral recurrent nerve paralysis in order to predict accurately what is ultimately going to develop in the larynx

The initial symptoms of bilateral recurrent nerve paralysis are loss of voice and loss of epiglottic reflex The former means paralysis of the muscles of phonation and the latter paralysis of the muscles of the defensive mechanism of the larynx The patient can only whisper, and any effort to swallow fluids results in a portion of the fluid entering the larynx, it is immediately expelled and effort to swallow is temporarily abandoned

Fig 6—Posterior view of larynx and upper part of trachea Some of the intrinsic muscles are shown A study of these muscles their attachments and the laryngeal cartilages will give a good understanding of the muscular function 1 epiglottis running downward and backward from which on either side is the ary epiglottic ligament (the little swellings on this ligament indicate the position of the cuneiform and corniculate cartilages) 2 superior cornu of thyroid cartilage 3 inner surface of thyroid cartilage 4 4 cricothyroid muscle showing different direction of its fibers 5 posterior surface of cricoid cartilage 6 cricoarytenoid muscle 7 upper tracheal rings

Fig 5—Anteroposterior section of larynx showing left half Mucosa has been removed from muscles The superior and recurrent laryngeal nerves are shown supplying the internal muscles 1 superior laryngeal nerve 2 external branch 3 internal branch 4 superior horn of thyroid cartilage 5 main branch of internal laryngeal nerve 6 epiglottis 7 8 corniculate cartilage 9 cut edge of thyroid cartilage midline 10 10 cricothyroid muscle 11 branch of recurrent nerve entering arytenoid muscle 12 section of esophagus behind cricoid cartilage 13 13 rings posterior 14 recurrent laryngeal nerve A branch of recurrent laryngeal nerve is shown entering cricoarytenoid muscle Immediately above the cricoarytenoid muscle the recurrent nerve enters the thyroarytenoid muscle and just above the latter it enters the thyroarytenoid muscle Only the external branch (2) of the superior laryngeal nerve enters any muscle All other branches go to the mucosa and are cut off as shown The recurrent nerve (14) supplies all the intrinsic muscles except the cricothyroid (10)

cords such as exists in cases of long-standing bilateral recurrent nerve paralysis It can readily be demonstrated by motion pictures of the larynges in such cases

If a patient dies in the first few days following such injury, death is usually due to drowning in his own secretions or to pneumonia of a foreign substance type. The defensive mechanism of the larynx returns to function more quickly than that of phonation. It is more primitive in origin and also is aided by the suprahyoid group of muscles, which are not affected.

These symptoms can have only two interpretations. 1 There is paralysis of the muscles of phonation. 2 There is paralysis of the laryngeal defensive mechanism, the inevitable consequences of which are (a) flaccid paralysis, (b) atrophy, (c) fibrosis and (d) contractures. That is exactly what happens in both the vocal and the defensive mechanisms and that is why the term bilateral abductor cord paralysis does not fit the situation.

The arytenoid cartilages are the gates that open and close the larynx. They act as sliding doors in the cleft that surrounds the laryngeal orifice. Furthermore, they have attached to them the vocal cords, which open and close with the gates. If one thinks of this sliding door effect as operating on a circular base like a roll top desk, the picture becomes more clear. In long-standing bilateral nerve paralysis, they have become locked together by the interarytenoid muscles and fascia, which have become contracted as a part of the general contractures that take place in all the elements of the sphincteric mechanism of the larynx. Not only that, but the base on which the sliding doors operate has become rusted and frozen, so to speak.

As a result of this locking together of the arytenoid cartilages, I have noticed a tendency in the first and third patients operated on for both cartilages and both vocal cords to be drawn to the same side by the pull of the omohyoid muscle. This condition of affairs presented a problem that I had not foreseen. Incidentally, it is a problem that the advocates of nerve suture have not foreseen. Even if nerve regeneration were to take

This is a purely mechanical problem and one that must be solved by purely mechanical principles. With long-standing paralysis one must consider doing a reconstruction of the glottic opening. If the sliding gates of a barnyard are tied together with rope, the simplest method of dealing with the problem is to cut the rope. The same thing can be done with the interarytenoid muscles and fascia. If the track on which

Fig 8—The omohyoid muscle attached to the arytenoid cartilage

those gates slide has become rusty and the wheels are frozen, it must be cleaned and oiled. If the capsule surrounding the crico-arytenoid joint has become contracted and the joint frozen, it must be divided to permit the cartilage to slide outward.

After the interarytenoid muscle and fascia have been divided and the joint capsule severed, it would seem important to displace temporarily the arytenoid cartilage outward as a means of preventing the recurrence of contracture by new-formed scar tissue. This can be accomplished by drilling a hole in the posterior border of the thyroid cartilage at the proper level and then passing a chronic catgut suture through this hole and through the arytenoid cartilage. When this suture is tied, it will temporarily anchor the arytenoid cartilage in an outward position. During the period required for the absorption of the catgut suture, opportunity is provided for the omohyoid to take over the task of future abductions of the cartilage. The operation of the foregoing ideas is somewhat speculative. If proper care is exercised in putting these suggestions into effect, no harm can be done. I believe it quite possible that better results may be obtained by following them. The omohyoid is a much stronger muscle than the crico-arytenoid posticus and therefore can exert more powerful pulls on the cartilage.

In cases of recent recurrent nerve paralysis, the arytenoid cartilage is found to be in an outward position. The cord is also in an outward position, and the sphincteric mechanism of the glottis has not become contracted. If the foregoing reasoning is rational, it would seem that the ideal time for muscle transposition is as early as possible. The idea is to get the omohyoid into operation before contracture has taken place. In cases of peripheral nerve lesions, orthopedic surgeons begin at once to apply counter measures to prevent contractures. Those methods are splinting in positions of function and passive motion. There is no conceivable means of applying splinting or passive motion to the

Fig 7—The inferior constrictor of the pharynx cut and the superior thyroid artery and vein tied and cut

place following nerve anastomosis, this problem would still be present, and it is improbable that the crico-arytenoid posticus muscles could develop strength enough to deal effectively with it. Nerve regeneration could not be expected to take place in less than six months and probably would not occur in less than one year. It is in that period that the fatal contractures enumerated take place.

muscles of the larynx. Therefore the question of time becomes tremendously important in dealing with motor nerve injury to the larynx. Motor nerve injury to the muscles of the larynx is no different in fundamental principle from motor nerve injury to the muscles of the arm, leg or other part. The principles that have proved helpful in the one should be beneficial in the other.

Every surgeon is familiar with the course of events following peripheral motor nerve paralysis. It is the

Fig. 9—Procedure in cases of early involvement reconstruction features omitted

same in all motor nerve paralyzes. At first there is flaccid paralysis of the muscles and loss of power to contract and then atrophy, fibrosis and contracture. This is exactly what happens in the larynx. The term bilateral abductor cord paralysis is in reality a misnomer. It does not describe the conditions prevail-

ing in the larynx. The surgeon has been accustomed to examining the vocal cords while forgetting the other structures in the larynx.

In the operation I have devised, effort has been made to follow as closely as possible recognized orthopedic procedures for the treatment of peripheral motor nerve paralysis. In the proposed plan of reconstructing the larynx in cases of long-standing paralysis and contractures, the methods of orthopedic surgeons have been modified only to fit different circumstances. In cases of old or neglected paralysis they divide stiff joint capsules, forcibly stretch others, cut contracting bands of fibrous tissue and splint extremities in positions of best function.

In dividing the crico-arytenoid joint capsule and in cutting the contracted interarytenoid muscles and fascia, the same methods are used. In drilling a hole in the border of the thyroid cartilage and passing a catgut suture through it and through the arytenoid cartilage and tying it tightly enough to displace the cartilage outward, I am simply applying a temporary splint which will suffice to hold it in a position of respiratory function while the omohyoid is becoming attached in such a position that it will exert passive motion with each inspiration as long as the patient survives. The splint is absorbed in two weeks.

Immediate nerve suture is recognized as a correct course in cases of severed peripheral motor nerves. For the reasons previously mentioned, for the reason that complete restoration of function is seldom or never obtained, for the reason that the recurrent nerve is small, difficult to find and difficult to suture and for the additional reason that the recurrent nerve is supposed to carry adductor and abductor fibers in two separate cords within its sheath, proper hook-up of neurons is a remote possibility. Undoubtedly in these reasons is to be found the answer to the high percentage of failures following nerve suture.

In a case of recent bilateral nerve paralysis, what should be done? In the past the surgeon has sat on the sidelines and hoped and prayed a sort of sick-at-the-stomach prayer that in a few days or weeks everything

would be all right. He has been delighted when in a few weeks the patient's voice began to return, only to sink to the depths of despondency when faced with the full facts of what has taken place.

From observations on the patients for whom muscle transposition has been done, I believe that the earlier it is done the better chance there is for a satisfactory result. It should require only a few days to determine whether or not real injury has occurred to both recurrent nerves. Just as soon as a decision can be made, a tracheotomy tube should be placed in the trachea, and as soon thereafter as is feasible muscle transposition should be effected. If the operation is done within the first three or four months following paralysis, reconstructive features should not be necessary, as contractures of a serious nature will not have developed. The omohyoid does not have to be trained to contract during inspiration. It does so automatically.

Occasionally nerve paralysis is only temporary. If, however, it is bilateral and has not cleared in two or three weeks and if stridor is present, the probability of recovery's taking place is quite remote. An experienced laryngologist could, in a majority of instances, predict with considerable accuracy what the course would be. Thus unnecessary operations could be avoided. Many operations for paralysis of the vocal cords must be performed in order for the surgeon to perfect a technic. Each case must be studied carefully prior to operation. The plan herein proposed for relatively recent involvement, plus the reconstructive features, should be applicable to all.

No one should undertake this operation without first acquiring an accurate knowledge of the anatomy involved. I suggest that any one who wishes to undertake it first go to an anatomic laboratory and do it, not once but several times. Don't send an assistant to the laboratory to learn the anatomy for you unless you plan to let the assistant perform the operation. No substitute for normal anatomy can be expected to function as well as normal anatomic structures. As a general

Fig. 10 (case 2)—The vocal cords in action

rule, in doing reconstructive operations the closer one approaches normal functions the better are the results obtained.

I have studied about twenty cases of bilateral recurrent nerve paralysis but have not had an opportunity to follow any case from its inception. I examined one patient the day following bilateral nerve injury. She died the following day from diabetes and hyperthyroid crisis. The cords were in the cadaveric position. The

arytenoid cartilages were widely separated and yet she had stridor and loss of function of the defensive mechanism of the larynx.

Prior to examination in the other cases, the paralysis had existed from six months to seventeen years. The twenty patients will be grouped into three classes on the basis of what I have seen, not what I have read.

1 A group in whom the cords are so contracted and closely approximated that tracheotomy has been necessary in order to prevent suffocation.

Fig 11—The new position of the omohyoid at the close of the operation

2 A group in whom the cords are also closely approximated but who are able to survive by leading very inactive lives.

3 A group in whom the cords do not come to rest in a midline position but about halfway between the positions of phonation and respiration.

In the third group, I have seen two patients. They could speak fairly well. The voice was a bit husky and monotonous. They could get sufficient air for ordinary activities. It is probable that some laryngologists would classify their condition as partial paralysis. Both have sufficient airway to lead ordinarily active lives, and both have very slight adduction and abduction of the cords. Both have stridor and also respiratory embarrassment on exertion. Both had thyroidectomy followed by the usual symptoms of bilateral nerve paralysis, namely, complete loss of voice, inspiratory stridor and loss of epiglottic reflex, there was gradual improvement in the voice after several weeks, and as the voice improved dyspnea and stridor became more pronounced. It is difficult for me to conceive of an equal degree of bilateral partial nerve paralysis occurring as the result of surgical trauma. Therefore I classify them as having complete paralysis without the usual degree of contractures.

I am of the opinion that the entire conus elasticus is immediately involved in the flaccid state that follows the injury. The opinion is based on observations on the only patient I have seen within forty-eight hours after paralysis occurred. Her stridor was of a different quality from that in cases of old involvement. It was more fluttery, a sort of flapping in the breeze, so to speak, and not the high-pitched crowing sound that is present with old involvement. With a mirror, the cords were observed to be flaccid and widely separated and the entire lining of the larynx seemed to vibrate on inspiration.

This opinion is supported by the fact that the muscular fibers of the conus elasticus are derived from

external division of the thyro-arytenoideus muscle, as are the muscular fibers of the membrana quadrangularis (fig 12), as shown by Negus.<sup>4</sup> It follows that the conus and membrana quadrangularis are involved in the flaccid state. The muscular fibers of these structures, being offshoots from the thyro-arytenoideus, are likewise supplied by the recurrent nerves.

It is probable that in the instances in which obstructive dyspnea has developed on the operating table immediately after bilateral paralysis, it has been due to the relaxed conus folding on itself, a sort of modified intussusception during strong inspiratory effort, rather than to contractures of the cords. The latter could not take place.

The musculus aryepiglotticus (fig 13) are offshoots of the interarytenoideus muscle. They contract in unison or as a part of the contractures of that muscle during both deglutition and phonation. These muscles are likewise supplied by the recurrent nerves. It is thus apparent that all the muscular structures of the larynx that are concerned in the acts of phonation and deglutition will be involved in, first, the flaccid state and, ultimately, the contracted state which follows bilateral recurrent nerve paralysis.

#### REPORT OF CASES

Three patients have been operated on with the method described. The complete technique of laryngeal reconstruction has not been used in any case, although a rather close approach to it was used in the second case. It has been worked out on the cadaver and will be tried and the results will be reported at a future time.

CASE 1—Sister B, aged 42, who was operated on for exophthalmic goiter in 1921, had a loss of voice, which lasted a few months, and then shortness of breath and stridor, which persisted. Exercise caused marked respiratory embarrassment. She lost weight, and eating was difficult because of shortness of breath.

In 1933 she had a recurrence of the goiter, which was removed. She did not gain satisfactorily after the operation.

Fig 12—Note particularly the muscle fibers of conus elasticus and membrana quadrangularis. In recent paralysis these membranes are flaccid later they are involved in the contractures. (Figures 12 and 13 are from Spalteholz, Werner, Hand Atlas of Human Anatomy Philadelphia J. B. Lippincott Company, vol. 3.)

and in the past two years dyspnea had increased and stridor become more pronounced. Stridor was pronounced during sleep.

The patient was small, weighing 100 pounds (45 Kg). The pulse rate was 84, the heart and lungs were normal and the blood pressure was 132/76. The vocal cords were difficult to examine but were fixed in the midline position. Stridor was pronounced on inspiration. Physical examination revealed no other abnormalities.

Operation was performed July 20. One-fourth grain (0.016 Gm) of morphine and  $\frac{1}{150}$  grain (0.0004 Gm) of atropine were given one hour before operation. Nitrous oxide and oxygen anesthesia was used. The patient's condition immediately became so alarming, stridor so pronounced and cyanosis so marked that the trachea was exposed for the purpose of inserting a tube. The patient's condition improved somewhat, and tracheotomy was postponed for the last step, as opening

Fig. 13—Note that the musculus aryepiglotticus is an offshoot of the interarytenoid muscle.

the trachea would increase the chances of infection in the wound. At the close of the operation, the trachea was opened and a number five tube inserted.

For two reasons this was not a satisfactory surgical experience. 1. Inhalation anesthesia had proved dangerous and unsatisfactory. 2. The tracheotomy wound naturally became infected and exposed the adjacent wound to infection. It was therefore decided to seek a more satisfactory type of anesthesia and that no other patient would be operated on without a preliminary tracheotomy.

In the two subsequent operations, pentothal sodium (sodium ethyl [1 methyl butyl] thiobarbiturate) was used intravenously. It produced satisfactory surgical anesthesia. It has an additional advantage in that the anesthetist's equipment is far removed from the operative field. I have considered using local anesthesia. It would offer opportunity to observe the action of the omohyoid muscle on the arytenoid cartilage. It is a most intriguing thought. I have been afraid to undertake its use because of fear that the manipulations of the larynx would set up paroxysms of coughing, under which circumstance one could not work. Also I fear the possibility of a blowout in the uncovered portion of the esophagus during such paroxysm.

The postoperative course of this patient was uneventful. Six weeks after operation she expressed a desire to be rid of the tracheotomy tube, stating that when she placed her finger over the opening in the tube she could breathe through her mouth much more easily than prior to the operation. The tube was removed, and the wound closed in a few days. She taught school half days during November and December 1938. On the

opening of school in 1939 she took a full day's work in a grade school. She has gained 9 pounds (4 Kg), can go for a two hour walk without fatigue or respiratory embarrassment, has a good speaking voice, and except for a slight inspiratory stridor, which still persists, one would not casually be aware of any abnormality.

On account of an extremely sensitive gagging reflex, it has been difficult to examine her cords satisfactorily. By training this difficulty has been overcome to a degree where the opening and closing of her left cord can be observed (the omohyoid was attached to the left arytenoid cartilage). More symptomatic improvement has occurred during the month of December than in any other month following the operation.

CASE 2—Mrs. S., aged 73, who was operated on for goiter eleven years before, had lost her voice except for a whisper for several months. When it began to return, difficulty in getting her breath developed. As the voice became stronger, respiration became more difficult. For the past ten years she had been more or less of an invalid. Going upstairs or up a slight grade was a laborious task on account of shortness of breath, and during the past year the symptoms had become worse. She had gradually lost 32 pounds (14 Kg) and stated that it was difficult to eat and breathe at the same time.

The patient was of poor color and poor nutrition. The eyes were normal, the teeth artificial and the tonsils normal. A pyramidal lobe  $1\frac{1}{2}$  inches long and one half inch wide, freely movable and extending up to the hyoid bone, was present. Pulsations in the carotid vessels were normal. In breathing there was the typical sound made by tracheal obstruction. The heart and lungs were normal. There was no tremor. The vocal cords were fixed in the midline position. The blood pressure was 142/70. Fortunately the vocal cords were easily visualized. They were contracted to almost complete approximation in the resting state and separated by a very narrow aperture on inspiration. She had marked stridor.

She was admitted to the hospital June 30, 1938. July 2 at 7 a. m. she was given one-fourth grain (0.016 Gm) of morphine and  $\frac{1}{150}$  grain (0.0004 Gm) of atropine hypodermically. She arrived in the operating room at 8 a. m. in such an extreme state of respiratory embarrassment with cyanosis and pronounced increase in stridor that tracheotomy was immediately done with local anesthesia and she was returned to her room. She went home on the fourth day. In two months she returned, her weight having increased from 113 to 129 pounds (51 Kg to 58 Kg) simply because she was able to eat and breathe at the same time.

The steps as previously described were carried out. Her arytenoid cartilage had become ossified and in an attempt to pass a needle through it the upright portion was fractured.

Fig. 14—Severing the interarytenoid muscle and fascia and anchoring the arytenoid temporarily to the thyroid cartilage.

It was a disturbing experience and I thought one calculated to defeat the purpose of the operation. However, a second suture was placed through the distal fragment and the muscle sutured to it.

A temperature of 102 F developed on the fourth postoperative day, rising to 103.2 F on the fifth day and the patient showed signs of bronchopneumonia. On the following day the temperature dropped to 99 F, with a subsidence of symptoms and recovery was speedy and uneventful.

These first two patients operated on belonged to group 2 of the preceding classification, the third belonged in group 1

CASE 3—Mrs J, aged 63, who had been operated on ten years previously for goiter with a loss of voice and gradual return, had the usual stridor and dyspnea. At the end of eight months dyspnea had become pronounced, several choking spells had occurred, during which she had become cyanotic and unconscious. Tracheotomy was performed at that time, and she had worn a tube for nine years.

The results of physical examination were unimportant except in two particulars. Her cords were unusually tense and closely approximated. She was wearing the largest tracheotomy tube I have ever seen. By placing the finger over the opening of the tube, one immediately realized that she could not survive on the air intake through the larynx.

Operation was performed Dec 2 1938. The muscle was transposed in the manner previously described. The postoperative course was uneventful and she was discharged in one week.

At the end of two weeks she reported that she could note no improvement. Examination of her cords revealed no change in position, there was no movement and moderate edema was present at the base of the left arytenoid cartilage. In three weeks she returned very happy and said that she had been able to smell food being cooked for the first time in nine years. She was also able to blow out a lighted match or a candle, which she had not previously been able to do. This meant, of course, that she was getting more air through the nose and mouth. (It is interesting that the first improvement noted by the second patient occurred at the end of two weeks, when she was able to blow her nose for the first time in eleven years.) At the end of five weeks, motion was developing in the left cord, but not sufficient to permit removal of the tube.

#### POSTOPERATIVE OBSERVATIONS

The difference between the margin of space separating the vocal cords that is sufficient to sustain life and that which is sufficient to sustain a person at ordinary activities is not great. Patients 1 and 2 have sufficient airway to sustain them at ordinary activities. Patient 3 has a good voice but as yet not sufficient airway. If in three or four months she has not been able to stretch the contractures so as to permit wide enough opening of the left cord for removal of the tracheotomy tube, the right omohyoid will be transposed and the contracted interarytenoideus muscle and fascia divided.

It was only after observing the progress in these cases and collecting others and comparing the larynges with normal ones that I realized that laryngeal reconstruction must accompany muscle transposition in order to succeed satisfactorily in all cases of long-standing involvement.

The operation in the second case was more successful than the others. In fact the patient has practically perfect restoration of the functions of phonation and respiration. Interestingly, a major portion of the atrophic fibers of the interarytenoideus muscle and fascia were separated from the left arytenoid cartilage in that case. No effort at such separation was made in the other two.

#### CONCLUSIONS

1 Transposition of the omohyoid muscle to the arytenoid cartilage in cases of recent bilateral recurrent nerve paralysis plus laryngeal reconstruction in cases of old involvement with contracture presents an entirely new approach to the solution of this perplexing problem.

2 Motor nerve paralysis of the larynx is not different in fundamental principle and pathologic changes from peripheral motor nerve paralysis in other parts of the body.

3 Recognized orthopedic and surgical procedures for peripheral motor nerve paralysis have proved beneficial in the treatment of laryngeal paralysis.

4 An accurate knowledge of laryngeal anatomy and function is necessary for success in these procedures. Bungle operations in this region are sure to bring both the operation and the operator into disrepute.

5 It is probable that persons now wearing tracheotomy tubes because of bilateral recurrent nerve paralysis can be relieved of that necessity and that others may be restored to active and comfortable lives.

6 Once a chordectomy, always a chordectomy. Therefore I believe chordectomies should be discontinued until the merits of muscle transposition and laryngeal reconstruction can be adequately evaluated.

7 It is too early to know what the final outcome of these operative procedures will be. It is not possible to draw final or statistical conclusions from three cases. The results so far justify their application to a sufficient number of patients for proper assay of the values. If in the future other patients are benefited to the same degree as the patients here reported on, the nightmare of bilateral nerve paralysis will have been plucked of most of her gray hairs.

### FATAL GRANULOCYTOPENIA FOLLOWING ADMINISTRATION OF SULFANILAMIDE

H A SHECKET, M D

AND

A E PRICE, M D

ELOISE, MICH

Nine cases of fatal granulocytopenia due to sulfanilamide preparations have been reported. Four of these cases came to autopsy and in two instances the bone marrow was studied. An additional fatality with conditions found at autopsy and on study of the bone marrow is here presented.

#### REPORT OF CASE

J D, a white man aged 45, was admitted to the William J Seymour Hospital May 31, 1938, because of a recurrent left inguinal hernia which had been present for twenty-five years, pain in the left groin of one year's duration, and a chronic cough productive of whitish sputum for fifteen years. A chancre twenty-five years before was followed by treatment with numerous injections of arsphenamine and mercury. The admission diagnosis was left indirect inguinal hernia, postoperative herniorrhaphy adhesions, chronic bronchitis and latent syphilis.

June 15 the patient was operated on for a left indirect inguinal hernia. The postoperative course was uneventful until June 25, when the patient experienced sudden, severe, knifelike pain in the right side of the chest anteriorly, associated with difficulty in breathing. Physical examination revealed a diminution of breath sounds over the left base and right lower lobe and impairment of the percussion note over the right base posteriorly. The temperature was 100 F, the pulse rate 110 and the respiratory rate 20. The following diagnoses were considered: early pneumonia, pulmonary infarction and pulmonary atelectasis. The following day the temperature rose to 102 F and the sputum was positive for pneumococcus type II. Sulfanilamide 120 grains (8 Gm) was given followed by 20

From the Departments of Pathology and Medicine, Dr William J Seymour Hospital.

The pathologic studies and diagnoses were made with the assistance and confirmation of Dr S E Gould, chief of the department of pathology of Eloise and Seymour hospital.

grams (13 Gm) every four hours. The next day, June 27, the sulfanilamide level of the blood reached 136 mg per hundred cubic centimeters. Culture of the blood yielded negative results. Films made on a portable x-ray machine showed no consolidation.

The patient's condition showed no change until July 2, when his temperature rose to 104 F, the pulse rate to 120 and the respiratory rate to 50. On this date the sulfanilamide level was 56 mg per hundred cubic centimeters of blood. The following day the patient appeared critically ill with dyspnea, cyanosis, stupor and profuse sweating. Breath sounds were diminished and tactile fremitus increased at both bases posteriorly. July 5 the patient was put in an oxygen tent. The blood count showed a hemoglobin content of 11.5 Gm, erythrocytes 4,010,000, leukocytes 13,450, polymorphonuclear leukocytes 77 per cent, lymphocytes 16 per cent and monocytes 7 per cent. July 7, med-

seen), monocytes 4 per cent, and eosinophils 2 per cent. Capillary fragility (tourniquet) test produced no petechiae. A smear of aspirated sternal bone marrow showed lymphocytes 49 per cent, eosinophils 1 per cent, basophils 1 per cent, eosinophilic myelocytes 1 per cent, blast forms 1 per cent, normoblasts 43 per cent, megaloblasts 4 per cent and polymorphonuclear leukocytes 0.2 per cent. The patient was given 10 cc of pentnucleotide and 2 cc of liver extract twice a day and in addition a transfusion of 600 cc of citrated blood was given. Two days later administration of pentnucleotide (10 cc) was increased to three times a day. Blood transfusions were given daily. July 16 a small ulcerative lesion was first noticed on the tip of the tongue. This lesion spread to the mid region of the tongue the next day. The patient died the morning of July 18 with a temperature of 107.8 F, a pulse rate of 140 and a respiratory rate of 50.

7/17	8.3	2.98	850		5	3	2	90					Ulcer of tongue
7/18													Patient died

ication could not be administered by mouth because of nausea and vomiting. The sulfanilamide level had now fallen to 0.8 mg per hundred cubic centimeters. Sulfanilamide 30 grains (2 Gm) in 300 cc of water subcutaneously twice a day was prescribed.

July 8 another roentgenogram of the chest, made on a portable machine, showed no consolidation. July 9, reexamination of the sputum revealed group IV pneumococci. A faint erythematous macular rash was seen over the upper abdominal and chest regions. The sulfanilamide level of the blood on this date was 4.8 mg per hundred cubic centimeters. Hemoglobin was 11 Gm, erythrocytes numbered 3,570,000 and leukocytes 13,550, with polymorphonuclears 84 per cent, lymphocytes 10 per cent, monocytes 4 per cent and eosinophils 2 per cent.

Sulfanilamide was discontinued July 11 because there was no improvement in the patient's condition and toxicity caused by the drug was feared. At this time the hemoglobin content had fallen to 9.5 Gm, the erythrocytes to 2,970,000, leukocytes to 8,500 and the sulfanilamide level to 4.8 mg per hundred cubic centimeters of blood. The next day the temperature, pulse and respiration rate dropped to 99, 96 and 30 respectively, although there was no appreciable change in the clinical appearance of the patient. That day, July 12, the blood picture first revealed a neutropenia with hemoglobin of 10 Gm, erythrocytes 3,100,000, leukocytes, 5,300, polymorphonuclears 56 per cent, lymphocytes 38 per cent, monocytes 4 per cent and eosinophils 2 per cent. July 13, however, there was another sharp rise in temperature to 104 and a mild jaundice of the scleras and skin developed. The blood picture showed leukocytes 1,900, polymorphonuclears 12 per cent, lymphocytes 82 per cent (some young lymphocytes

seen), monocytes 4 per cent, and eosinophils 2 per cent. Capillary fragility (tourniquet) test produced no petechiae. A smear of aspirated sternal bone marrow showed lymphocytes 49 per cent, eosinophils 1 per cent, basophils 1 per cent, eosinophilic myelocytes 1 per cent, blast forms 1 per cent, normoblasts 43 per cent, megaloblasts 4 per cent and polymorphonuclear leukocytes 0.2 per cent. The patient was given 10 cc of pentnucleotide and 2 cc of liver extract twice a day and in addition a transfusion of 600 cc of citrated blood was given. Two days later administration of pentnucleotide (10 cc) was increased to three times a day. Blood transfusions were given daily. July 16 a small ulcerative lesion was first noticed on the tip of the tongue. This lesion spread to the mid region of the tongue the next day. The patient died the morning of July 18 with a temperature of 107.8 F, a pulse rate of 140 and a respiratory rate of 50.

\* Believed to have taken an additional unknown amount of sulfanilamide over three more weeks.

Jaundice was present two days after sulfanilamide had been stopped. Although the hemoglobin and red blood cell count showed a progressive fall from early in the course of the acute illness, the leukopenia and neutropenia were not manifest until the day after the drug was discontinued. The patient died seven days after the withdrawal of the drug. In an attempt to

stimulate hemopoiesis 110 cc of pentnucleotide, 4 cc of liver extract and five transfusions, totaling 1,550 cc of citrated whole blood were administered in four days. The sulfanilamide used was prontylin (Winthrop) by mouth and sulfanilamide (Abbott) subcutaneously. During his hospital stay the only other drugs administered were codeine sulfate, phenobarbital, pitressin and acetylsalicylic acid.

**Necropsy**—Postmortem examination was performed four hours after death. The positive observations are presented

Fig 1—Superficial mucosal ulceration of tongue. Note colonies of bacteria in submucosal and muscular layers, scattered round cell infiltration and absence of polymorphonuclear leukocytes. Slightly reduced from a photomicrograph with a magnification of 50 diameters.

here. In the right pleural cavity there was 75 cc of clear straw-colored fluid. The upper and middle lobes of the right lung were a dark purple and edematous. The lower 4 cm of the right lower lobe showed a sharply delimited, slightly raised area of consolidation covered by a fibrinous pleural exudate. The consolidation measured 6 by 4 by 4 cm. On section this area was seen to be a reddish gray. A firm grayish-white partially organized thrombus was found in the lower branch of the right pulmonary artery. The thrombus was intimately adherent to the wall of the vessel. Microscopic examination showed extensive edema and congestion, with large areas of necrosis containing many colonies of bacteria but without associated inflammatory cell reaction. The few cells found were of the mononuclear (histiocytic) type.

The tongue showed a shallow ulceration with a dirty gray base which extended from the tip to the midportion of the organ. Microscopically a superficial loss of epithelium was seen. Many colonies of bacteria were present in the submucosal and muscular layers of this section. The inflammatory reaction was mild, characterized by a scattered infiltration of lymphocytes, plasma cells and histiocytes. Edema and congestion also were seen.

The cardiac portion of the esophagus presented several shallow ulcerations of the mucosa and scattered small yellow plaques. The microscopic picture was that of patchy necrosis and hemorrhagic extravasation in the mucosa. The remainder of the section showed edema and congestion with a mild infiltration of mononuclear cells.

The liver was larger and heavier than usual and weighed 2,400 Gm. The organ was a diffuse dark red and was engorged with blood. Sections showed hepatic congestion and edema with a moderate perlobular lymphocytic infiltration. A good deal of iron-containing pigment was demonstrated by the prussian blue stain. The iron pigment was present in clumps and in scattered Kupffer cells.

The spleen was larger and heavier than normal and weighed 250 Gm. This organ was also dark red, cut with increased

resistance to reveal a severely congested tissue. Microscopic sections showed hyperemia and quantities of iron-bearing pigment.

The kidneys were large and congested, with depressed scarred areas beneath their capsules. Microscopic examination revealed scattered hyalinized glomeruli, cloudy swelling of the tubules, aggregates of lymphocytes in the interstitial tissue, sclerosis with narrowing of the larger arteries and engorgement of all the blood vessels.

The bone marrow at the ends of the humerus and femur as well as of the vertebrae appeared yellow and fatty. Microscopic examination of the bone marrow from the end of the femur showed almost no cellular elements. The bone marrow from the end of the humerus showed moderate cellularity with a differential count of primitive cells 4 per cent, blast forms 40 per cent, myelocytes 6 per cent, lymphocytes and plasma cells 30 per cent, megaloblasts 5 per cent and normoblasts 15 per cent.

The gross pathologic diagnoses were embolism of the lower branch of the right pulmonary artery with infarction in the right lower lobe, acute hyperemia of the liver, spleen, kidneys and stomach, mucosal ulcerations of the tongue and esophagus, arterial nephrosclerosis, chronic cholecystitis. The microscopic diagnoses were pulmonary infarction, necrotizing bronchopneumonia, mucosal ulceration of the tongue and the esophagus with general edema and congestion, edema and congestion of the liver and walls of the stomach, hemosiderosis of the liver and spleen, arterial nephrosclerosis, chronic pyelonephritis, benign corticorenal adenoma, myeloblastic arrest of the cells of the bone marrow and granulocytopenia.

#### REVIEW OF REPORTED CASES

A review of fatal granulocytopenia included nine cases reported in American and English journals.

In Borst's<sup>2</sup> case more than 50 Gm of prontosil (the disodium salt of 4-sulfamido-phenyl-2'-azo-7' acetyl-amino-1'-hydroxynaphthalene-3,6' disulfonic acid) in

Fig 2—Submucosa of esophagus beneath an area of ulceration. Note inflammatory reaction consisting chiefly of lymphocytes, plasma cells and tissue monocytes and almost complete absence of polymorphonuclear leukocytes. Slightly reduced from a photomicrograph with a magnification of 500 diameters.

twenty-eight days was given to a white woman, aged 61, with *Escherichia coli* pyelocystitis. The first symptoms of toxicity were those of general discomfort and mild fever. The drug was discontinued the next day. Sore throat was noticed the following day, when the blood count showed leukocytes 1,225, polymorpho-

1 Footnote deleted on proof.

2 Borst J G G. *Lancet* 1: 1519 (June 26) 1937.

nuclear leukocytes 5 per cent, hemoglobin 70 per cent, erythrocytes 3,300,000. The patient died two days after therapy was discontinued, on which day the count was leukocytes 960 and polymorphonuclear leukocytes 1 per cent. Atelectasis of the left lower lobe was the only finding reported from the postmortem examination.

Fig 3—Necrotizing pneumonia with large colonies of bacteria, edema, hyperemia and little inflammatory reaction.  $\times 50$ .

In the Young<sup>3</sup> case 54 Gm of sulfanilamide was administered in eighteen days to a man aged 53 with acute articular rheumatism. A cutaneous rash was noted during treatment. One day before the drug was discontinued the white cells numbered 7,800 with 73 per cent polymorphonuclear leukocytes. Four days after the sulfanilamide was stopped the white cells numbered 1,800 with no polymorphonuclear cells. Death occurred five days after the cessation of the drug. Postmortem examination revealed a grayish membranous exudate over the pharynx with no polymorphonuclears seen microscopically. The liver weighed 1,555 Gm, the spleen 175 Gm. The bone marrow was aplastic and contained no granulocytes. Lymphocytes, megakaryocytes and nucleated red cells were seen.

In Model's<sup>4</sup> case 54 Gm of para-aminobenzene sulfonamide (proseptasine May and Baker) was given in eighteen days to a man aged 20 with acute rheumatic fever. Two days after the drug was discontinued the blood count was hemoglobin 45 per cent, erythrocytes 2,900,000 and leukocytes 600, gray spots in the pharynx were noted for the first time. Death occurred the following day.

Plumer<sup>5</sup> presented a case of subacute bacterial endocarditis in a woman aged 54 who during thirty-five days was treated with 45.3 Gm of sulfanilamide. After this time nausea and vomiting developed and the drug was discontinued. Three days after the sulfanilamide was stopped the erythrocytes numbered 3,580,000, the leukocytes 400 with no polymorphonuclear leukocytes. The following day a gangrenous infection of the mouth

and pharynx was noted. The leukocyte count was 1,600. The patient died five days after the drug was discontinued.

In the Berg and Holtzman<sup>6</sup> case 58 Gm of sulfanilamide in thirty-three days was given to a man aged 22 with acute gonorrhea. Treatment was continued despite numerous toxic reactions. The last blood count recorded hemoglobin 60 per cent, erythrocytes 2,600,000, leukocytes 1,600 with no polymorphonuclear leukocytes.

Bernstein's<sup>7</sup> patient, an infant aged 6 months, had bronchopneumonia, otitis media and erysipelas. She was treated for fourteen days, receiving 94 Gm of sulfanilamide orally and 35 cc of prontosil intramuscularly. After an interval of thirteen days treatment was resumed over a period of twelve days, the patient receiving 8 Gm of sulfanilamide orally and 35 cc of prontosil intramuscularly. Two days after resumption of treatment jaundice developed. Granulocytopenia was first observed three days after the final cessation of therapy.

Schwartz, Koletsky and Garvin<sup>8</sup> reported the case of a man aged 32 who received 566 Gm of sulfanilamide in twenty-one days of treatment for a penile ulcer—a possible chancroid. August 13 a blood count of 3,900 leukocytes and 4,140,000 erythrocytes was noted with no subjective complaints. August 16, the day the drug was stopped, the blood report was leukocytes 2,000 with no polymorphonuclear leukocytes and 3,410,000 erythrocytes, still with no subjective complaints. Typhoid bacilli (20 million) were given the following day to stimulate development of leukocytes. Following the typhoid treatment the temperature rose

Fig 4—Mononuclear cell reaction about a colony of bacteria in the lung. Note virtual absence of polymorphonuclear leukocytes. Slightly reduced from a photomicrograph with a magnification of 500 diameters.

from normal to 104.9 F and persisted. Four days after the drug was withdrawn sore throat and difficulty in swallowing were reported. Examination revealed a

necrotic ulceration of the mucosa in the tonsillar region. The scleras were icteric and the liver edge was palpable 3 cm below the costal margin. The patient died five days after sulfanilamide was discontinued.

The postmortem examination revealed hyperemia and edema of the larynx with a lymphocytic infiltration. The lungs, liver and spleen were hyperemic with

Fig 5—Bone marrow of the humerus. In addition to normoblasts there are leukoblasts, myelocytes, lymphocytes and plasma cells but no polymorphonuclear leukocytes. Slightly reduced from a photomicrograph with a magnification of 500 diameters.

large quantities of iron-bearing pigment. The cellular picture of the hemopoietic tissue was within normal limits. The differential count was myeloblasts 55 per cent, lymphocytes 35 per cent (with occasional plasma cells) and nucleated red cells 15 per cent.

O'Connell<sup>9</sup> reported the case of a seaman treated for chronic gonorrhea with 24.3 Gm of sulfanilamide over a period of seven days. Treatment was discontinued because of "acute catarrhal fever." Three weeks later the patient returned to the hospital with symptoms of granulocytopenia. Death occurred three days after onset of his acute illness. After death a partially filled bottle of sulfanilamide tablets was found among his effects. The changes found at autopsy were reported as agranulocytosis and edema of the glottis.

Mitchell and Trachsler<sup>10</sup> presented a case seen by them in which large doses of sulfanilamide were employed over a long period of time in the treatment of chronic infectious arthritis. A severe anemia, neutropenia and necrotic stomatitis developed and the patient died. The condition found at autopsy was not reported.

#### COMMENT AND SUMMARY

The pathologic changes in our case agree with those of the few postmortem examinations which have been made. The fundamental picture is that of a toxic granulocytopenia with arrest of the maturation of the blast forms of the myeloid series such as has been reported for other toxic drugs. The jaundice, the quantities of hemosiderin in the liver and spleen as

well as the bone marrow count support the impression that the anemia was of a hemolytic nature due to the toxic action of the sulfanilamide. We cannot agree with the opinion of some writers that this action on the bone marrow is due to specific idiosyncrasy. The quantity and the prolonged use of the drug we feel are the significant factors.

In these ten cases of fatal granulocytopenia, the doses of sulfanilamide preparations ranged from 35 to 64 Gm with an average of 50 Gm. The length of time that the drug was administered ranged from fifteen to thirty days with an average of twenty-seven days of therapy. Thus in all these cases large doses of the drug were administered over long periods of time. It is the impression of clinicians<sup>11</sup> who have had large institutional experience with the drug that the efficacy of sulfanilamide in a given condition should be demonstrable after from four to seven days. If no improvement is noted within that period the continued use of the drug is of doubtful value.

All the reviewed cases except that of Schwartz and his associates<sup>8</sup> showed toxic symptoms during the use of sulfanilamide. Toxic symptoms are very common during this therapy. Certain of these reactions, however, should be considered as warning signals, i.e., cutaneous eruptions, hyperpyrexia, jaundice, gradual fall in red blood cells and hemoglobin and an abrupt rise or fall in white blood cells. As has been suggested by Bannick and his associates,<sup>12</sup> if mild to moderate toxic symptoms appear decrease in dosage or cessation of the drug for a few days is advisable. If symptoms persist

Fig 6—Bone marrow of the humerus. Same as figure 5.  $\times 1000$ .

or recur after decrease or on resumption of the drug, permanent discontinuance of the therapy is indicated.

A close check on the blood picture was not made in most of these fatalities. Blood counts were not done frequently. Three cases were not brought under the care of the reporting authors until the granulocytopenic

10 Mitchell, A. G. and Trachsler W H. *J. Pediat.* 11: 183 (Aug) 1937.

state had been reached. The patients had been treated on the outside or had practiced self medication. Careful daily blood studies are indicated when sulfanilamide is used for any length of time.

Granulocytopenia was not manifest in six of the reported cases until from one to four days after the drug was stopped. In Young's case, in which blood counts were taken frequently, one day before the drug was discontinued the white cells numbered 7,800 with 73 per cent polymorphonuclears. In our case, two days before sulfanilamide was stopped leukocytes numbered 12,550 with 84 per cent polymorphonuclears, the day of discontinuance the white cell count was 8,500. Blood studies for a few days after cessation of therapy would seem to be a valuable procedure.

Sulfanilamide is an exceedingly valuable drug which is being widely used, yet, there have been relatively few fatalities reported. The drug should be administered only under careful supervision. The use of sulfanilamide in conditions in which its value is not established should be reserved for cases under institutional direction. Legislation is necessary to prevent dispensing the drug without prescription.

## STRONGYLOIDIASIS

VIRGIL E. SIMPSON, M.D.

LOUISVILLE, KY

The title of this paper describes an abnormal condition resulting from a parasitic invasion of the human body. It has been sixty-two years since Normand<sup>1</sup> chronicled his observations of the condition in the French soldiers returning from Cochin China (1876), but little has appeared in medical literature since. Bavy in the same year observed a large number of infested workers in the St Gothard tunnel and attempted some description of the parasite. In the United States the pioneer observer was Strong

### PATHOGENICITY

Debate continues to rage around the query "Are the parasites pathogenic?" So far as the animal experimental work may aid conclusion, it appears that Sandground<sup>2</sup> has demonstrated that they can cause symptoms. The failure to convict *Strongyloides* in the case of Cochin China diarrhea has perhaps been a factor in the rather general thought that the parasite causes no symptoms. Yet cases are found in the literature in which the symptoms are as definite as may be observed with infestation by other members of the nematode family. Likewise, reports of relief from such symptoms after the eradication of the larvae from the stools would appear as legitimate evidence of pathogenicity. Eosinophilia appears to be present in a percentage comparable to that in infestations by other nematodes. This argues an allergic response. This allergy shows some peculiarities. Sandground showed that the host organism produces no antigen against the filariform larvae themselves except when they undergo certain functional changes, such as maturation. When Rhabditis larvae are used as antigen, complement fixation is more uniform.

Pathogenicity of the parasite is often dismissed with the statement that "it usually produces little harm." This is in contrast to the opinion of Barlow, who classified the stages of strongyloidiasis as (1) a period of pruriginous cutaneous lesions, the result of larval invasion, (2) a latent period, (3) a period characterized by diarrhea and (4) a period of neurasthenia.

Ginsburg's<sup>3</sup> patient had been ill but three weeks when admitted to the hospital and died one month later. While necropsy was not performed, no other cause was found clinically to explain the death. In one of the most recent articles on the parasite Hinman<sup>4</sup> called inevitable the conclusion that the parasite is pathogenic.

### DISTRIBUTION

De Rivas<sup>5</sup> said that the parasite may be found in the "territories where the hookworm is prevalent." Since hookworm is found in 33 per cent of the population of eleven Southern states, according to Rhoads,<sup>6</sup> one may well wonder why strongyloidiasis is not more frequently reported.

De Rivas's observation does not parallel that of Keller,<sup>7</sup> who studied fifty-two counties in Tennessee and found hookworm in forty-three, with an incidence of 74 per cent. Several other intestinal parasites were noted, but not *Strongyloides*. Cadham<sup>8</sup> reported a case from Winnipeg and commented on the rarity of this parasite in Canada. It was estimated by Faust that 6 per cent of the clinic population of New Orleans was infested. Thonnard-Neumann<sup>9</sup> ranked the parasite in order of its frequency with other parasites as follows: Endamoeba twenty-eight cases, Uncinaria twenty-three, Trichocephalus twenty-two, *Strongyloides* seven and *Ascaris* four. Eusterman and Balfour<sup>10</sup> expressed the belief that infestation is not as rare as clinical reports would indicate and is widespread in the Southern states. Ginsburg reported the case of a woman who was born and had lived all her life in western Pennsylvania. Manson Bahr<sup>11</sup> expressed the opinion that the parasite has a worldwide distribution. Faust reported a 4 per cent incidence among the inpatient and outpatient hospital population in New Orleans, the incidence among the city population was stated to be much less, but no estimate was made. Faust and his associates<sup>12</sup> found a 4.6 per cent incidence in Puerto Rico in 1934 and expressed the belief that the distribution of *Strongyloides* approximated that of hookworm. Byrd<sup>13</sup> reported 0.37 per cent infestation in Athens, Ga., in 1936. Headlee and

Cable<sup>14</sup> examined 514 students of the junior high school and of Berea College, Berea, Ky., in 1936 and found infestation with helminths in 31.9 per cent. *Strongyloides* had a percentage incidence of 2.7. The students came from fifteen states and a few from foreign countries. Forty-eight of 120 counties of Kentucky were represented. Hinman<sup>15</sup> found eighty-five cases of infestation in Louisiana in 1937. No extensive study of cross sections of the population of the Northern states has been made, but it is not probable that the incidence is as high as in the Southern states. Cordi and Otto<sup>16</sup> attempted to explain this difference on the basis of a poor adaptability of both eggs and larvae to changes in temperature.

#### LIFE HISTORY OF THE PARASITE

The usual story is that *Strongyloides stercoralis* invades the human being much after the manner of the hookworm. 1. The skin or mucosa is penetrated by the filariform larvae, which pass into the venous circulation through the heart and enter the alveoli of the lungs, whence they migrate to the epiglottis and on to the intestinal tract. 2. They may enter the digestive tract direct and attach themselves to the mucosa of the duodenum or jejunum or enter the crypts and develop into adult worms. They exist as male and female.

The most common method of development, however, is the hatching of the eggs in the intestine and their passage from the canal as rhabditiform larvae, after which they enter the filariform, infective stage. On the other hand, the larvae may become transformed into male and female worms and the eggs from these females hatch as rhabditiform larvae, which molt after a few days and become the infective filariform larvae.

The life history of this parasite then offers two phases of development, (a) a parasitic or intestinal form and (b) a free-living or fecal form. The first is represented by the female worm only, which is one-twelfth inch long and reproduces parthenogenetically. The worm is translucent and hence may easily be overlooked when one is examining the intestine at autopsy with a hand lens. It is most easily found by scraping the mucosa and studying the material under the microscope with a two-thirds inch lens. Only actively motile embryos are found in the feces. Eggs are found only when the stool is obtained by catharsis. Keeping this fact in mind helps to differentiate hookworm from *Strongyloides* eggs. Stitt<sup>17</sup> dogmatically says "In fresh feces one finds hookworm eggs and *Strongyloides* embryos." When kept at a high temperature the embryos develop in the free-living or fecal form. The parasites are now found living as male and female and reproduce the larvae, which are capable of starting a parasitic generation in the original host or a new one by ingestion. Failing to reach the intestinal canal of some mammal, they die.

The adult worms are found in greatest numbers in the duodenum, and the number lessens in succeeding divisions of the small bowel; they are rarely found in the large bowel. The head of the female pushes into the crypts of the glands of Lieberkuhn, eggs are found

there as well as between epithelial cells and even as deep as the basement membrane. When the eggs hatch, the larvae may encyst and be found in intraglandular lymphoid tissue, even as far as the lymphatic follicles of the submucous coat. Adult worms have been found in the stomach at autopsy, and Ophuls<sup>18</sup> observed ova and rhabditiform larvae there as well. Eusterman and Balfour say that when infestation is heavy larvae may be found in large numbers.

#### CLINICAL PICTURE

Since the parasite has a bizarre career in the human body, making its domicile with equal adaptability in the stomach, duodenum, biliary passages, pancreatic ducts, ileum, jejunum, cecum, colon, cutaneous blood vessels, lungs and trachea, a description of a clinical syndrome becomes difficult. When the entry has been through the skin a reactionary erythema begins within twenty-four hours at the site of entrance. This increases in degree for another twenty-four or forty-eight hours and is made more annoying by itching. These symptoms appear to be much aggravated in sensitized persons. Varying degrees of irritation, even inflammation, in lung tissues appear, while a low grade infestation may cause no clinical phenomena. In the digestive tract, whether reached by the skin-lung route or by direct conveyance to the stomach and bowel, the clinical picture varies from no disturbance or a negligible one to severe, even fatal diarrhea. Wagner<sup>19</sup> reported a case in which bloody diarrhea was present and superficial ulcers were seen proctoscopically some 6 inches above the anal sphincter. Colitis may be caused by the penetration of the colonic mucosa by the filariform parasites.

In de Langen's<sup>20</sup> group leukocytosis, a low hemoglobin content, epigastric pain, intermittent diarrhea, low grade pyrexia and bronchopneumonia were listed. Faust's group showed a much less severe syndrome, alternating diarrhea and constipation appeared as the most common symptoms.

Urticaria is rather frequently noted in strongyloidiasis. Whenever it occurs it is thought to be the result of direct irritation by the larvae as they penetrate the skin. In the case reported by Cadham intermittent diarrhea, recurring urticaria and neurasthenia with edema, emaciation and progressive anemia were interesting features.

Obstructive jaundice resulting from *Strongyloides* larvae was reported by Nisbet.<sup>21</sup> The larvae were found in the feces and also recovered by transduodenal drainage. A convalescent period of three months was recorded. In the chronic states emaciation and anemia supervene, and edema may follow in their wake. Death may ensue from a massive infestation. As long ago as 1876 Normand reported five deaths in Cochinchina. Ophuls observed fatalities in temperate zones. Ginsburg has reported similar observations.

Hinman found abdominal pain to be the chief complaint in a group of eighty-five cases reported in 1937; it varied in intensity, location and character. Abdominal tenderness alone was described in twenty-nine and was localized in the right lower quadrant in eight, in only three was it diffuse. A tentative diagnosis of appendi-

citis was made in five. In twenty-six diarrhea was noted, the stools were bloody in fourteen. The average loss of weight was 14½ pounds (6.7 Kg). In only nineteen cases was the finding of *Strongyloides* incidental to admission to the hospital.

The diagnosis of strongyloidiasis, however, must be made through laboratory studies, interesting as clinical phenomena may be. Reasoning from analogy, one would expect an increase in the eosinophils, but it is interesting to note that Hensen<sup>22</sup> reported a series of cases of intestinal infestation of several varieties, but none of strongyloidiasis, in which there was no eosinophilia. By the same yardstick one is prepared for an absence of eosinophils in strongyloidiasis. Wagner<sup>23</sup> expressed the belief that a value of 50 per cent is not uncommon. Hensen reported a value of 82 per cent in another series. In Levin's<sup>24</sup> group of eleven cases the highest eosinophil count was thirteen, and in five the count was five or less. Hinman expressed the opinion that eosinophilia is more frequent with infestations by *Strongyloides* than with those by other helminths, except *Trichinella*. Both of these invade tissues rather constantly, and hence a more significant eosinophilia is expected.

Perhaps the question was best summed up by Faust<sup>2</sup> when he stated that there is marked eosinophilia as well as leukocytosis during the period of invasion, incubation and early oviposition, and that both decrease as the infestation becomes chronic.

Complement fixation tests have been studied by Cosack and Schmidt<sup>25</sup> and stated to be of little value. Cutaneous sensitization tests may be suggestive in a small percentage of cases. Study of feces is the easiest approach and when larvae are demonstrated suffices. The larvae are very motile. Care must be exercised in studying specimens, as vegetable fibers may be mistaken unless motion is observed. When the stool is formed the larvae will best be found by making a dent in the fecal mass, filling this with water and keeping it in an incubator for twenty-four hours. The larvae gravitate into this pool and are easily found under the microscope with a 16 mm objective (Kolmer and Boerner<sup>2</sup>).

Hookworm infestation is most likely to be confused with strongyloidiasis. The embryos of hookworm are usually found in the unhatched eggs. The parasite is easily found in the feces, the contrary being true of *Strongyloides*. But when one reflects that in the majority of cases the stools will be normal unless obtained by purgation, some other procedures must usually be followed. As it is known that the duodenum harbors the major number of the parasites, a simpler and surer way is a study of duodenal fluid obtained by transduodenal drainage. In every case that I have studied parasites have been found in the duodenum. This method should be followed in every case in which parasitic infestation is suspected. It serves as usefully in evaluating the efficacy of therapy. Relief should not be assumed from study of the feces alone. Until both feces and duodenal contents are normal, conclusion of eradication is unwarranted. In this detail it is well to remember the injunction of Cordi and Otto<sup>16</sup> that

intestinal specimens should not be stored in an ice box for as long as ten hours before examination for *Strongyloides*.

#### TREATMENT

The lack of appreciation of the pathogenic nature of strongyloidiasis exerted of course an influence on the interest in its therapeutics. Then, too, additional factor served to perpetuate a desultory concern with remedial measures. 1 Since the agent was a worm and the pharmacologies of the day listed a goodly number of vermifuges and vermicides said to be worth while, why search for a new one? 2 Though its habitat came to be known rather early disappearance of ova and larvae from the feces continued to be regarded as a measure of the efficiency of the drug used.

Thymol came to be used for this purpose, and in a single case reported in 1921 Wagner<sup>19</sup> described rather spectacular results. So enthusiastic was he that he described in considerable detail his method. He starved the patient for twenty-four hours and gave 30 grains (2 Gm) of thymol at the next bedtime, 8 ounces (236 cc) of magnesium citrate was given the following morning, and two hours later a second dose of thymol was administered. Food was permitted the following day. This procedure was repeated twice on the third succeeding days. Administration of a total of 120 grains (8 Gm) thus constituted the course of treatment, and the diarrhea was reported as having ceased in three days after the second course of treatment. Twelve years later Cadham,<sup>8</sup> impressed by the comparatively few reports in the literature of treatment with thymol, tried it on his patient and added him to the list of successes.

Thonnard-Neumann<sup>9</sup> reported the use of dihydranol (heptylresorcinol) in a series of thirty-one cases of helminthiasis, seventeen of infestation by *Strongyloides*, in all relief followed. The drug was administered in increasing doses, beginning with 0.9 Gm daily increasing to 1.8 Gm by the third day of treatment and continuing at this level for a varying period, apparently determined by results. Each daily dose was dissolved in olive oil, divided into three capsules and given one after each meal. The author concluded that the drug has a negligible toxicity and no so-called cumulative effects were noted up to a total dose of 17.5 Gm in a single series.

Gentian violet as a bactericidal agent was emphasized by Churchman in 1912. Its role as a helminthocidal agent was stressed by Faust<sup>28</sup> in 1929. His first observations were with the Chinese liver fluke, and the drug was given both orally and intravenously. He and his associates found that the drug was tolerated up to 35 mg per kilogram of body weight by both human beings and experimental animals. In 1930 he treated a series of patients under 10 years of age at Tulane University, the drug being given orally in doses of 0.5 Gm in enteric-coated tablets three times daily. The parasites were eradicated in the series with one exception and remained absent for three months. In 1932<sup>29</sup> he recommended a dose of 0.03 Gm (one-half grain) three times daily for ten doses. With a knowledge of some 200 patients who were treated with gentian violet, he had examined forty-seven after treatment and found all but two free from parasites. Only four had needed two courses of treatment. In a paper presented in 1937

he<sup>30</sup> listed as the most important chemotherapeutic agents for removing intestinal nematodes thymol, beta-naphthol, oil of chenopodium, carbon tetrachloride, tetrachlorethylene, santonin, hexylresorcinol and gentian violet medicinal. Of this group of anthelmintics admitted to the nobility, he classed gentian violet as a specific. He recommended that it be given in an enteric-coated pill in 0.06 Gm doses three times daily before meals for sixteen and two-thirds days. The implied virtue of the odd two thirds of a day remained unexplained. After stating that the drug is the only one found to be specific, he modestly concluded that it "frequently eradicates the organism." He stated that no satisfactory method of treating pulmonary strongyloidiasis had been devised.

In 1928 de Langen<sup>30</sup> had tied the drug in treating Strongyloides infestation in a dose of one-sixth to one-half grain (0.01 to 0.03 Gm) three or four times daily. The symptoms and eosinophilia promptly disappeared, but no mention was made in the translation concerning the disappearance of parasites from the stool.

Santonin, oil of chenopodium, glycerin and felicitis maris were all used in turn, with failure, by Kwa Tjaon Sioe<sup>31</sup>. Even a reduction in number of the larvae in the feces was not observed. Sioe observed that these drugs, together with emetine, antimony and potassium tartrate, methylene blue, eosin and gentian violet, did not rapidly kill larvae in cover slip specimens. He gave gentian violet orally and reported success. In his summary he wrote "The action of gentian violet is probably direct on the worms and in vitro it has not more effect than other drugs against the larvae." One finds it difficult to understand how a clinician can harmonize similar observations.

Cosack and Schmidt<sup>26</sup> reported a series of nine cases in which thymol, picric acid and oil of chenopodium were used with failure. Gentian violet was credited with favorable results in five of these. On analysis, however, the term favorable loses significance, as they said "Practically all the specimens were free from larvae" and again that "larvae were present in small numbers."

One may feel justified in concluding that unless a drug frees the canal of adult parasites, ova and larvae, it scarcely merits the confidence implied by the term favorable.

There appears to be no especial contraindication to the use of gentian violet. Nausea and vomiting are rather rare. Violet discoloration of the urine is still more rarely reported. It is claimed that the adult parasitic worm is very susceptible to its toxic effects, loses its attachment to the mucosa and passes in the feces. Singularly, the eggs and young larvae are more resistant. Yet more singularly, it appears that small amounts of the dye modify the indirect type of the parasite into the direct type, which may be said to minimize materially the likelihood of infestation before the parasites are actually killed. The dye stains the mucosa of the intestine a brilliant hue, this is thought to be a vital cytoplasmic reaction.

In 1926 De Rivas<sup>32</sup> described an intra-intestinal thermal method of ridding the intestine of parasites. The method consisted of flushing the bowel with a 30 per cent solution of magnesium sulfate introduced through an ordinary duodenal tube, this was followed by the

introduction of 500 cc of saline solution at a temperature of 46 C and in ten minutes by a second injection of magnesium sulfate solution. This procedure was to be repeated twice. The rationale of the procedure rested on the fact that intestinal parasites detach themselves from the intestinal wall and frequently are killed by an exposure of from five to ten minutes to a temperature of from 45 to 47 C (113 to 116.6 F). De Rivas<sup>32</sup> later described a modification of the method, in which he added an equal amount of glycerin to the preliminary sulfate solution. The added feature of dehydration was claimed to kill the parasites in a shorter period (from two to ten minutes).

Chopra and Chandler<sup>33</sup> said that no treatment known can be relied on for the relief of Strongyloides infestation. Levin<sup>24</sup> spoke of Strongyloides as deserving special mention because it had successfully eluded efforts at eradication. He expressed no doubt as to the pathogenicity of certain members of the family and stated that the digestive tract is more often the avenue of entrance than the skin. I did not read Levin's paper until some three months ago, during the preparation of this paper, and I was surprised to learn that he had found that the larvae can be killed almost instantly in vitro by "95 per cent alcohol, kerosene, glycerin and Gram's iodine solution." However, after trying kerosene and other agents he concluded that "no form of treatment has any permanent value."

Kudicke<sup>34</sup> tested a large number of dyes with a view to determining their chemical and pharmacologic effects on various parasites, including the larvae of Strongyloides. The concentrations necessary to produce toxic effects on the parasites precluded his carrying the tests into the field of observation on animals and human beings.

With such of the aforementioned information as was available up to 1936, the series of cases on which this report is based came under observation. Nine patients have been treated by the method to be described. Since there were no features of especial interest other than the treatment, only one case, the first of the series, will be detailed. Some patients responded promptly, with no recurrence, a result not obtained in the case reported.

The technic developed consisted in the following details. A saline purgative was administered one hour before supper. This was expected to act before the patient's bedtime. Breakfast was withheld the following morning. A transduodenal tube equipped with a Lyon metal bulb was introduced, the stomach irrigated and the tube allowed to pass into the duodenum. The duodenal contents were aspirated for the twofold purpose of securing a specimen for laboratory examination for parasites and to remove contents, thus lessening the dilution of the drug to be introduced into the bowel.

Compound solution of iodine was then introduced into the duodenum and the tube withdrawn. The dose finally fixed was 60 minims (4 cc) and was given on alternate days until neither the duodenal contents nor the feces showed ova, parasites or larvae. After two weeks the duodenal contents and feces were examined. If the results were negative, the patient was instructed to return in one month for another laboratory study.

The riddance of infestation by the drug given by mouth is believed possible but the results would surely
